An Eyelid Roller Forceps.....	500
Keloid Tumors of the External Ear. Three Illustrations.....	511, 512
Eosin-hamatoxylin.....	512
Gastrostomy according to Kader's Method. Four Illus- trations.....	605-607
Alcoholic Intoxication in a Young Child. Two Illus- trations.....	608, 609
Twin Strabismus Hooks.....	618
Method of Teaching Obstetrics. Eight Illustrations.....	634-639
Aids in Obstetric Teaching. Twenty-nine Illustrations.....	665-672
A Shade for the Welsbach Light.....	694
Aids in Obstetric Teaching. Twenty-two Illustrations.....	701-707
Aids in Obstetric Teaching. Twenty-four Groups of Figures.....	Facing 733
Aids in Obstetric Teaching. Twelve Illustrations.....	733-736
A Device for heating and keeping Hot Solutions for Spraying the Nose and Throat.....	760
Apparatus for Venous Transfusion. Two Illustrations.....	773
A Modified Nasal Snare.....	790

DR PEARCE BAILEY'S AND

DR. JAMES EWING'S ARTICLE ON ACUTE ASCENDING (LANDRY'S) PARALYSIS

Fig. I.—Normal human ganglion cell of the anterior horn of the spinal cord.

Fig. II.—Increase of pigment in the senile ganglion cell.

Figs. III, IV, and V.—Degenerative changes in the ganglion cell

## Original Communications.

### A CONTRIBUTION TO THE STUDY OF ACUTE ASCENDING (LANDRY'S) PARALYSIS.\*

By PEARCE BAILEY, A. M., M. D.,

ASSISTANT IN NEUROLOGY, YANDERBILT CLINIC;

ATTENDING PHYSICIAN TO THE  
ALMSHOUSE, WORKHOUSE, AND INCURABLE HOSPITALS, NEW YORK,

AND JAMES EWING, A. M., M. D.,

TUTOR IN HISTOLOGY, COLLEGE OF PHYSICIANS AND SURGEONS,

COLUMBIA UNIVERSITY, NEW YORK;

ASSISTANT PATHOLOGIST TO ROOSEVELT HOSPITAL.

ALTHOUGH it is nearly forty years since the French physician Landry described the disease which bears his name, and although since that time a considerable number of cases of this disease have been reported in different parts of the world, there are to-day many conflicting views of the pathology of Landry's paralysis.

The symptoms of the original case were an acute paralysis, ascending from the legs to the arms, and soon involving the bulbar muscles. The paralysis was unaccompanied by marked loss of sensation, nor did it involve the sphincters. The paralyzed muscles retained their faradaic excitability; the intellectual faculties remained unimpaired and fever was not prominent.

But after death no lesions were found in the nervous system to explain these rapidly fatal symptoms. Although the nerves were not examined, the results of a careful microscopic investigation of the spinal cord by several observers were absolutely negative.

Since that time some cases have occurred which were identical, both clinically and pathologically, with the original, and others have been reported in which more or less serious pathological alterations were found in the nervous system.

A study of the literature of this subject, together with the recent examination of a case of acute ascending paralysis in which the clinical symptoms were in exact agreement with Landry's description, but in which extensive lesions were found in the spinal cord, has led us to certain conclusions which are at variance with some recent conceptions of the pathology of the disease.

The object of the present paper is therefore twofold:

I. The description of a case of acute ascending paralysis, with special reference to its anatomical lesions.

II. A consideration of the cases of Landry's paralysis hitherto recorded, with a view of determining the pathological nature of the disease.

I.—The patient, M. S., a woman, aged thirty-six, housewife, born in Ireland, was admitted to Roosevelt Hospital November 25, 1895, during the service of Dr. Delafield, to whose courtesy we are indebted for the following history:

Family history negative. Personal history: Consid-

erable beer habit; never had articular rheumatism; denies all symptoms of syphilis and shows no evidences of this disease; has always been healthy. Present illness began on November 19th with an attack of vomiting without apparent cause, although she acknowledges a moderate but not unusual indulgence in beer on the previous day. Vomiting continued, till on the third day (November 22d) she went to bed exhausted. At this time she began to have occasional attacks of vertigo and dimness of vision, and on attempting to rise from bed fell to the floor in syncope. On November 23d she rather suddenly lost power in both legs, and on November 24th there was paralysis of the left arm with paresis of the right arm. Sensation was undisturbed.

*Condition on Admission.*—Color and nutrition good; tongue dry, slightly coated; pulse, 100, regular, tension normal; temperature, 101.4°; respiration, 28, regular; urine, acid, specific gravity, 1.030; no albumin; no sugar; a few hyaline casts. Physical examination of thoracic and abdominal viscera negative.

*Nervous System.*—Motion: Complete inability to move either legs or left arm; can flex toes of both feet perceptibly; retains slight power to move right arm. There is moderate left ptosis.

Sensation: Tactile sensibility normal; states accurately when and how legs are moved; no pain or tenderness in arms or legs.

Bladder and rectum: Control normal. Reflexes: Lost.

Electricity: Strong faradaic current elicited a diminished response in paralyzed muscles (November 28th).

November 26th.—Vomited repeatedly; sleepless.

27th.—Complained of headache and dyspnea.

29th.—Urine, fifteen ounces; contains a trace of albumin; no casts. Dyspnea increased rapidly. Dysphagia noted in the morning, which later became complete. Dysphonia marked and increasing. In the evening the patient became unconscious, and at 8.45 p. m., with severe dyspnea, cyanosis, and pulmonary oedema, she died.

*Autopsy* (Dr. Ewing).—November 30th, twenty hours after death. Body fat, pale; no oedema or noteworthy external markings.

Serous cavities: Normal. A few old adhesions over left lung.

Lungs: Moderately congested, decidedly oedematous; bronchi slightly reddened and coated with frothy mucus; bronchial lymph nodes normal.

Heart: Size, surfaces, chambers, and valves normal; muscle rather pale; aorta presents a very few atheromatous patches.

Liver: Moderately enlarged; consistence much reduced; surface and section smooth; centres of lobules deep red, not depressed; peripheries light-colored and fatty, but general outlines of lobules indistinct.

Spleen: Decidedly enlarged, rather firm, section deep red, trabeculae faintly visible; Malpighian bodies indistinct.

Kidneys: Moderately enlarged, soft; capsule not adherent; surface smooth; stellate veins congested; cortex slightly thickened and congested; markings regular; pyramids much congested.

Gastro-intestinal tract: Adrenals, ureters, and pancreas apparently normal (Peyer's patches not enlarged).

Muscles: Not examined.

Brain: Considerable distention of veins and sinuses of brain and dura. No thrombi. Pia and cortex rather

\* Read before the New York Neurological Society, March 3, 1896.

succulent. Sections through cortex, capsules, basal ganglia, medulla, and pons disclosed a large but not distinctly abnormal blood content; no gross lesions.

**Spinal cord:** There was the usual filling of the dorsal veins. Pia normal. Consistence of cord normal. On section, the white matter throughout seemed entirely normal. The gray matter appeared plainly outlined and the vessels slightly congested, but these features were not more prominent than is frequently found in normal cords. At one point in the gray matter of the cervical cord a minute red spot was found which could not be displaced, indicating the presence of extravascular blood.

**Anatomical Diagnosis.**—Congestion and cedema of the lungs; acute degeneration of liver and kidneys; acute hyperplastic splenitis.

**Diagnosis of the condition of the nervous system reserved for microscopical examination.**

The brain and cord were placed in Lang's fluid\* for forty-eight hours, the basal ganglia having been separated by Meynert's method, and the cord having been divided by transverse incisions at short intervals. The specimens were then washed in water and treated with successive alcohols of increasing strengths, tinged with iodine to remove all trace of sublimate, and finally mounted in celloidin and sectioned.

The stains employed were the eosin hæmatoxylin, Van Gieson's picro-acid fuchsine, Loeffler's alkaline methylene blue, Ehrlich's tri-acid mixture, Gram's and Nissl's.

The Nissl stain furnished the most satisfactory results and was the one chiefly employed. This stain is to be most highly recommended for the study of changes in the ganglion cells. Not only is its application simple, but it demonstrates better than any other method the minute structure of the cell.

After Nissl's method, the sections were gently heated in a one-per-cent. aqueous solution of methylene blue over a small Bunsen burner. They were then washed in water, decolorized, and at the same time dehydrated in strong alcohol (absolute is preferable), cleared in oil of organum, and mounted in balsam.

**Microscopical Examination.**—*Cauda equina:* The vessels of the cauda equina were filled with blood, but there was no thickening of their walls or infiltration of the circumvascular sheaths. The axis cylinders of the nerve fibres appeared normal, and there was no increase of the connective-tissue nuclei.

**Nerve roots:** The nerve fibres, so far as could be determined by the methods used, were normal. There was no increase of the nuclei of the neuroglia cells. In some of the nerve roots there was a slight circumvascular infiltration of small round cells.

**Pia mater:** There was some round-cell infiltration in the meshes of the spinal pia, especially about the vessels.

Peripheral nerve trunks were not examined.

**Spinal cord—gray matter:** The gray matter was extensively affected throughout the entire length of the cord, being much more involved in some areas than in others. The lesion consisted in intense congestion of all the blood-vessels, especially of the ramifications of the central branch of the anterior spinal artery. In the cervical region there were several capillary hæmorrhages, and some of the arterial twigs contained thrombi com-

posed of multinuclear leucocytes. Nearly all the vessels showed a pronounced circumvascular infiltration with small round cells (Fig. 1). In some places this infiltra-

FIG. 1.—Circumvascular infiltration of small round cells. Ven. of anterior horn.

tion had extended beyond the circumvascular sheath, and the small cells were gathered in such numbers as to form what may be properly regarded as milary abscesses. Furthermore, there was a diffuse cellular infiltration in the gray matter, which sometimes extended slightly into the white matter. At some levels congestion and exudation were so intense that nothing could be distinguished but the round-cell infiltration and the detritus of neuroglia and ganglion cells. Where the process had extended into the white matter, as was observed in the cervical region only, the fibres were absent and their places occupied in part by large mononuclear cells, with homogeneous or granular protoplasm.

The central canal appeared not specially affected.

Before detailing the degenerative processes in the ganglion cells, it may be well to briefly describe a normal human ganglion cell of the anterior horn as it appears when stained by Nissl's method (Fig. 1, Plate). The cell body under these conditions contains a number of chromophilic masses, larger and grouped concentrically about the nucleus, arranged in rows along the cell borders, and prolonged as slender rods into the dendrites. These bodies are not found in the axis-cylinder process.

The significance of these chromophilic bodies is not known, but they are believed to be a characteristic and normal element of the ganglion cell. Besides these bodies smaller granules are scattered through the cytoplasm, giving the appearance of a fine network. Some areas of diffuse, structureless, greenish pigment are often encountered in normal ganglion cells of the adult, a feature which is much more conspicuous in old age (Fig. 2, Plate). By this method of staining the nuclear membrane is distinct, and is separated from the deeply staining nucleolus by a clear area in which may occasionally be made out a fine granular network.

\* Distilled water, 2,000; chloride of sodium, 120; acetic acid, 120; bichloride of mercury, 60.

The abnormalities in the ganglion cells observed in the present case consisted principally in the partial or complete absence of the chromophilic masses (Figs. 3 and 4, Plate). In cells in which the lesion was least marked the absence of chromophilic bodies was noted only in the central portions of the cells. Other cells were seen in which the cytoplasm was entirely bereft of chromophilic bodies and their places were occupied by a multitude of fine, rather deeply staining granules, which gave to the cell body a very peculiar "dusty" appearance. Further, in many cells even the finer bluish particles were absent, and in these cells especially, less often in the others, the nuclear membrane was indistinct, irregular, or granular, and the nucleolus fragmented or absent (Fig. 5, Plate).

Finally, in the areas where evidences of exudative inflammation were most pronounced, many shrunken and irregular cell bodies and collections of deformed chromophilic bodies without visible cell nuclei were with difficulty to be recognized.

The fragmentation of cell processes, as observed by Oettinger and Marinesco, was occasionally encountered, but in such situations as to render its pathological significance uncertain.

While not insisting that our interpretation is entirely correct, we believe that the real chronological order of these degenerative changes in the ganglion cells has been indicated by the sequence of the above description.

*White matter:* Besides the few areas where the inflammatory process in the gray matter had extended into it, the only lesion of the white matter was a moderate circumvascular infiltration of the blood-vessels.

*The Topographical Distribution of the Lesion in the Cord.*—In the cervical region the lesion was most pronounced, and in many sections not a single ganglion cell had escaped extreme alteration or complete destruction.

In the lumbar and dorsal regions (Fig. 2) the changes

anterior horns remained in a fair condition of preservation.

The changes in the gray matter throughout the entire cord were but slightly marked in the posterior horns.

In the cervical region only, as before mentioned, some fibres of the white columns had suffered destruction by an extension of the inflammatory process from the gray matter.

The nerve roots in the upper dorsal and cervical segments showed considerable circumvascular infiltration, but their fibres were well preserved. Although the peripheral nerves were not examined, it is reasonable to suppose that any lesion which may have existed in them was secondary to the intense inflammation of the spinal cord.

*Medulla and brain:* The lesions in the medulla and pons were chiefly marked in the gray matter along the floor of the fourth ventricle and in that of the pons, although the white matter and periphery were not entirely uninvolved. The changes were similar to those described in the cord. The nuclei of all the cranial nerves were more or less damaged, those least affected being the sixth and seventh. The changes in the nuclei of the third nerves were chiefly in the ganglion cells which lie internally. The nucleus funiculi teres was but little affected. The basal ganglia showed the circumvascular lesions and numerous small foci of cellular infiltration. The internal capsule was intact, but the motor cortex presented the same small collections of round cells, and ganglion cells in the milder stages of degeneration. The temporo-sphenoidal lobes were normal. The marked lesions of the medulla extended slightly into the middle peduncles and the lateral lobes of the cerebellum.

FIG. 2.—Section of spinal cord dorsal region. Ganglion cells of Clarke's column only preserved.

were extensive, but the cells of Clarke's column were only slightly affected, and offered a sharp contrast to the intensely inflamed anterior horns.

In the sacral region and conus medullaris the lesions were least pronounced, and many ganglion cells in the

FIG. 3.—Lesion in cerebellum.

Throughout the cerebellar cortex (Fig. 3) were found lesions similar to those seen in the spinal cord. The layer of Purkinje's cells was in many of the convolutions dis-

placed outward from the nuclear layer, and in adjoining inflammatory foci some of these cells were absent.

No bacteriological examination was made either by culture or by animal inoculation.

Sections from various levels were stained by Loeffler's alkaline methylene blue and by Gram's method, but no bacteria were found.

*Summary.*—The foregoing case furnishes an exact clinical counterpart of the one originally reported by Landry, and presents symptoms regarded by subsequent authorities as essential in this disease—viz., an acute ascending paralysis, causing death by invasion of the bulbar nuclei, without marked sensory impairment, without involvement of the bladder or rectum, and with retained faradaic excitability of the muscles.

But, in contrast to his case and to a few subsequent well-authenticated examples of this disease, in the present instance the clinical symptoms are attributable to most extensive lesions, involving the whole cerebro-spinal axis, affecting chiefly the gray matter of the brain and medulla and the anterior horns of the spinal cord.

The character of the lesion was that of an acute exudative inflammation, with marked cellular infiltration of the circumvascular sheaths, degeneration of the ganglion cells, and obliteration of other structural elements.

That these lesions are but slightly marked in the sacral region will explain the integrity of the sphincters, and the fairly normal condition of the posterior horns, the sensory tracts, and the nerve roots accords with the absence of sensory symptoms.

## II. CONSIDERATION OF THE PATHOLOGY OF ACUTE ASCENDING PARALYSIS.

The literature which has grouped itself around the association of symptoms known as Landry's, or acute ascending paralysis, is considerable. Many cases have been assigned to this category which manifestly belong to simple polyneuritis; still others have been described which were nothing more than the ordinary disseminated or transverse myelitis. Some cases of general myelitis of rapidly ascending type seem partially to resemble the disease under discussion, and it is at present impossible to state whether or not they should properly be classed as Landry's paralysis. Such a case of ascending myelitis, of seven weeks' duration, which proved fatal, with evidences of involvement of the bulbar nuclei, has been reported by Schultz and Schultze (*Arch. f. Psych.*, 1881, xii, p. 457).

Two papers appeared in 1889 (Nauwerck and Barth, Ziegler's *Beiträge*, 1889, v, p. 1; Ross, *A Treatise on Peripheral Neuritis*, London, 1893, p. 16) which essayed to prove that the disease was essentially a neuritis. But, in support of this view, cases were included whether accompanied or not with satisfactory pathological reports. Such a view of the pathology of Landry's paralysis was not satisfactory to Hun, who, in a paper two years later, concluded that "acute ascending paralysis, defined so

as to exclude all cases in which the sensory symptoms are prominent, or in which marked bulbar symptoms are not present, must be regarded as a clinical entity for which no corresponding lesion has as yet been discovered." This view of Hun's is indorsed by Osler (*Practice of Medicine*, New York, 1895).

After a careful review of all the literature relative to this disease, we have been forced to the conclusion that this opinion will now admit of some modification, as we have found many well-recorded instances of the disease in which the ascending paralysis, unaccompanied by marked sensory symptoms, soon involved the bulbar nuclei, and in which adequate pathological changes were found in the nervous system. For the purpose of classification, we have arranged a table of cases of acute ascending paralysis which have run a fatal course.

Believing that satisfactory conclusions can be drawn only from those cases in which the report was clear on the essential clinical symptoms, and in which a microscopic examination of the nervous system had been made, only a small proportion of the cases reported as Landry's disease have been included in our tables. A few cases have been disregarded on account of clinical deficiencies, many because of the lack of proper pathological examination. The futility of considering cases in which the nervous system was not carefully examined microscopically will be evident to all who are familiar with the technical problems of nervous pathology. We may cite as an example our own case, in which with extensive lesions the spinal cord presented no changes which the naked eye could detect.

If, however, we are to enlarge the conception of Landry's paralysis, as suggested by Nauwerck and Barth, so as to include cases in which sensation was decidedly affected or completely lost, and in which the disease was distinctly subacute or chronic, with intervals of improvement, the doors are thrown open to a multitude of cases of neuritis, and Landry's paralysis becomes a disease of frequent occurrence and heterogeneous character.

An ascending paralysis which pursues a rapidly fatal course without prominent sensory symptoms is a clinical entity too distinct to warrant, without more definite reasons, such a widening of the conception of this disease. And while the strict adherence to a distinct clinical type may exclude cases in which, although the symptoms are not identical, the morbid process is essentially the same, the present lack of knowledge as to what Landry's paralysis really is renders such conservatism imperative.

The accompanying tables contain, therefore, all the reported cases of Landry's paralysis in which, in our judgment, the results of satisfactory clinical and pathological examination have been given. The references to the whole literature, from which the cases have been selected, may be found in the papers of Nauwerck and Barth and of Ross, and in reports which have appeared subsequently and up to the present time.

We have been unable to study cases published only in the Russian or Scandinavian languages or to obtain certain old monographs. With these exceptions, we believe that our review of the literature has been complete.

A detail of all the cases reviewed would render this paper unnecessarily cumbersome; we have appended, however, a list of some of the more important cases which do not appear in the tables, although a microscopic examination was made.\*

In addition, we have included several cases which have hitherto been spoken of, not as Landry's, or acute ascending paralysis, but as acute anterior poliomyelitis. The close clinical adherence of these cases to Landry's description will readily be seen, and their right to be

classed as examples of Landry's paralysis must be admitted. It may be stated also that with few exceptions all the cases given in the tables have been studied from the original papers.

For purposes of classification and comparison, the cases quoted have been divided into three groups:

Group I contains cases in which the result of microscopical examination was negative.

Group II contains cases in which lesions were found—(a) of cord alone, (b) of nerves alone, (c) of cord and nerves.

Group III contains cases which correspond clinically to the type of Landry's paralysis, but which have hitherto been classed as anterior poliomyelitis.

*Tables compiled from All the Cases found in the Literature of which the Symptoms were those of Landry's Paralysis, and in which Microscopical Examination of the Nervous System was Made.*

GROUP I.—Cases in which no Lesions were found on Microscopical Examination.

Numbness and loss of muscular sense; sensibility to cold and heat retained; pains in joints.	Normal.	Normal.	Normal.	P., 132. T., 99°.	Basal ganglia, medulla, cord, vagi, sciatic, sympathetic normal; acute hyperplastic splenitis.
Westphal, <i>Arch. fur Psych.</i> Male; adult; 1875, v, p. 28 days. 765.	Male; adult; 28 days.	Phthisis.	Gradual paresis and almost complete paralysis of legs and arms; dysphagia, dysphonia, asphyxia; right pupil parietic.	Moderately diminished; muscular sense and sensibility to heat and cold intact.	Not mentioned.	Slightly diminished.	Normal.	P., 94. T., 103°.	Cord, medulla, and nerve roots normal; acute hyperplastic splenitis.
Westphal, <i>loc. cit.</i> Male; 32 years; 1875, v, p. 28 days.	Male; 32 years; 28 days.	Five weeks' diphtheria.	Paresis, later paralysis of legs and arms; dysphagia, asphyxia.	Much diminished; muscular sense diminished; no pain.	Not mentioned.	Knee-jerks lost.	Normal.	P., 108. T., 100°.	Brain, cord, cranial nuclei, nerve roots, ganglia, and muscles normal; acute hyperplastic splenitis.
Kahler and Pick, <i>Arch. fur Psych.</i> Female; 12 years; 1880, 11 days. x, p. 313.	Female; 12 years; 11 days.	None.	Paresis, later paralysis of legs and arms; dyspnea, dysphagia, asphyxia.	Feet anesthetic; temperature sense delayed.	Not mentioned.	Lost.	Diminished reaction to galvanism.	P., 120. T., 101°.	Acute hyperplastic splenitis; cord normal; adhesions between spinal dura and pia; nerves not mentioned.
Kuemmel, <i>Zeit. f. klin. Med.</i> Male; 25 years; 1881, ii, p. 6 days. 273.	Male; 25 years; 6 days.	Fourth week of typhoid fever.	Paresis of arms and legs; paralysis of legs; total paralysis of all extremities; speech thick; double facial paralysis; dysphagia, dyspnea, asphyxia.	Normal.	Not mentioned.	Normal.	Normal.	P., 80 to 150. T., normal.	Bilateral hemorrhage of medulla (immediately ante mortem?); cord normal; nerves not mentioned.
Strumpell, <i>Arch. fur Psych.</i> Male; 22 years; 1883, xiv, p. 15 days. 353.	Male; 22 years; 15 days.	None.	Legs, arms; cyanosis, asphyxia.	Pain and tenderness; sensibility normal.	Normal.	Lost.	Not given.	P., 140 at end. T., 103°.	Cord normal; nerves not examined.
Mann, <i>Med. Chron.</i> Male; 1887, 49 years; vi, p. 99.	Male; 49 years; 9 days.	None.	Legs, arms; dysphagia.	Numbness.	Normal.	Lost.	Retained.	Normal.	Spleen normal; cord, medulla, and brain normal; nerves not examined.
Greppin, <i>Cor. respblat. schweiz. Aerz.</i> Female; 29 years; 1892, p. 517.	Female; 29 years; 19 days.	Patient insane.	Paralysis of one leg; then of the other; then of one arm, then of the other arm; asphyxia.	Not given.	Retention of urine.	Not tested.	Not given.	No fever.	Brain, cord, peripheral nerves, spinal ganglia, and nerve roots found healthy.
Ormerod, <i>St. Bartholomew's Hosp. Rep.</i> Male; 20 years; 1892, xxxiii, p. 137.	Male; 20 years; 8 days.	Onset after prolonged swimming.	Paralysis first of legs, then of arms, then of respiration; paralysis of left facial, orbicularis palpebrarum of both sides, and of orbicularis oris; uvula deflected; asphyxia.	Normal.	Normal.	Absent.	Normal.	Normal; pulse not given.	Spleen large, soft; sciatic and vagus normal, stained by Weigert; picrocarmin, aniline blue black; spinal cord, medulla, and cortex normal.
Ormerod, <i>loc. cit.</i> Male; 40 years; 17 days.	Male; 40 years; 17 days.	Alcoholic. Influenza?	Paraplegia and atrophy; paralysis of left arm, less in right; asphyxia.	No pain, but muscles tender on pressure; difficulty in sensation impaired in both legs, less affected in arms.	Constipation; no urine; micturition.	Re-flexes absent in arms; knee-jerk not tested.	Normal.	T., 98° to 101°.	Nerves and cord stained with osmic acid. Pal. picrocarmin; all normal except in one vagus (Müller's fluid), in which "Elbow did not take" Weigert well, and stained too deeply in carmin.
Ormerod, <i>loc. cit.</i> Male; 33 years; 16 days.	Male; 33 years; 16 days.	Alcoholic?	Paraplegia, dysphagia.	Impaired in legs and arms; pain in back; girdle sensation.	Incontinence of urine; constipation.	Absent.	Not used.	T., 99° to 102°.	Spleen large, soft; cord (Müller's fluid) aniline blue black, normal; anterior tibial nerve (Müller's fluid) and cauda equina osmic acid both normal.
Watson, <i>Brit. Med. Jour.</i> Male; 52 years; 1892, ii, p. 1286.	Male; 52 years; 8 days.	After lying on damp ground.	Paraplegia ascending and ending in respiratory paralysis; dysphonia, dysphagia, asphyxia.	No pain or anæsthesia.	No incontinence.	Absent.	Not mentioned.	Not given.	Histology (no details) of cord negative; nerves not mentioned.

References.	Sex, age, duration.	Etiology.	Paralysis.	Sensation.	Spincters.	Reflexes.	Electricity.	Pulse and temperature.	Autopsy.
Albu, <i>Zeit. f. klin. Med.</i> , 1893, xxiii, p. 387.	Male; 46 years; about 2 weeks.	None.	First paraplegia, then paralysis of arms; dysphagia, dysphagia, asphyxia.	Normal. "Intense tenderness of whole body," most marked in neck.	Normal.	Absent.	Not tried.	Normal; excessive sweating.	Nerves, cord, and spleen normal; bacteriological examination of cord, nerves, and blood (sowed on agar) negative.
Leube, <i>Special Diagnose der Krankheiten</i> , Leipzig, 1893, p. 142.	Female; 26 years; 8 days.	None.	Paralysis of legs and arms; dyspnoea, tachycardia, dysphagia, double facial paralysis; lagophthalmos.	Absolutely intact; pain in back.	Paralyzed at close of illness.	Lost.	Normal.	No fever. P., 150.	Absolutely negative (all specimens in Müller's fluid).

GROUP II (a).—Cases in which Lesions were found in the Spinal Cord.

Eisenlohr, <i>Virchow's Arch.</i> , 1878, lxxiii, p. 73.	Male; 42 years; 9 days.	Not stated.	Paresis simultaneous of arms and legs; dysphagia, dysphonia, asphyxia.	Nearly normal.	Normal.	Lost.	Normal.	P., 136. T., 98°.	In pons and medulla small foci of round cells about vessels and in tissues; ganglion cells "shining" and "swollen"; capillary hemorrhages; central canal and vicinity infiltrated with round cells; peripheral nerves normal; spleen, acute hyperplastic splenitis.
Ross, <i>Dis. of Nerv. Sys.</i> , 1883, i, p. 905.	Female; 21 years; 5 days.	Syphilitic.	Paralysis of legs; paresis of arms; later paralysis of all extremities; dyspnoea, asphyxia.	Not materially affected.	Not mentioned.	Not mentioned.	Not mentioned.	Not mentioned.	Disappearance of some ganglion cells; increase of nuclei; dilatation and congestion of blood-vessels.
Roussel, <i>Arch. de med. nav.</i> , 1883, xxxix, p. 370.	Male; 39 years; 6 days.	None.	Arms, legs; dysphagia, dysphonia, asphyxia.	Diminished; numbness and tingling.	Normal.	Not given.	Not given.	Normal.	Vascular lesions in cord; degeneration of ganglion cells; nerves not examined.
Hoffmann, <i>Arch. f. Psych.</i> , 1884, xv, p. 140.	Female; 36 years; 14 days.	Not mentioned.	Paresis of legs, then of arms; dysphonia, dysphagia, asphyxia; right ptosis; no atrophy.	Formication, but no pain or anesthesia; tinnitus aurium.	Retention of urine at the end.	Plantar reflex normal; knee-jerk lost.	Faradaic reaction diminished in right facial only.	Not mentioned.	Round cells along vessels of meninges and some vessels in "nerve substance," from dorsal cord to upper medulla; more marked in cord; ganglion cells "shining" and "swollen" and nuclei often obscure; small capillary hemorrhages in cervical and dorsal cord; nerve roots negative.
Immerman, <i>Nerv. Centr. u. periph.</i> , 1885, iv, p. 304.	Male; 22 years; 4 weeks.	None.	Ascending paralysis of lower and upper extremities; bulbar symptoms later; asphyxia.	Normal.	Paralytic.	Lost.	Normal.	Moderate fever.	Cellular infiltration of walls of vessels; disappearance of ganglion cells; lesion limited to anterior horns of gray matter of entire cord; peripheral nerves and muscles normal.
Curschmann, 1886, <i>Verh. der V. Cong. in Med.</i> , p. 473.	Male; 36 years; 9 days.	Typhoid fever.	Paresis, later paralysis of legs; paresis of arms, later bulbar signs; slight return of motion in legs day before death.	Tenderness along spine; no other points mentioned.	Normal.	Lost.	"Unsuccessful."	P., 140. T., 104°.	No report on changes in cord except that in white substance were round masses of bacilli which, cultivated and inoculated in rabbits, "proved positively their typhoid nature."
Ketli, <i>Wien. med. Blatt.</i> , 1887, x, p. 250.	Male; 30 years; 4 days.	None.	Legs, arms, respiratory muscles.	Unaffected.	Normal.	Diminished.	Normal.	Presumably normal.	The changes in the spinal cord were those of acute anterior poliomyelitis; no other details.
Iwanow, <i>St. Petersburg. med. Woch.</i> , 1888, v, p. 393 (2 cases).	Age and sex not stated; 8 and 11 days.	None.	Ascending.	Slightly affected in one case only; no pain.	Normal.	One case, not stated; one case, right knee-jerk lost.	Not used.	Pulse not stated; no fever.	Similar changes in both cases; many foci of small round cells regularly arranged along vessels of gray matter or grouped between ganglion cells; destruction of ganglion cells; fibrinlike exudate around vessels; nerves not examined; no bacteria seen by Gram's stain.
Hlava, <i>Ref. in Schmidt's Jahrbuch</i> , 1891, 232, p. 244.	Female; 36 years; 4 days.	None.	Sudden loss of power in arms and legs.	Not stated.	Not stated.	Not stated.	Not stated.	Fever.	No gross changes of lumbar cord and corpora quadrigemina; small-celled infiltration, especially in anterior and posterior horns and Clarke's columns; white matter normal; vessels everywhere dilated; cranial nuclei (xii, xi, x) involved; in ulnar and sciatic nerves were found mast cells in the nerve sheaths, but no degeneration.

References.	Sex, age, duration.	Etiology.	Paralysis.	Sensation.	Sphincters.	Reflexes.	Elec- tricity.	Pulse and tem- perature.	Autopsy.
Oettinger and Marinisco, <i>San. ital.</i> , 1895, No. 6.	Male; 20 years; 3 days.	During variola.	Paralysis ascending to arms; asphyxia.	Diminution of all forms of sensation.	Reten- tion of urine.	Lost.	Not stated.	T. that of vari- ola.	Dorso-lumbar cord soft; capillary hemorrhages; nerves of lower limbs normal; changes in cord follow vascular distribution; vessel walls thick and filled with leucocytes containing basophilic granules; thrombi in some vessels; coeal band in ganglion cells rarely, and in circumvascular spaces and leucocytes frequently; coeal also in central canal; no cultures; nerve cells show degenerative changes; lesion most marked in gray matter; most severe in dorso-lumbar cord, though present in cervical region, medulla, and pons.
Reulinger, <i>Mil. anal.</i> , 1896, 23 years; No. 27, p. 11 days; 213.	Male;	Malaria?	Paraplegia; later pa-ralysis of all four extremities; dysphagia, dysphonia, asphyxia.	Pains in legs worse on movement; no loss of sensi- bility.	Normal.	Abol- ished.	Not given.	P., 96. Normal.	Acute hyperplastic splenitis. Spinal cord (Nissl): inflammation in central branch of anterior spinal artery; no thrombi; few streptococci seen in section; spinal cord inoculated in bouillon gave pure culture of <i>Streptococcus luteus</i> . Injected in rabbits—no effect.
Marie and Mari-nesco, <i>Rev. d. sci. med.</i> , 1896, 7 days; 93, p. 134.	Male;	None.	Ascending to bulbar muscles.	Lost in legs.	Reten- tion of urine.	Not given.	Not given.	Not given.	Softening in anterior horns of cord; hemorrhages in fourth ventricle; disappearance of nervous elements in anterior horns and infiltration of leucocytes; bacteria in sections resembling anthrax.
Bailey and Ewing (pres- ent article).	Female; 36 years; 10 days.	None.	Paralysis of legs, then of right arm, with paresis of left arm; left ptosis; dyspnea, dysphagia, dysphonia, asphyxia.	Normal; no pain.	Normal.	Lost.	Re- tained.	P., 100. T., 101.5.	Acute poliomyelitis of spinal cord and medulla; vascular and exudative changes in motor cortex, basal ganglia, and cerebellum; degeneration of ganglion cells; slight vascular changes in nerve roots; peripheral nerves not ex- amined; acute degeneration of viscera.

## GROUP II (b).—Cases in which Lesions were found in the Peripheral Nerves.

Dejerine et Guetz, <i>Arch. de physiol.</i> , 2d series, t. iii, 876, p. 312.	Male; 45 years; 5 days.	None.	Complete paralysis of legs, later of arms; dyspnea, asphyxia.	Pains in legs and arms; sensa- tion to touch normal.	Reten- tion of urine.	Not stated.	Not stated.	P., 100. T., 102°.	Spinal cord (chromic acid, carmin) found normal; degeneration of fibres, with increase of nuclei in neuroglia, in some of the anterior nerve roots.
Putnam, <i>Boston Med. and Surg. Jour.</i> , 1889, p. 159.	Male; 28 years; 7 days.	None.	All four extremities; no bulbar signs until the end, then dysphagia and dyspnea.	Pains over whole body; numb- ness of feet.	Not stated.	Not stated.	Not stated.	Normal.	Acute hyperplastic splenitis; peripheral neuritis; cord not exam- ined.
Eisenlohr, <i>Dent. med. Woch.</i> , 1890, No. 38, p. 841.	Male; 18 years; 8 days.	Three weeks previously fever and headache.	Paralysis ascending, involving medulla.	Parasthesia; sensibility and muscular sense retained; nerve trunks sensi- tive to touch; no pain.	Normal.	Lost.	Normal.	Normal.	Blood sterile on gelatin, and mi- croscopically contained no organ- isms; spleen very large; spinal cord normal; degenerated fibres in right hypoglossal and right phrenic, in anterior roots of cer- vical nerves, and in other pe- ripheral nerves; no changes in posterior roots; bacterial stains negative in nerves; thorough bacteriological examination of spleen, cord, and nerves nega- tive.
Hun, <i>N. Y. Med. Jour.</i> , 1891, liii, p. 609.	Male; 45 years; 12 days.	None.	Paralysis of all ex- tremities and left facial nerve; dysphonia, dysphagia, asphyxia.	Normal; no pain.	Reten- tion of urine.	Ab- sent.	Normal.	Normal. Pulse regular, rapid.	Slight cerebral and spinal menin- gitis; infiltration of walls of some veins of spinal pia mater, and degeneration of some fibres of anterior roots of cauda equina; nervous system otherwise normal; cultures on agar from brain, medulla, and cord nega- tive; no bacteria seen in tissues.

## GROUP II (c).—Cases in which Lesions were found in both Spinal Cord and Peripheral Nerves.

References.	Sex, age, duration.	Ætiology.	Paralysis.	Sensation.	Spine- ters.	Re- flexes.	Elec- tricity.	Pulse and tempera- ture.	Autopsy.
Eisenlohr, <i>Deut. med. Woch.</i> , 1890, xxxviii, p. 841.	Female; 59 years; 17 days.	None.	Paralysis ascending from legs to medulla.	Pain in legs and back; diminished sensation.	Reten- tion of urine.	Tri- ceps reflex only, re- tained.	Reac- tion to fara- disin- in arms and in- ter- costals; other mus- cles not tested.	Normal.	Pulmonary tuberculosis; spleen soft, not enlarged; anterior nerve roots degenerated; cord normal, except a focus of swollen axis cylinders and degenerative products in 11th and 12th dorsal segments; posterior roots normal. Bacteriological examination: 2 cultures, No. 1 occurring in all organs, <i>Staphylococcus pyogenes aureus</i> , No. 2 from spleen and sciatic nerve only, <i>Staphylococcus cereus</i> (Passet); sections contained a few bacilli and cocci, but no tubercle bacilli.
Centanni, <i>Ziegler's Beil.</i> , 1890, viii, p. 358.	Male; 7 days.	None.	First legs, later arms and diaphragm; dysphagia, paralysis of obicularis palpebrarum; pupils normal.	Pain in legs and back.	Normal.	Ab- sent.	Not tried.	T. nor- mal.	Nerves: vessels prominent and surrounded by exudate; nerve-fibres not much altered. Cord: leptomeningitis and inflammation around the central canal; atrophy of peripheral fibres; other parts of nervous system normal; in all peripheral nerves there is a bacillus in large numbers; cylindrical, with rounded ends, without spores or special grouping, usually found in endoneural lymph spaces, not found elsewhere; no cultures made.
Giuzetti, <i>Rif. Med.</i> , 1894, ii, pp. 5, 19, 31.	Male; 19 years; 9 days.	Exposure to wet.	Paresis; then paralysis of legs, then of arms; dysphagia, dysphonia, asphyxia.	Formication; pain in median and trigeminus trunks on pressure; some tenderness in muscles; pain over vertebral spines.	Reten- tion.	Ab- sent.	Not given.	P., 120. T., 99°.	Spleen large and soft; disintegration of fibres of cord most marked in lumbar region, absent in medulla; ganglion cells cloudy with indistinct nuclei; about vessels a ring of granular substance, not staining like fibrin; recent punctiform hemorrhages in medulla and pons; degeneration of anterior and posterior spinal roots, most marked anteriorly. Peripheral nerves: multiplication of nuclei of neurilemma; some vessels of nerves surrounded by leucocytes. Bacteriological examination: Rabbit injected with emulsion of spinal cord and spleen pulp, result negative; cultures from brain, cord, sciatic nerve, heart's blood, spleen, mesenteric glands, urine, on various media, all negative except 2 tubes from sciatic and 1 tube from cord which grew a chromogenic bacillus; no bacteria seen in sections.
Ballet, <i>Med. Week</i> , 1895, iii, 526.	Male; 33 years; 7 days.	Influenza.	Of legs, then of arms; dyspnoea, cyanosis.	Nearly normal.	Not men- tioned.	Lost.	Not men- tioned.	Fever.	Spinal cord: circumvascular changes, especially around the anterior horns; degeneration of nerve cells, shown by Nissl's method; the anterior roots and peripheral nerves were "the seat of lesions without special features." Cultures from brain and medulla were negative; no bacteria seen in tissues.

## GROUP III.—Cases hitherto described as Acute Anterior Poliomyelitis, or Infantile Spinal Paralysis.

Rissler, <i>Nord. Med. Arkiv.</i> , 1888, xx, p. 22.	Child; 44 years; 6 days.	Epidemic in Stockholm.	First of left leg, then of right; arms free; right pupil larger than left.	Pain in legs; sensibility normal.	Bladder normal; constipation.	Ab- sent.	Not given.	Not given.	Spleen soft. Spinal cord: degeneration of ganglion cells; nerve fibres of gray matter and anterior columns of white matter are degenerated; proliferation of glia cells; occasional hemorrhages; vessels increased in size and number; circumvascular infiltration; vascular changes almost entirely limited to gray matter; degeneration of anterior roots; degeneration of both hypoglossi and one vagus.

Rissler, <i>loc. cit.</i>	Female; 21 years; 8 days.	Epidemic (exposure to cold).	First of right, then of left leg; then of arms and trunk; dysphonia, asphyxia.	Normal; no pain.	Normal.	Absent.	Not mentioned.	T, 100.5°.	Spleen soft; changes in cord similar to previous case; medulla not examined.
Rissler, <i>loc. cit.</i>	Child; 5 months; 6 days.	Epidemic.	Paralysis of all four extremities; dysphagia, dysphonia, asphyxia.	Test impossible.	Normal.	Lost.	Not tried.	Not given.	Spleen soft; changes in cord same as in other cases; lesion in vagus.
Dauber, <i>Deutsch. Zeitsch. f. Neurol.</i> , 1893, xiv, p. 200.	Boy; 8 1/2 years; 5 days.	None.	Both legs and left arm; paresis of right arm; drooping of left labio-nasal fold; pupils react slowly; eyes turned upward and outward; dyspnea.	Not stated.	Not stated.	Absent.	Not stated.	P. rapid, T, 100 to 100.5°.	Medulla, intense hyperæmia around motor nuclei; circumvascular infiltration of round cells, which also form a free exudate in glia tissue; degeneration of nerve cells of nuclei, xii and x; central canal normal; changes chiefly in gray matter, though also in white; pia infiltrated. Spinal cord: similar changes in entire cord (cervical, lumbar); involvement of posterior horns as well as anterior; degeneration of columns of Clarke; lesion also seen occasionally in pyramidal tracts.
Goldscheider, <i>Zeit. für klin. Med.</i> , 1893, xxiii, p. 494.	Female; 24 years; 12 days.	None.	Legs; dyspnea, asphyxia.	Not mentioned.	Not mentioned.	Not mentioned.	Not mentioned.	Fever.	Degeneration of ganglion cells; vessels full; circumvascular infiltration; changes chiefly in anterior horns, though also in lateral columns; pia infiltrated, most markedly in lumbar region, also in cervical and dorsal; medulla, nerves, muscles not examined.
Redlich, <i>Wien. klin. Woch.</i> , 1894, No. 16, p. 287.	Child; 5 months; 10 days.	None.	Four extremities; dyspnea, dysphagia, dysphonia, asphyxia.	Slightly diminished sensibility.	Not given.	Lost.	No reaction.	Slight fever.	Polymyelitis of whole cord, extending into white matter; acute degeneration of ganglion cells; circumvascular infiltration of vessels; anterior horns most affected; areas of inflammation in medulla, especially around nuclei of 12th and 14th nerves. Nerves; some degeneration in brachial plexus.

(To be concluded.)

**A Sign of Hereditary Tuberculosis.**—The *Universal Medical Journal* for June contains an abstract of an article from the *Gazette hebdomadaire de médecine et de chirurgie* for March 19th, in which the writer states that M. Victor Hanot, from three cases observed by him, believes that stenosis of the pulmonary artery may be a manifestation of pulmonary tuberculosis. He asks whether stricture of the pulmonary artery might not be similar to the congenital aortic stenosis of chlorosis and an heteromorphous manifestation of tuberculosis. It would in that case, he says, not be presumptive of phthisis, but of immunity against phthisis.

## ACUTE OTITIS MEDIA.\*

By A. T. MUZZY, M. D.

ACUTE otitis media is a form of ear trouble that all have an interest in, and that should not be left entirely to the specialist. Perhaps none of us are so young as not to recall the time when sudden pain and inflammation in the ear received no further attention than an anodyne injection without examination, and a running ear was from principle left to follow its own will as best for the patient.

This affection is generally, whether primary or secondary, a well-marked condition, with a clear-cut beginning and course. The most frequent exciting cause is direct extension, either from the nasopharynx or the external canal. Some of the worst cases arise from the direct effect of cold, especially in elderly people; then come operations on the nasopharynx, particularly plugging for epistaxis, and nasal douching; and among rarer forms violent efforts at clearing the nostrils, and traumatism to the drums, as a "box" on the ear. Finally, I would mention as a prominent exciting cause inhaling of sea water while bathing. One Tuesday during the summer of 1889, at the New York Eye and Ear Infirmary, out of eleven new cases seven were acute otitis media from bathing the previous Saturday at the different resorts on the Long Island and New Jersey shores.

The predisposing causes are, first, inflammations of the nasopharynx, depressed conditions of the system, as in the fevers, the most frequent being scarlatina, the tuberculous diathesis, and pre-existing chronic otorrhea.

The usual course of an attack is a rapid onset of pain, more or less lancinating in character and sharply limited in area. Tinnitus or subjective noise in the ear soon arises, though not complained of on account of the existing pain. The younger the patient is the more likely is it to find fever; frequently in a young child this rapidly reaches vertigo and delirium. Inspection shows a red, swollen, exquisitely sensitive, throbbing drum. Deafness, though present and many times reaching a complete loss of the sense, is slower in development. After a time, varying from a few hours to two or three days, a more or less copious discharge takes place, on the appearance of which pain and swelling subside, and disappear frequently more rapidly than they came. There are some cases where the pain ceases without any discharge appearing; here the subsidence is gradual and slow. A second variety from the usual form is where the discharge appears without any preceding pain.

Inflammation may affect only a part of this very small space—the Eustachian canal, the canal and lower

portion, the vault or attic alone, or the inner surface of the middle ear.

There are a few conditions where this trouble, usually so clear, is liable to be mistaken for other processes. In a child, pain in the head, vertigo, delirium, fever, without inspection of the ear, might be mistaken for meningitis. But meningitis rarely sets in with such suddenness, such acute pain, such high fever; the pulse, and the vomiting if present, are not meningitic. Besides, neither the respiration nor the pupils or oculomotors are affected. Still, it will be well to remember that even an acute otitis media may bring on meningitis. In another condition acute otitis media may be—very frequently is—insidious, and that is where it is a complication of or secondary to bad cases of scarlet or typhoid fever. The patient gets restless, clutches at the ear, or buries the head in the bedclothes; a more or less sudden increase in the delirium, if already existing, or a delirium changing into coma, leads the observant physician to examine. And inspection of the ear shows redness, swelling, or discharge.

The result of an attack in active healthy persons is good and speedy, even though the seizure has been severe. But in strumous, unhealthy children subacute attacks, even, will require great patience and care to bring them out to a successful issue. This is especially true where the cases are complications of or closely secondary to the exhaustive fevers.

In treatment the first point is the pain. The more acute, however severe, the more sure will be the benefit from leeching, whether with the natural or artificial. To myself the artificial is far preferable; it is applied more speedily, it draws more steadily, creates more surface irritation, and is clean comparatively. Next to leeching comes heat—dry, moist, or liquid—hot water injected slowly and gently; hot meal, sand, or the Japanese hot box. Try the dry form of heat first. The employment of laudanum or other anodynes is useless and wastes precious time. Cathartics as derivatives, mercurials or salines, should be used early. Many of the best authorities speak of the puncture of the drum. That close watch should be kept, and this incision be made as early as the inflammation bulges the membrane in a definite portion, is well. It is a very valuable procedure. But if your patient is a sensitive child, with ear exquisitely tender and with much swelling of the external canal, it will be far safer and as effective to rely on leeches, heat, and cathartics than to try a stab in the dark. Don't forget the proximity of the internal carotid, and that it has been punctured. If in an adult you have punctured the drum, and matter only presents without extruding, inflation by the Politzer apparatus will assist to remove the pus.

After-treatment—that is, after disappearance of pain—consists in cleansing and use of astringents, pure fifteen-volume peroxide, followed by a swab of alcohol, and dusting or even a heavy coating of powdered borax,

\* Read before the Society of the Alumni of the City (Charity) Hospital, May 6, 1896.

but never a filling of the canal, as was recently much in vogue.

Before closing it needs to be stated that the inflammatory process may at any time spread to the mastoid cells. This is heralded by an increase in the severity of all the symptoms; the pain that had gone down or disappeared reasserts itself and spreads over the side of the head, and changes in character; the discharges may in a few hours disappear altogether; swelling over the mastoid takes place (though this is uncertain), but tenderness to light tapping or firm, deep pressure by the finger is a safe but not infallible guide to indicate the presence of inflammation of the mastoid cells.

### SUDDEN DEATH AND THE CORONER.\*

By JOHN B. HUBER, A. M. M. D.,  
EX-CORONER'S PHYSICIAN OF NEW YORK CITY.

AN indispensable adjunct of government is an officer charged with the duty of investigating deaths from other than natural causes. Whichever system is in vogue, the objects sought after and the lines worked upon are practically the same.

In New York this duty is assumed by the coroner, who, except in instances to be mentioned later, has a jury summoned, before whom he places all the facts in a given case. These gentlemen then determine, first, the cause of death; and, second, if any one has caused the death, the person or persons responsible.

If the coroner's jury find evidences of guilt, the matter is laid before the grand jury by the district attorney, and if that body finds a "true bill," there follows a prosecution in the criminal courts; or, if the death has been accidental, a suit for damages may be brought in the civil courts.

The coroner appoints a physician, who is called the "coroner's physician." The duty of this officer is to view the dead body, to make an autopsy if necessary, and to state his opinion as to the cause of death, which opinion is based upon the post-mortem examination and the history of the case.

The coroner is empowered to have witnesses attend the inquest. The witness will testify either as to facts, or he may give expert testimony. In the latter case a physician can not be called upon to testify except by pre-engagement and for compensation.

In testifying, the physician will address the jury, who are laymen. He should therefore state facts precisely and in simple terms. He should answer the questions put to him by the coroner or the counsel deliberately, and should require to have a question repeated if it be not entirely comprehended. And technical expressions, if it is necessary to use them, should be followed by translation into popular language.

The coroner may inquire whether death was due to accident, suicide, or homicide; and if there were traumas, when, where, and how, by what means, and by whom they were inflicted.

Accurate descriptions may be required of wounds, contusions, fractures, burns, or whatever the nature of the injury may be in a given case, and the medical history may have to be detailed. Embarrassment on the witness stand may be avoided if a record of the case be kept, to which the physician may refer while testifying.

It is important for the self-protection of the surgeon to record the character of any operation performed for the relief of an injury where the prognosis is grave. The condition of the patient before the operation, especially as to inflammation and possible septic processes, the character and the details of the operation performed, and its sequelæ should be described.

The operation should not be decided upon except after consultation, especially in homicide cases, for the physician has upon his shoulders not only a medical but also a medico-legal responsibility. There should be strict antiseptics, and as perfect surgical technique as possible, and the physician should be able to state clearly the necessity for the steps taken, and, in the event of death, to what extent, if any, the operation may have been contributory. The following is an illustration on this subject:

A woman who had been shot under the left eye by her husband was immediately afterward brought to one of our hospitals. On her entrance a piece of the bullet was found in the substance of the muscular tissue in the temporal region. The surgeon, with the hope of locating the remainder of the bullet, used a probe, which entered the cranium. On the third day after the injury it was decided to trephine, the diagnosis of extensive intracranial hæmorrhage having been made. On the fourth day the patient died.

The autopsy revealed fractures of the left malar and temporal bones and laceration of the muscles in the temporal region. Within the cranium there was found a subdural lining of coagulated blood, which had formed the circumference of a clot of about the size of a goose's egg, and which had been removed in the operation on the third day. There was laceration of the brain and an inflammation of the pia in the exudative stage, the meningitis having been especially marked about the site of the injury. A fragment of the bullet was found in the substance of the left temporo-sphenoidal lobe. The cause of death was stated to be meningitis following pistol-shot wound in the head.

At the inquest the attorney for the defense sought to attribute the death to the surgical means employed, maintaining, in the first place, that infection may have followed, and have been caused by the operation; and in the second place that the meningitis may have been due to the introduction of the probe, which may have been septic. Upon the former point it was shown that

\* Read before the Society of the Alumni of the City (Charity) Hospital, May 6, 1896.

the meningitis in the effusion stage could not have developed in the twenty-four hours intervening between the operation and the death. The latter point was argued at length, with little hope of a satisfactory conclusion, until it was stated that the death must inevitably have followed the extensive intracranial hæmorrhage and the laceration of the brain. The finding of the jury was in accordance with this statement.

What steps should the attending physician take in "coroner's cases"?

The law of the State of New York requires that the coroner shall take action "whenever any person has been slain or has suddenly died, or has been dangerously wounded, or has been found dead under such circumstances as to require an inquisition." The coroner should be notified whenever any person has been dangerously wounded, in order that an ante-mortem statement may be taken.

The meaning of the phrase "sudden death" extends to cases where death has followed an illness of less than twenty-four hours, and where a regular physician has not been in attendance beyond that length of time. In most cases the course is obvious. It is the duty of every citizen to report a case of violent or suspicious death; this may be done by the attending physician, the members of the deceased's family, or any interested person. The coroner's office is open throughout the twenty-four hours to receive information either by telephone or by letter, or the police may be notified, who will in turn notify the coroner. It is in cases where the unofficial mind does not see the necessity for investigation that trouble is apt to ensue, as where there is a fracture of the femur in the aged, or erysipelas following a quite innocently inflicted wound.

The physician may dread being called away from his own very important work to attend court. The family of the deceased may picture to themselves the coming of public officers to the house, the appearance of a jury, an autopsy against their wishes, subpoenas to appear at the inquest, and a ventilation of private concerns in the court room.

It may not occur to the attending physician that an inquest would be required. He may, instead of having the coroner notified, send a certificate to the health board, only to have it forwarded to the coroner's office for further action. The certificate thus made out may have been sent to the health board a few hours before the funeral, so that that ceremony may have to be delayed or postponed until after the coroner's investigation. Or some suspicious person may inquire why the coroner had not been notified at once, and the suspicion may spread in the familiar way. Thus, in an altogether innocent matter, much hardship may be added to that which the family already suffers.

The law of the State of New York has, so far as the city of New York is concerned, wisely provided for all such cases. It states that—

"When, in the city and county of New York, any person shall die from criminal violence, or by a casualty or suddenly when in apparent health, or when untended by a physician, or in prison, or in any suspicious or unusual manner, the coroner shall subpoena a properly qualified physician, who shall view the body of such deceased person externally, or make an autopsy thereon, as may be required. The testimony of such physician, and that of any other witnesses that the coroner may find necessary, shall constitute an inquest."

The practice in the coroner's office is quite in conformity with this law. The coroner's physician assigned to the case will visit the house, view the body, and receive statements. It will not be justifiable to make an autopsy if the other evidence that the death was a natural one is conclusive. The coroner's physician will submit the results of his investigation to the coroner, and, if the report is satisfactory, a certificate is granted.

In such cases the attending physician's statement will be more than ordinarily valuable, because it will be that of a medical man. If he will soon after the death mail to the coroner's office, or leave at the house of the deceased, a letter addressed to the coroner, giving in a few words the medical history of the case, and his opinion whether the death was due to natural causes, he will help greatly to simplify matters, and the coroner's physician will be sincerely thankful for his assistance.

Such a statement will in appropriate cases obviate the issuing of a subpoena for the physician's appearance at the coroner's office. The hospitals of the city are provided by the coroner's office with printed blanks, on which the required statements may be written.

The following are some examples of causes of death given in certificates sent to the health board which have been in time sent to the coroner's office:

Asthenia de senectute.

Contributing cause, fracture of femur.

The fracture was probably sustained in falling out of bed or by slipping on the street. But some one may have struck or pushed the deceased, thus becoming more or less responsible for the death. In any event, whenever the result of an accident has contributed, no matter how remotely, to the death, the case is one for investigation.

Meningitis.

Erysipelas.

Peritonitis.

Gastro-enteritis.

It should have been stated whether the disease was idiopathic or the result of a fall, a wound, a blow, or the ingestion of poison.

Convulsions.

Heart failure.

Edema of lungs.

Such are immediate causes of death. The underlying, essential causes should have been given.

The coroner's office is from time to time charged with the unpleasant duty of investigating deaths following criminal abortion.

Any physician may be called upon to see a patient suffering from the more or less disastrous results of an attempted criminal operation. If he has the slightest ground for suspicion, the physician would do well in such cases not to make any examination, digital or other, except in the presence of a colleague. Nor should he induce an abortion, however legitimate the object, without consultation and medical assistance. Upon this subject I should like to cite the following case:

A poor girl in this city became pregnant. There was an abortion at about the fourth month, followed by septicæmia and death. The autopsy showed the cause of death to have been puerperal septicæmia. Decomposed placental tissue was found in the uterus, but there was no mark of instrumental violence.

Shortly before her death the girl made an ante-mortem statement, in which she named a physician whom she accused of having operated upon her. The accused physician declared that, although the girl had called at his office, he had seen her but once, and that, on finding her errand to be to importune him to induce an abortion, he had absolutely refused to treat her, that he had not prescribed for her, and that he had not examined her either by digital examination or by the use of instruments, or in any way whatever.

However, he was arrested and imprisoned; he was for a long time under bonds; his name was exploited in the public press in connection with the case; and he had to pay heavily, without hope of remedy, for the services of counsel, not to speak of loss of time, the injury to his practice, and the great mental strain to which he must have been put.

Finally, after a number of weeks, his case came up before the grand jury, and that body, in refusing to indict him, placed the guarantee of the law upon the truth of his statement, and established his innocence.

152 WEST FORTY-EIGHTH STREET.

## A PLEA FOR PHYSIOLOGY OF THE SEXUAL SYSTEM.

By A. C. McCLANAHAN, M. D.,  
RED LODGE, MONTANA.

If the importance of a subject were to be estimated by the frequency with which we find a knowledge of that subject useful, the ordinary general practitioner, whose duties range all through the domain of medicine and surgery, would unhesitatingly say that it is more important to know when and how to extract a tooth than it is to be able to perform a vaginal hysterectomy.

Whether this standard of importance is correct or not, there are many little things that merit more attention than they receive in standard medical literature. There are many conditions which require no treatment, and we may call these conditions "little things," but whenever an ailment really is so trivial that it requires no treatment, it would be gratifying to the physician to

know this to be true, and to know why it is true. The things which we should not do are at least as numerous as those which we should do. A little knowledge of these things would be useful, and might enable us to convince a patient of the needlessness of treatment without losing his subsequent patronage. It might enable us to charge an honest fee for relieving the patient's anxiety, instead of robbing him, as we do whenever we charge for a worthless placebo. A placebo is a confession either that the physician has not made a diagnosis, or that he does not know how to treat what he has diagnosed. If he knew, he would prescribe medicine that would in itself have the desired effect. If he knew nothing to be the matter, he would, it is to be hoped, prescribe nothing, and thus avoid confirming the patient in his erroneous opinion; for such confirmation of such erroneous opinions comes very near the border line of quackery, if, indeed, it does not pass beyond it.

Among the "little things" that have received least attention, in the eager rush of modern doctors to distinguish themselves by unsexing some woman, or by cutting off some one's appendix vermiciformis, I should like to mention sexual physiology. Whether this subject is really little or not I do not know, but it has received little enough attention. Sexual pathology has filled volumes without number, some of which have been written for the profession, and some for the laity; it also constitutes a large proportion of the reading matter in modern newspapers; but the consideration of sexual physiology is limited to a few perfunctory remarks by a very few writers on general physiology, or by some writers on the treatment of sexual diseases. At least, if there are any books in which this subject is satisfactorily treated, their names do not appear in the catalogues of the principal booksellers of this country.

Now, because we do not need to treat every sexual phenomenon which our patients present, it does not follow that we do not need to know anything about these phenomena. It is not quite self-evident that, while we need countless volumes to tell us about abnormal sexual functions, we can learn all about normal sexual functions by intuition. So great is the dearth of literature on one side of this subject, in comparison with its richness on the other, that the mere mention of sexual functions suggests something abnormal. So profound is the silence upon one side of this subject that most men and women, upon first learning that they have sexual feelings, imagine that they are either abnormal or unclear. Most of them keep what they imagine to be their awful secret to themselves till the lapse of time teaches them that, whether they are different from other people or not, their capacity for usefulness has not been impaired, their ideas of right and wrong are not less exalted than they were before, and life is still worth the living; but, in the mean time, they have endured needless suffering. On the other hand, many of them, impelled by an awful fear, as vague as it is awful, seek the advice of some

physician or some quack. If they consult the latter, he robs them systematically. If they consult the former, he usually acts on the assumption that any one who feels miserable enough to consult a physician is suffering from something that is not normal. This easy assumption makes it unnecessary to perform the difficult task of determining, by a careful consideration of the phenomena presented by the patient, whether these phenomena are normal or not. The physician accordingly classifies the patient's condition as one of sexual neurasthenia or hypochondriasis, passes a sound, prescribes some drug for some vague purpose, or orders a placebo for no purpose at all—except to deceive the patient, while Nature does the work and the doctor gets the credit. Of course, as a rule, the patient recovers—from what? Not, as a rule, from sexual neurasthenia or sexual hypochondriasis. If a young man or woman experiences a series of new and strange feelings concerning which he or she has been kept in the densest ignorance; concerning which all the world preserves an awful silence; concerning which no one ever speaks except in a guilty whisper; and if, in addition to this, this boy or girl has read in the advertising columns of respectable papers what the awful consequences are of every sexual feeling or lack of sexual feeling—normal, abnormal, or otherwise—and then, if this boy or girl, man or woman feels sufficient uneasiness about his or her condition to consult a physician, that physician has no scientific right to classify this case as one of sexual neurasthenia, hypochondriasis, or any other disease; nor has he, in my opinion, any moral right to treat it. Such a case is simply one of fear and anxiety; and, under the circumstances, both fear and anxiety are perfectly physiological mental phenomena. The physiological effect of fear and anxiety on the bodily functions is depression, and the effect ceases with the cessation of the cause, unless the latter has been excessive or very protracted. Even after excessive and protracted depressing mental emotions, the effects, as a rule, speedily disappear after the cause ceases to act, in obedience to Nature's laws, and without any aid from doctors. Such a patient as I have described would usually get well with treatment, without treatment, or in spite of treatment. What right have we to regard pain, either physical or mental, as necessarily abnormal? If I cut my finger, pain will be the physiological result. I have a right to relieve such pain, but I have no scientific right to regard it as abnormal, or to assume that Nature would not, in most cases, relieve it without any aid from me. Perhaps the pains of most men's lives outweigh the pleasures. Look for a moment at the bumps and bruises and burns, the tears, the trials, and the tyrannies of childhood; at the jealous passions and unrequited loves of youth; at the exhausting labors and consuming anxieties of manhood; at the dreary disappointment and the cheerless loneliness of old age; and at the agony of death, through which we all must pass. Are not these pains perfectly natural and physiological? Shall we lend another ele-

ment of terror to them by calling them abnormal? All along the path of life we feel the pains of pinching cold, of withering heat, of hunger's pangs, of scorching thirst, and deadly weariness; of base ingratitude and causeless malice; of fear, regret, remorse; of grief, anxiety, and disappointment.

The saddest thing in life is life itself, but can we make it less sad by calling it abnormal? Shall we pick out each separate pain, regard it a disease, outline the course of medical treatment that shall be followed, and, in general, create the impression that it could not be recovered from without our advice and medicines? Such a course might increase our profits, but any mental pain, at least, is enormously increased by the belief that it is abnormal, progressive, or that it does not tend to spontaneous recovery; and most sexual pains are mental, normal, non-progressive, and do tend to spontaneous recovery.

One patient consults me because he has morning erections; another because he does not have morning erections. Both felt perfectly well till it suddenly occurred to them that they were suffering from some sexual abnormality. If there is anything that will send the cold shudder of despair along a man's spinal column, it is the conviction that he is a sexual invalid; and it is perfectly natural that this should be so, not because the sexual functions possess any naturally mysterious peculiarity, but because these functions have been shrouded in so much artificial mystery; because such dense and helpless ignorance on the subject prevails in all classes of mankind; and because, by polite society's deathly silence on this subject, the world has succeeded in convincing itself that it is wicked to have any sexual functions, and deplorable not to have any.

If we made as great a mystery of our digestive functions as we do of our sexual functions; never dared to speak of eating or of food prepared for eating; wrote novels filled with descriptions of the pleasures and pains of pursuing and possessing uncooked food, but never dared to allude to the ultimate intention of our heroes to eat that food; and if the intrepid novelist who did dare, even in the vaguest and most indirectly suggestive way, to speak of that intention, were branded as an infamous writer of immoral books—the misery of mankind would be transferred from the sexual organs to the stomach. Great God! the Creator of all Nature, is it a crime to possess a penis or a vagina? Or, possessing one, is it a crime to feel the natural desire to put it to its intended uses? Or, being subjected to the ordinary vicissitudes of life, being occupied with other interests, shall we wear the brand of physical or mental inferiority if from time to time all such desires are absent?

More suffering is caused by ignorance than by all other causes.

Now, let us return to the patients who are troubled by the presence or absence of morning erections. I tell them both that their condition is perfectly natural; and

tell each that, sooner or later, he will experience the exact opposite of his present condition; that this new condition will be equally natural, for the reason that the uniformity of nature requires that the same cause shall produce different effects under different circumstances, and circumstances are constantly changing; that all that he is suffering from is mental distress; that he would, in due time, have recovered from this without any doctor's advice; but that, if I have shortened the period of his suffering, and enabled him to escape such suffering in the future, I am entitled to my usual fee.

Of course, I do not mean by this that there are no diseases of the genital organs. Gonorrhœa is a very real disease. Cases of neurasthenia or hypochondriasis undoubtedly exist in which the sexual element is a prominent one, and this element may figure as cause or as effect. Impotence is occasionally a reality. Real impotence, however, is a less calamity than the loss of one's teeth, and it remains true that most people who are seriously distressed on account of their genital functions are not the victims of any disease, and do not require treatment.

I must admit that, after receiving this information from me, such a patient usually consults some other physician; and, under the influence of the delusion that distance lends value to advice as it lends enchantment to a view, he will look up the address of some medical college of which he never heard before; write to "The Dean," "The President," or "The Secretary"; cheerfully put himself in the care of a man three thousand miles away, whom he never saw and never will see, of whom he never heard, and whose very existence is a matter of the merest inference; and then he will proceed to get well. The dean, the president, or the secretary of a medical college is of necessity an expert in the treatment of sexual debility. O Credulity, thy name is Man!

I have the greatest faith in drugs, nursing, surgical procedures, regulation of diet, and regulation of habits when these things are necessary. They are seldom necessary in the class of cases under consideration; and when a patient is suffering from ignorance, pure and simple, is it not best for him, and most creditable to the doctor, to supply information instead of drugs? The patient may not be satisfied with the assurances of one physician, but, if all respectable physicians would kindly but firmly tell him the honest truth, although he might drift from one to another, he would finally have increased respect for all. He would finally believe the truth, and his suffering would cease.

Most physicians are skillful, honest, self-sacrificing, and sympathetic in the treatment of almost all kinds of ailments except functional disorders of the sexual system. With reference to these troubles the profession may, for practical purposes, be divided into two classes: in the one class are those physicians who share the delusions of their patients, confound the pains of ignorance with the pangs of disease, and honestly regard any varia-

tion from an imaginary standard of sexual health as a mysterious horror which can not be escaped from without professional aid; in the other class are those physicians who regard such ailments as a legitimate object of mirth and ridicule among professional acquaintances, but who generally consent to treat these imaginary ailments with very real drugs, being actuated, it is to be hoped, by doubt rather than by dishonesty.

There is room in the world for more literature on the subject of normal sexual phenomena—literature that shall be written in the spirit of science and with the pen of common sense. My only object is to point out the want, in the hope that some one who is able will supply it. What now passes for sexual physiology is, as a matter of fact, sexual theology. Away back in the dismal darkness of Europe's age of faith, when "the exquisitely tempered steel of Greek philosophy had been shattered by the leaden mace of bigotry," patristicism elaborated a system of astronomy, of geography, of chronology, of chemistry, of mechanics, and, among the rest, a system of sexual hygiene and physiology. Science has dissolved the crystal vault of heaven; removed the petty limits of theology from space, and stretched the universe to infinity; unbound the earth, and given to it a double motion; placed the American continent where hell once was; exchanged six thousand years for eternity; replaced ghosts with gases; given to us gravitation and the laws of motion; and, with the exception of a few anatomical discoveries, left our sexual organs and functions where they were fifteen hundred years ago—in unspeakable disgrace. They are still under the ban of ancient theology. If any one doubts this, let him read the best that modern scholarship has to offer on the subject of the reproductive organs, and he will find that it consists largely of dreary quotations from what ancient theologians had to say on the subject—the same theologians who taught that the earth was flat, and that a telescope was an embodied crime. What we now regard as physiological with reference to these organs is merely what the Church, in the night of her superstition, taught to be right. The spirit of antiquity pervades the whole subject. The absolute annihilation of all sexual acts, words, and thoughts is still regarded as essential to the highest type of purity. While we have two separate words for continence and chastity, the idea conveyed by these two words is, to most modern minds, one and the same. A woman who would confess to feeling sexual desire would lose her reputation for virtue; and because, under these circumstances, she will not often confess to it, we set it down in our text-books that an ideal mother has no sexual feeling, and only submits to her husband's embraces to gratify his passions, and to keep him from seeking gratification elsewhere. Of course, the husband who accepts such sacrifices is regarded as an unutterable beast. Pregnancy still bears the brand of uncleanness, and we exchange sly looks and vulgar winks as it passes by. Infanticide is the result, not so much of parental selfishness as of

the unwritten social odium of maternity. A thrill of sexual delight, whether it be of slight or intense degree, whether it come in the silence of the night or in the glare of the ballroom, is to the modern physiologist, as to the ancient flagellant, an evidence of sexual derangement or of total depravity.

Of course, real social purity is not greater now than it was in the past, and the ideal purity of theology is as impossible as ever. Nature continues to assert herself; desire will be gratified; but, owing to our ideas on the subject, satisfaction is transformed into an infinite sense of degradation.

If modern sentiment on this subject is correct, it would still be just as well to have scientific proofs of it. It looks reasonable to believe that the criterion of the natural is Nature herself. Sexual physiology might be able to claim as her own a great many facts that have been appropriated by sexual pathology, and she might be able to teach us to contemplate an actually pathological sexual condition or act without becoming hysterical about it. She might, for example, teach us why the act of tickling the fauces to induce vomiting for the relief of an overdistended stomach is justifiable, while the act of tickling the genital organs to induce emission for the relief of overdistended seminal vesicles is damnable. She might tell us which of these two acts is the more unnatural, which the more disgusting, and which the more injurious. She might teach us why the salivary fluid, whose flow is excited by the sight of a cooked goose, is a matter concerning which we may speak, with the greatest gusto, to our dearest friends, while a drop of urethral mucus, whose flow is excited by the sight of Beauty's blushes, is a matter to send us to the specialist with shame in our faces and terror in our souls. She might teach us why the rectum—a nasty enough place under any circumstances—is rendered so unspeakably much more nasty by being put to the uses of a vagina. It is not at all probable that rectal masturbation would become universal even if our ideas of its hideousness were brought down to the limits of the facts. We do not eat dirt when we can help it, although we know we should not eternally forfeit our manhood if we did.

There are many other things that real science might tell us about the reproductive system and its functions. It is not my purpose to tell them, but merely to insist on the desirability of their being told by some one who possesses the necessary knowledge or the necessary means of acquiring it; and if it should turn out that scientific men have in the past thrown out a few common-sense truths on this subject, I would plead as my excuse that it can do no harm to take a look at these truths from time to time, and to add a few more to them.

**A Reception to Professor Klebs**, lately elected to the chair of pathology in the Rush Medical College, was given in Chicago by Dr. Fenton B. Turck, on Thursday evening, July 2d.

THE  
NEW YORK MEDICAL JOURNAL,  
*A Weekly Review of Medicine.*

FRANK P. FOSTER, M. D.

NEW YORK, SATURDAY, JULY 4, 1896.

THE ANTITOXINE REPORT OF THE AMERICAN  
PÆDIATRIC SOCIETY.

THE report of a committee of the American Pædiatric Society on the use of diphtheria antitoxine, a full abstract of which appears in this number, is a document of unusual importance. It is the first extended report not based on hospital cases which has yet appeared. The results of hospital treatment in some diseases are equal to those obtained in the best private practice; in other diseases they are notoriously bad. Measles, for example, is a most fatal disease in all infant hospitals. In February last, twelve young children sickened with measles in the New York Infant Hospital, and in eleven of them pneumonia of a very grave type developed. Would it be a fair inference to draw from such experience that over ninety per cent. of children who contract measles also suffer from pneumonia, with a correspondingly high mortality rate? Diphtheria belongs to the same category of diseases. As in measles, pneumonia and other complications are of far more frequent occurrence in hospitals than in private practice. Hospitalism is the cause of death of many children upon whose death certificate diphtheria is written.

The feeling has been growing in the profession that the only decisive test of the antitoxine treatment was to be derived from private practice, where the patients are in reasonably good condition at the outset and are fairly free from conditions which tend strongly to render any treatment ineffective. Such a test the American Pædiatric Society has attempted to make. The character of the committee having the investigation in charge offers ample assurance that the work has been done fairly and honestly. Such assurance is confirmed in reading the report, which at once impresses one with the air of judicial fairness which pervades it. No fatal case was excluded even when the cause of death was doubtful. On the other hand, every doubtful case which ended in recovery was excluded. Some cases of mild diphtheria were thus, no doubt, not included, and the death-rates reported

were correspondingly increased. After giving the statistics for all cases, the committee acted quite within its right in excluding those of patients moribund at the time of receiving the injections. The facts that some patients are not seen early by the physician and that in some cases diphtheria runs a rapid and malignant course from the outset is a misfortune, but is not a valid argument against the treatment.

The number of cases—almost six thousand—is certainly large enough to warrant some positive conclusions. Their distribution in the practice of six hundred and thirteen physicians, from a hundred and fourteen cities and towns, in seventeen different States, adds material weight to the report. The results can not be due to local influences. The length of time during which they were observed also precludes the belief that they occurred during a single epidemic.

Certain points with regard to treatment with reasonable certainty by this report; others are still left undecided. The importance of early injections is demonstrated with certainty. The mortality rate of 4.9 per cent. for the treatment begun on the first day, 7.4 on the second day, and 8.8 on the third day, suddenly rises to 20.7 on the fourth day and to 35.3 on the fifth day. The substantiating of Behring's original contention that if patients were injected on the first or second day the mortality would not be above five per cent. must prove of the utmost satisfaction to the practitioner. The infrequent occurrence of pneumonia, both in the fatal cases and in those of recovery, is another very important result elicited by the report. The effect of the serum in protecting the nerve cells and preventing paralysis is not clearly shown by the report, though the results seem to be slightly in favor of the treatment. Such discrepancy exists in the experience of different observers regarding the frequency of paralytic sequelæ that more extended observations will be required to settle this point. It is clear that the nerve elements are extremely susceptible to the diphtheria toxine, and it is probable that antitoxine must be injected early to exert any protective power over them. As regards nephritis, the report adds little to our knowledge regarding the effect of the serum either to cause or to prevent it.

The crucial test of the treatment lies in its effect upon laryngeal diphtheria, the most fatal of all forms of the disease. The diagnosis and the prognosis of this form are so definite and positive that conclusions regarding the results of treatment are far more reliable than in other and more uncertain varieties. The results

reported are definite and unequivocal. They can not be explained away. Of the 1,256 patients with croup, 563 recovered without operation. The death-rate in 533 cases of intubation was 25.9 per cent., including all hopeless cases. Deducting these, the rate was but 16.9 per cent. These results, compared with the best that have ever before been published, are startling. They are strengthened by individual reports from numerous reliable operators. Some of these include series of cases in which the intubations ranged from eight to twenty-seven, each series without the loss of a patient. The change from former results of less than ten per cent. of recoveries from croup without operation to the present record of over fifty per cent. is a marvelous one. Such results must afford unmingled satisfaction to the practitioner who has long found croup and diphtheria among the most stubborn and treacherous enemies he has been obliged to meet.

#### COHABITATION TRAUMATISM IN WOMEN.

Cases in which women meet with injury more or less notable in the act of copulation are by no means of rare mention in the annals of medicine. Obviously, the circumstances are commonly of such a character as to make the woman loath to call in the aid of a physician unless she is suffering great pain or losing a good deal of blood; so we may take it for granted that many instances of some seriousness are never reported, and consequently that the occurrence of greater traumatism than the mere rupture of the hymen is commoner than is generally supposed. How common it must be when one man is able to report three grave cases as having occurred in his own practice! In the *Gazette hebdomadaire de médecine et de chirurgie* for June 4th there is such a report, made to the Bordeaux Society of Gynecology, Obstetrics, and Pædiatry, by Dr. Maxime Chaleix.

Dr. Chaleix's first patient was twenty-two years old. She had been puny in her childhood and on two occasions had suffered with troublesome hemorrhage after the extraction of a tooth. Her history showed that the slightest bruise gave rise to an extensive ecchymosis. Her first coitus was accomplished with only moderate pain, but it produced an abundant and continued hemorrhage which did not yield to injections of cold water or to the application of compresses. Consequently, Dr. Chaleix was sent for in the morning, and he found that the loss of blood had been great

and that it was still going on. The patient was very weak, her skin was cold, her pulse was small, and she had ringing in the ears. The use of a very hot injection had only a transitory effect. An examination showed that the hymen, which was of the annular form and quite thin, had sustained two tears posteriorly, and from their point of junction blood was still flowing, as well as from the posterior wall of the vagina, where, quite behind the hymen, there was an erosion as large as a franc piece. Dr. Chaleix made rather energetic pressure on these points with iodoform gauze and gave a subcutaneous injection of Tanret's ergotine, whereupon the hæmorrhage stopped. The patient made a slow recovery and conjugal relations were resumed without further accident, but she had very violent post-partum hæmorrhage in her first confinement.

In the second case the patient was a very vigorous woman, twenty-four years old. In the first attempt at intercourse the loss of blood due to rupture of the hymen was slight, but the pain consequent on intromission was so great that the husband desisted. For two days some pain remained, and efforts at copulation were suspended, but there was no hæmorrhage. On the fourth night another attempt at coitus was made, but it at once caused extreme pain, together with a more abundant loss of blood than before. The woman got up and washed herself and then went to bed again. She felt that she was still bleeding a little, but disregarded the matter and went to sleep. At two o'clock in the morning she woke up and became aware that she had lost a great deal of blood. There was a great clot between her legs. It was then that Dr. Chaleix was called, and he found a continuous oozing from the vagina. A large hot injection seemed to stop the flow completely, and he left after prescribing an alcoholic restorative. At seven o'clock, however, he was called again in haste. The hæmorrhage had come on afresh after having ceased for some hours, and the patient was very pale and feeble. There was but a single laceration of the hymen, situated posteriorly, and the blood did not come from that, but from the vagina, which was narrow and showed several erosions of its posterior wall. It was tamponed as thoroughly as possible with iodoform gauze, and tonics were prescribed. On the following day the tampon was changed, and its employment was given up two days later. After that, the conjugal act was accomplished without any untoward result. In her confinement the woman had no

dystocia, although the vagina and vulva were still very narrow.

The third case was that of a bride, thirty years old. There had been very great resistance to intromission, but this had given way suddenly and the woman had uttered a loud cry and almost fainted. The husband had withdrawn his penis at once and seen that it was covered with blood. The wife was still bleeding copiously and suffering very acute pain. When Dr. Chaleix arrived, in about an hour and a half, he found a great quantity of blood in the bed and an oozing still going on from the vagina. It proceeded from several points, especially, in a little arterial jet, from the posterior part of the vulvo-vaginal ring. The hymen, pierced in its superior portion by a small orifice, appeared thick and tough. It had not been ruptured, but had been torn bodily from its insertion posteriorly and somewhat on the right side, so that it hung like a thick bloody flap over the posterior commissure of the vulva. A large hot injection was given, and the bleeding artery was treated by torsion. In addition, the posterior wall of the vagina and the bleeding flap of hymen were compressed with iodoform gauze. The hæmorrhage was thus promptly arrested, but it was several days before the bridal pair could resume their journey.

Severer injuries than those observed by Dr. Chaleix have been recorded, some of them consisting of ruptures of the perinæum and of the recto-vaginal septum, a few of which he cites. These injuries are not necessarily incurred on the first occasion of coitus. For example, Dr. Nicolaus Ostermayer (*Wiener medicinische Wochenschrift*, 1895, No. 39; *Deutsche Medizinisch-Zeitung*, June 4, 1896) relates the case of a woman, forty years old, who had intercourse with a man whom she had often been with before, but who was drunk on this occasion and approached her with extraordinary impetuosity, producing a crescentic transverse laceration of the posterior vault of the vagina nearly three inches long. In this instance, however, there were the remains of old inflammatory pelvic disease, which probably facilitated the laceration.

#### MINOR PARAGRAPHS.

##### A CONDEMNATION OF OLD COGNAC.

THE June number of the *Zeitschrift für Krankenpflege* mentions a recent communication to the Paris Academy of Medicine, by M. Daremberg, in which that gentleman is reported to have said that the dearer brands contained a particularly large amount of the so-

called furfural poisons—that the quantity of those substances, as well as of amyl alcohol, was far greater in them than in the brandies commonly sold in the liquor shops. Moreover, chemical analyses with regard to this matter were supported by toxicological experiments. In the first place, M. Daremberg had injected ten cubic centimetres into the auricular vein of each one of seven rabbits, using brandy containing thirty-five per cent. of alcohol bought at five different shops, and not one of the animals had died. On the other hand, he had injected into six rabbits the same amounts of old cognac, sold for sixty francs a bottle and containing thirty-eight per cent. of alcohol, and the animals had died on the spot. Two other rabbits injected with the same amounts of genuine cognac had speedily died also. From all this M. Daremberg drew the conclusion that old cognac was the most dangerous kind of brandy, and that physicians should be most strenuous in forbidding dyspeptic and nervous persons to use this extraordinarily poisonous drink. Brandy at twelve dollars a bottle ought to be pretty good, but, in view of M. Daremberg's experimental results, we can not avoid a doubt as to the quality of the cognac he made use of, in spite of its high price.

#### CRANIOTOMY, THE CÆSAREAN SECTION, AND INDUCED PREMATURE LABOR IN ONE WOMAN.

THE *Centralblatt für Gynäkologie* for June 30th cites the case, published in the *Orvosi hetilap*, of a woman who, having a generally contracted pelvis, was delivered of her first child by craniotomy when she was nineteen years old. A year later, she was delivered of a living child by the Cæsaean operation. Her third pregnancy terminated in abortion in the second month. Her fourth gestation was brought to a close in the thirty-fifth week by the artificial induction of labor, and she was delivered of a living child. The same intervention had been decided on in her fifth pregnancy, but labor came on spontaneously in the thirty-second week. At the time of the report the second, fourth, and fifth children were still living.

#### ITEMS.

**Infectious Diseases in New York.**—We are indebted to the Sanitary Bureau of the Health Department for the following statement of cases and deaths reported during the two weeks ending June 30, 1896:

DISEASES.	Week ending June 23.		Week ending June 30.	
	Cases.	Deaths.	Cases.	Deaths.
Typhoid fever.....	11	1	13	2
Scarlet fever.....	87	5	64	6
Cerebro spinal meningitis. . .	3	1	1	2
Measles.....	193	14	172	13
Diphtheria.....	218	18	222	33
Tuberculosis.....	260	112	177	119

**The Congressional Antivivisection Bill.**—On May 27th the American Surgical Association, in session in Detroit, unanimously passed the followed preambles and resolutions:

*Whereas*, The American Surgical Association has learned that the Committee on the District of Columbia in Congress has reported favorably a bill adverse to the practice of vivisection in the District of Columbia; and

*Whereas*, The passage of such a law will put an end to all the experimental work in the government laboratories at Washington, from which have emanated im-

portant and useful discoveries, especially as to the diseases of animals; and

*Whereas*, The passage of such a law by Congress will be used as a lever in promoting the enactment of similar laws in other parts of the country, and so do double harm. Therefore be it

*Resolved*, That, to our personal knowledge, the marvelous progress of surgery, especially within the last twenty-five years, is due very largely to experiments upon animals, and the continuance of such experiments is absolutely essential to the further progress of surgical science.

*Resolved*, That in our opinion the humanity of the entire profession is too well known and too constantly and conspicuously shown in their enormous charitable and kindly work to allow the assertion that they would countenance the practice of cruelty or the infliction of needless pain in such experiments to be believed by the American people or their representatives in Congress.

*Resolved*, That, by reason of this very humane sentiment, this association protests against the passage of the bill in question, because it will be a cause of untold cruelty to both man and animals by arresting to a great extent the beneficent progress of surgery.

*Resolved*, That a copy of these resolutions be sent to the President of the United States and to the Senate and House of Representatives.

[Signed] W. W. KEEN,  
H. L. BURRELL, } Committee.  
JOSEPH D. BENNET.

**Harvard University's Suit against the Harvard Medical College, of Chicago.**—The bill filed in this suit, which we mentioned last week, recites that Harvard University "has acquired a peculiar and exclusive right and title in and to the name Harvard, when used or proposed to be used as the name of a university, college, or professional school, and it ought not in equity and good conscience to be assumed by any other institution of learning, and if ever so assumed by any other institution must of necessity be so assumed and used in fraud of your orator's rights and for the purpose of assuming some of the credit and reputation properly belonging solely to your orator, and of injuring and endangering your orator pecuniarily and otherwise, and imposing upon and defrauding the public everywhere." The case will probably come into court next autumn.

**The Mississippi Valley Medical Association.**—The president, Dr. H. O. Walker, of Detroit; the chairman of the committee of arrangements, Dr. C. A. Wheaton, of St. Paul; and the secretary, Dr. H. W. Loeb, of St. Louis, have issued the following announcement:

"A meeting of the executive committee of the Mississippi Valley Medical Association was held at Atlanta on May 6th, and the following gentlemen were appointed to deliver addresses: Dr. H. N. Meyer, of Chicago, the address in medicine, and Dr. Horace H. Grant, of Louisville, the address in surgery. The indications are that the meeting to be held at St. Paul, on October 20th, 21st, 22d, and 23d, will be the largest and most successful in the history of the association. As all the railroads will offer reduced rates for the round trip, an opportunity will be given to visit St. Paul and Minnesota during the most delightful season of the year."

**Change of Address.**—Dr. B. Farquhar Curtis, to No. 7 East Forty-first Street, New York.

**Army Intelligence.**—*Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from June 21 to June 27, 1896:*

APPEL, DANIEL M., Major and Surgeon, is relieved from duty at Fort Porter, New York, and ordered to the new post near Little Rock, Arkansas, for duty.

APPEL, AARON H., Captain and Assistant Surgeon, is relieved from duty as examiner of recruits at Chicago, Ill., and ordered to Fort Porter, New York, for duty.

McCAW, WALTER D., Captain and Assistant Surgeon, Fort Ringgold, Tex., is granted leave of absence for one month, to take effect about the 5th proximo.

MAUS, LOUIS M., Major and Surgeon, Fort Sam Houston, Tex., is granted leave of absence for two months, to take effect on or about August 1, 1896.

**Naval Intelligence.**—*Changes in the Medical Corp, of the United States Navy for the Week ending June 27 1896:*

PALMER, S. B., Assistant Surgeon. Detached from the New York Laboratory, June 29th.

ROTHGANGER, GEORGE, Passed Assistant Surgeon. Detached from the Independence, July 15th, and ordered to the Oregon.

**Marine-Hospital Service.**—*Official List of the Changes of Stations and Duties of Medical Officers of the United States Marine-Hospital Service for the Twenty Days ending June 20, 1896:*

McINTOSH, W. P., Passed Assistant Surgeon. To proceed from Louisville, Ky., to Cincinnati, Ohio, to inspect unseviceable property; then to rejoin station. June 13, 1896.

PERRY, J. C., Passed Assistant Surgeon. Granted leave of absence for twenty days. June 20, 1896.

GARDNER, C. H., Assistant Surgeon. Order of May 27, 1896, directing him to report for examination revoked. June 5, 1896.

BLUE, RUPERT, Assistant Surgeon. To proceed from San Francisco, Cal., to Angel Island Quarantine Station for duty. June 18, 1896.

# **Society Meetings for the Coming Week :**

MONDAY, July 6th: New York Academy of Sciences (Section in Biology); German Medical Society of the City of New York; Morrisania Medical Society, New York (private); Brooklyn Anatomical and Surgical Society (private); Corning, N. Y., Academy of Medicine; Utica, N. Y., Medical Library Association; St. Albans, Vt., Medical Association; Providence, R. I., Medical Association; Hartford, Conn., Medical Society; Chicago Medical Society; Cleveland Medical Library Association.

TUESDAY, July 7th: Elmira, N. Y., Academy of Medicine; Ogdensburg, N. Y., Medical Association; Syracuse, N. Y., Academy of Medicine; Medical Society of the County of Broome, New York; Hudson (Jersey City) and Union (quarterly), N. J., County Medical Societies; Androscoggin, Me., County Medical Association (Lewiston); Chittenden, Vt., County Medical Society; Medical Society of the University of Maryland (Baltimore).

WEDNESDAY, July 8th: American Microscopical Society of the City of New York; Medical Society of the County of Albany, N. Y.; Tri-States Medical Association (Port Jervis); Franklin (quarterly—Greenfield), Hampshire (quarterly—Northampton), and Worcester (Worcester), Mass., District Medical

Societies; Kansas City Ophthalmological and Otolological Society.

THURSDAY, July 9th: Brooklyn Pathological Society; Medical Society of the County of Cayuga, N. Y.; South Boston, Mass., Medical Club (private).

FRIDAY, July 10th: German Medical Society of Brooklyn; Cleveland Medical Society; Medical Society of the Town of Saugerties, N. Y.

SATURDAY, July 11th: Worcester, Mass., North District Medical Society.

## **Births, Marriages, and Deaths.**

### *Born.*

GIRDNER.—In New York, on Thursday, June 25th, to Dr. and Mrs. John H. Girdner, a son.

### *Married.*

CASE—LIND.—In Columbus, Ohio, on Thursday, June 18th, Dr. Calvin Luther Case, of Pasadena, California, and Miss Hannah Frances Lind, of Central College, Ohio.

COATES—HESSE.—In Chicago, on Wednesday, June 24th, Dr. William E. Coates and Miss Bertha M. Hesse.

CUTLER—BABCOCK.—In Providence, Rhode Island, on Thursday, June 18th, Dr. George W. Cutler, of Columbia, Missouri, and Miss Emma H. Babcock.

HORTON—SCHRIEVER.—In New Orleans, on Wednesday, June 24th, Dr. Clarence L. Horton and Miss Cora Schriever.

JESSUP—BRITTON.—In Richmond, Staten Island, N. Y., on Tuesday, June 16th, Dr. George Pierson Jessup and Miss Marian Britton.

KIRCHNER—JONES.—In Clayville, N. Y., on Wednesday, June 24th, Mr. George Mitchell Kirchner and Miss Anna Margaret Jones, daughter of Dr. James E. Jones.

ROSE—DEVEREAUX.—In Syracuse, N. Y., on Wednesday, June 24th, Dr. Lewis W. Rose, of Rochester, N. Y., and Miss Imogene Devereaux.

SALLEY—CHAPPELL.—In Smithville, Virginia, on Wednesday, June 24th, Dr. P. M. Salley, of Orangeburgh, South Carolina, and Miss Eugenia Chappell.

TAYLOR—PIERCE.—In Forestville, N. Y., on Wednesday, June 24th, Dr. William G. Taylor, of Buffalo, and Miss Ophelia Frances Pierce.

VON TRESCROW—FOLWELL.—In New Orleans, on Wednesday, June 24th, Mr. Leo Helmuth von Tresckow and Miss Nina Folwell, daughter of Dr. Joseph N. Folwell.

WALKER—CASEBEERE.—In Cedar Rapids, Iowa, on Thursday, June 25th, Dr. Harry Lewis Walker and Miss Maude Elizabeth Casebeere.

### *Died.*

CHOATE.—In New York, on Sunday, June 28th, Dr. George C. Shattuck Choate, of Pleasantville, N. Y., aged seventy years.

COLLINS.—In Brookhaven, Mississippi, on Sunday, June 21st, Dr. Frederick E. Collins.

KENNY.—In Troy, N. Y., on Saturday, June 27th, Dr. Arthur G. Kenny, of West Troy.

SCOTT.—In New Orleans, on Thursday, June 25th, Dr. Joseph T. Scott, in the sixty-fourth year of his age.

TENNANT.—In Phenix, Rhode Island, on Tuesday, June 23d, Clara Greene Tennant, wife of Dr. George C. Tennant.

## Letters to the Editor.

### REFLEX EPILEPSY.

60 WEST FIFTH STREET, June 25, 1896.

To the Editor of the New York Medical Journal:

SIR: In a letter published in your issue of June 20, 1896, Dr. Ranney quotes the following abstracts from a paper of mine on The Medical and Surgical Treatment of Epilepsy (*New York Medical Journal*, June 6, 1896):

"1. Reflex epilepsy is so rare that the proportion of cases in which a reflex cause will be found is certainly not above one or two in a thousand.

"2. In chronic cases where the epilepsy has had its origin in a reflex cause, the convulsive habit has become so strong that removal of the reflex irritation will seldom alter the course of the disease.

"3. There are surprisingly few cases on record in which an operation of any kind whatever for the relief of so-called reflex causes has induced a cure of the epilepsy. I think authentic and trustworthy instances of the kind recorded in literature could easily be counted upon the fingers.

"Bearing these points in mind, the practitioner may perform his gynaecological operations, circumcise, carry out procedures on the nose, tamper with the eye muscles, or what not, but let him not be too sanguine of a successful issue. He will be fortunate indeed to meet with a single success."

I gather from the doctor's letter that his protest is directed more especially against the truths expressed in paragraphs 1 and 3. We will examine the two points which arouse the protest:

I state that *epilepsy from reflex causes is so rare that the proportion is certainly not above one or two in a thousand cases of epilepsy*. Let me amplify this. My own experience is embodied in the paper from which this extract is made, viz.: that "I do not remember to have seen, among several thousand cases, a single one of genuine reflex epilepsy." Consequently, it was in deference to other authorities that I made the proportion mentioned. Not to overburden this brief *résumé* with references, I cite just a few authorities close at hand:

Gowers, whose book (p. 733) is considered to be the best on nervous diseases in the two hemispheres, says: "It is extremely rare to meet with any evidence of a reflex cause [for epilepsy] in the system of the cerebro-spinal nerves, and in the few recorded cases there has been a manifest and strong predisposition in the brain."

Starr (*Familiar Forms of Nervous Disease*, p. 269): "I may add that, in my experience, reflex neuroses of an epileptiform type are exceedingly rare. I have records of six cases only in a series of 3,500 cases of nervous diseases."

Dana (*Text-book of Nervous Diseases*, p. 412): "The importance of reflex irritations has been much overestimated."

Sachs (*Nervous Diseases of Children*, pp. 69-71) does not even mention under Causes of Epilepsy reflexes of any kind, though in a footnote he says concerning reflex epilepsy described as due to peripheral injuries (hand or foot): "A permanent epilepsy is rarely established in this

way." Concerning eye conditions, he says they "may cause single attacks; but they are surely not the cause of the epilepsy."

When I said that the proportion of reflex epilepsies was certainly not above one or two in a thousand cases, I referred to all reflex causes. If I had referred to eye conditions only, I should have said possibly one in ten thousand, if they exist at all as causes of epilepsy.

The second point protested against is the sentence relating to cure of reflex epilepsies: "*I think authentic and trustworthy instances of the kind recorded in literature could easily be counted upon the fingers.*"

Concerning this my censor says:

"Does Dr. Peterson think that no one is 'authentic or trustworthy' who has ever reported cures of epilepsy either by circumcision, the removal of diseased ovaries, the extraction of teeth, the removal of scars, or 'tampering with the eye muscles'?"

"Does he hope to arraign the credibility, honesty, and skill of hundreds of medical men of repute when he says that all 'authentic and trustworthy' cases of the cure of epilepsy by removal of reflex causes can be counted on his fingers?"

In answer I would say that in making such a count of authentic and trustworthy instances, I should exclude the following classes of cases:

1. Cases reported cured too soon after operation.
2. Cases in which the fact of the existence of genuine epilepsy is not well established.
3. Cases reported by writers misled by the personal equation in their judgment of facts.

There are other reasons that doubtless suggest themselves to those familiar with the subject.

The doctor asks me if I "hope to arraign the credibility, honesty, and skill of hundreds of medical men of repute." Will he kindly name one hundred of these hundreds, or fifty, or ten? Will he name five? Indeed, I should shrink from arraigning the credibility, honesty, and skill of any medical man of repute.

I believe that all neurologists coincide in the views expressed here, and that most oculists (with the exception of Dr. Ranney and a few others) are of the opinion that muscular insufficiencies are of no importance in the aetiology of epilepsy.

It is easy to see where the doctor's conclusions from his own experiments are faulty. It is a species of mind-blindness. Conceding the accuracy of his reports of twenty-six cases treated by tenotomies (and in one of his papers he openly boasts of having committed one thousand tenotomies in ten years), it is quite clear that any improvement he may have had in the cases reported is due to but two factors:

1. The withdrawing of the bromides in cases for years under bromide treatment.

2. A species of suggestion and counter-irritation induced by numerous operations on one of the most delicate of sensory organs.

It is a wrong interpretation of these two factors which has led him into conclusions that can not be sustained. It is a fact which has not as yet received sufficient attention, that in cases of chronic epilepsy long treated with bromides relief from attacks for considerable periods of time follows diminution or cutting off of the bromides. This is the experience in hundreds of cases at Bielefeld, and is the experience of physicians at Craig Colony since the opening of that institution. It is the exception to have ill effects follow withdrawal of bromides; but these exceptional cases have originated a somewhat prevalent

but erroneous belief that the withdrawal of bromides tends to increase the frequency of attacks.

Now, counter-irritation is an old and well-tried remedial agent in epilepsy. It used to be employed frequently in the shape of setons and blisters to the neck, blistering of the scalp, and the like. It is often beneficial to a remarkable degree. How much more effectual, especially upon the psychic condition, must be the application of a knife to the eye!

The doctor therefore rightly says that "at least ninety per cent. of chronic epileptics have been better without bromides," but his addition of the phrase "after a satisfactory correction of their eye defects" shows to what extent illogical reasoning may lead.

Then he goes further and makes the statement that about twenty per cent. of his cases have apparently been cured. Having committed a thousand tenotomies in ten years, he reports twenty-six cases of epilepsy only, and states that twenty per cent. of these are cured. The statement is not borne out by his own reports of these cases.

If twenty or even ten per cent. of these twenty-six cases have been cured, which ones are they?

That the cutting off of bromide treatment and the form of counter-irritation employed have been beneficial is doubtless true.

But is not this form of suggestion and counter-irritation rather too expensive for most patients?

FREDERICK PETERSON.

#### THE ANTITOXINE TREATMENT OF DIPHTHERIA.

285 LOOMIS ST., CHICAGO, June 24, 1896.

To the Editor of the *New York Medical Journal*:

SIR: In view of the discussion now going on in the *Journal*, of which I have been three years a reader and subscriber, I frankly indorse the views of Dr. Winters in regard to antitoxine in diphtheria. Of one case I must write in terms of strong condemnation. The facts are as follows: I was called to see a boy, eight years old, pulse rapid, temperature 105°, and the laryngeal appearance quasi-diphtheritic. I began the ordinary treatment, in which quinine, carbolic acid, and iron formed chief parts. The result next morning was very satisfactory; all alarming symptoms were decidedly not much in evidence. Some time in the evening of this *better* day our antitoxine friends raided the house and began their injections *à l'outrance*. They did not inform me, I need scarcely say; but, like birds of evil omen, they swooped down on a defenseless widow and daughters, and injected mightily, nay, as the sequel proved, mortally. Need I express an opinion after this, on the discovery, or at least its manipulators? W. J. NOLAN, M. D.

### Proceedings of Societies.

#### SOCIETY OF THE ALUMNI OF THE CITY (CHARITY) HOSPITAL.

Meeting of May 6, 1896.

The President, Dr. R. C. NEWTON, in the Chair.

**Nævus Verrucosus.**—Dr. GEORGE T. JACKSON presented a picture of a case of *nævus verrucosus* occurring in a mulatto woman. The disease had begun in

childhood, and had gradually grown worse until she had reached the twenty-first or twenty-second year. It had been a benign growth, and also a deformity. It could be removed by curetting, by the scissors, or by electrolysis. This growth was remarkable for its distribution and size, occupying the upper fourth of the right side of the body, and extending down upon the right arm to below the elbow.

Dr. A. RUPP asked whether it was considered neurotic or microbic by dermatologists.

Dr. JACKSON stated that it was probably neurotic. It belonged to the same class as the ordinary pigmentary mole. A part of the case pictured was pigmentary, a part fibrous, and a part like papillomatous growths. It was only on one side. There was also a patch over the umbilicus on the same side.

**Appendicitis; Multiple Operations.**—Dr. CHARLES J. PROBEN presented a specimen of an appendix removed from one of his patients. The woman had come to him suffering from reflex gastro-intestinal derangements and symptoms due to proclivencia uteri. The uterus had been prolapsed in the second degree, for which he had performed colporrhaphy, perineorrhaphy, and celiotomy; after doing the former, he had opened the abdomen, having previously examined in order to determine the condition of the appendix, which he had distinctly palpated and found to be thickened and tender; in other words, a catarrhal appendicitis, with no symptoms but local tenderness. After doing double oophorectomy, he had sought the appendix, and found it to be exactly where he had located it by palpation—with thickened walls, and firm and rigid, of the diameter of an ordinary lead pencil. As it had been impossible to invert it, the omentum had been ligated, the peritoneal surfaces dissected off, the appendix cut off and ligated, and the peritoneal surfaces coaptated by catgut sutures. Hysterorrhaphy had been performed in order to anchor the uterus with closure of the abdominal walls. All these operations had been performed at one sitting; the patient had made an uneventful recovery, leaving the hospital at the end of the fourth week.

Dr. RUPP asked why the appendix had been removed.

Dr. PROBEN stated that the appendix had been removed not for symptoms, but because it had been diseased, and might in future give trouble. It could not be inverted, because there had been a stricture about the middle which had prevented it; consequently, excision had seemed preferable. He would not recommend laparotomy for catarrhal appendicitis, but, if performing it, he would search for the appendix, and if it was diseased remove or invert it, as the condition permitted.

(To be concluded.)

### Miscellany.

#### Borax for Preventing Rust on Surgical Instruments.

—In the *Presse médicale* for June 6th M. Marechal says that borax solution will prevent the accumulation of rust on surgical instruments, such as bistouries, scissors, needles, and forceps. They may be allowed, he says, to remain in a two-per-cent. solution of sodium borate for a year or two, and when they are withdrawn they will be found to be perfectly intact.

**The American Pædiatric Society's Collective Investigation into the Use of Antitoxine in the Treatment of Diphtheria in Private Practice.**—The following report was presented at the eighth annual meeting, in Montreal, Canada, on May 26, 1896:

This subject was chosen by the officers of the society for its eighth annual meeting, with the belief that a large amount of valuable experience not otherwise available might in this way be reached and collated. It was also believed that a more trustworthy estimate of the value of the serum treatment of diphtheria might thus be obtained than by statistics taken from hospital practice. There are very few hospitals in America that receive diphtheria patients, and the conditions under which patients are admitted to hospitals and their surroundings while there are so different from those of private practice that the measure of success in hospital cases can not be taken as an index of the results which have been obtained upon this side of the Atlantic with the new treatment.

In order, therefore, to obtain an expression of opinion from American physicians as to the serum treatment, after what had been, with most of them, their first year's experience, a circular letter was prepared and issued by the committee early in April. This was distributed through the members of the society as widely as could be done during the time allowed. An attempt was made to reach as many physicians as possible who had had experience with the remedy.

The first surprise of the committee was in learning how very widely the serum treatment had been employed, especially in the Eastern and mid-Western States. With more time, the number of cases collected might easily have been doubled and perhaps trebled; but enough reports have come in to enable one to see what opinion was held on the 1st of May, 1896, by American physicians who had used this remedy.

The circular letter asked for information upon the following points: Age; previous condition; duration of disease when the first injection was made; the number of injections; the extent of the membrane—tonsils, nose, pharynx, and larynx; whether or not the diagnosis was confirmed by culture; complications or sequelæ, viz., pneumonia, nephritis, sepsis, paralysis; the result; and remarks, including other treatment employed, the preparation of antitoxine used, and general impression drawn from the cases.

Reports were returned from 615 different physicians, with 3,628 cases. Of these, 244 cases have been excluded from our statistical tables. These were cases in which the disease was said to have been confined to the tonsils and the diagnosis not confirmed by culture, and therefore open to question. A few cases were reported in such doubtful terms as to leave the diagnosis uncertain. The figures herewith given are therefore made up from cases in which the diagnosis was confirmed by culture (embracing about two thirds of the whole number) and others giving pretty clear evidence of diphtheria, either in the fact that they had been contracted from other undoubted cases, or where the membrane had invaded other parts besides the tonsils, such as the palate, pharynx, nose, or larynx. It is possible that among the latter we have admitted some streptococcus cases, but the number of such is certainly very small. There are left, then, of these cases, 3,384 for analysis. These have been observed in the practice of 613 physicians from 114 cities and towns, in fifteen different States, the District of Columbia, and the Dominion of Canada.

In the general opinion of the reporters the type of diphtheria during the past year has not differed materially from that seen in previous years, so that it has been average diphtheria which has been treated. If there is any difference in the severity of the cases included in these reports from those of average diphtheria, it is that they embrace a rather larger proportion of very bad cases than are usually brought together in statistics. The cases, according to the extent of the membrane, are grouped as follows: In 593 the tonsils alone were involved. In 1,397 the tonsils and pharynx, the tonsils and nose, the pharynx and nose, or all three were affected. In 1,256 cases the larynx was affected either alone or with the tonsils, pharynx, and nose, one or all. In many instances the statement is made by the reporters that the serum was resorted to only when the condition of the patient had become alarmingly worse under ordinary methods of treatment. This is shown by the unusually large number of cases in which injections were made late in the disease. Again, many physicians being as yet in some dread of the unfavorable effects of the serum have hesitated to use it in mild cases and have given it only in those which from the onset gave evidence of being of a severe type. The expense of the serum has unquestionably deterred many from employing it in mild cases. These facts, it is believed, will more than outweigh the bias of any antitoxine enthusiasts by including many mild cases which would have recovered under any treatment. It will, however, be remembered that tonsillar cases not confirmed by culture have not been included.

Only two reports embracing a series of over 100 cases have been received, most of the observers having sent in from five to twenty cases, although there are many reports of single cases, particularly of single fatal ones.

In addition to this material which has come in response to the circular, there have been placed at the disposal of the committee by the courtesy of Dr. H. M. Biggs, 942 cases treated in the patients' homes in the tenements of New York. Of these, 856 were injected by the corps of inspectors of the New York health board, upon the request of the attending physician, and eighty-six others were treated by physicians receiving free antitoxine from the health board. In the first group the diagnosis of diphtheria was confirmed by culture in every case, and in all of the latter except twenty-six; in these the diagnosis rested upon extensive membranous deposits or laryngeal invasion. The cases of the New York health board were of a more than ordinarily severe type, 485, or more than fifty per cent. of the patients, being reported as being in bad condition at the time of injection; to mild cases the inspectors were not often called. Further, an unusually large number of them (thirty-eight per cent.) were injected on or after the fourth day of the disease. In 182 of these cases only the tonsils were affected; in 466 the tonsils with the pharynx or nose, the pharynx and nose, or all three; in 294 the larynx was invaded either with or without disease of the tonsils, nose or pharynx.

Through the courtesy of Dr. Biggs the committee is able to include also a partial report upon 1,468 cases from Chicago, treated in the patients' homes in that city by a corps of inspectors of the health department. It was the custom in Chicago to send an inspector to every tenement house case reported, and to administer the serum unless it was refused by the parents. These cases were therefore treated much earlier and the re-

sults were correspondingly better than were obtained in New York, although the serum used was the same in both cities, viz., that of the New York health board.

THE RESULT AS INFLUENCED BY THE TIME OF IN-

JECTION.—In Table I are given the results obtained in these three different groups of cases, classified according to the day on which they received the first injection of serum antitoxine.

TABLE I.—*Day of Injection and Result.*

	INJECTED ON 1ST DAY.			INJECTED ON 2D DAY.			INJECTED ON 3D DAY.			INJECTED ON 4TH DAY.			INJECTED ON OR AFTER 5TH DAY.			DAY OF INJECTION UNKNOWN.			TOTALS.		
	Cases.	Deaths.	Mortality per cent.	Cases.	Deaths.	Mortality per cent.	Cases.	Deaths.	Mortality per cent.	Cases.	Deaths.	Mortality per cent.	Cases.	Deaths.	Mortality per cent.	Cases.	Deaths.	Mortality per cent.	Cases.	Deaths.	Mortality per cent.
The committee's report..	764	38	4.9	1,055	89	8.3	620	79	12.7	336	77	22.9	390	152	38.9	215	15	7.0	3,384	450	13.0
New York Health Board..	126	11	8.7	215	26	12.0	228	37	16.6	153	32	20.9	203	59	29.0	17	4	23.7	912	169	17.8
Chicago Health Board...	106	0	0.0	336	5	1.5	660	18	2.7	269	38	14.1	97	33	34.0	0	0	0.0	1,468	94	6.4
Totals .....	996	49	4.9	1,616	120	7.4	1,058	134	8.8	758	147	20.7	690	244	35.3	232	19	8.2	5,794	713	12.3

The grand total gives 5,794 cases with 713 deaths, or a mortality of 12.3 per cent., including every case returned; but the reports show that 218 cases were moribund at the time of injection or died within twenty-four hours of the first injection. Should these be excluded there would remain 5,576 cases (in which the serum may be said to have had a chance) with a mortality of 8.8 per cent.

Of the 4,120 cases of injection during the first three days there were 303 deaths—a mortality of 7.3 per cent., including every case returned. If from these we deduct the cases in which the patients were moribund at the time of injection, or died within twenty-four hours, we have 4,013 cases, with a mortality of 4.8 per cent. Behring's original contention, that if patients were injected on the first or second day the mortality would not be five per cent., is more than substantiated by these figures. The good results obtained in third-day injections were a great surprise to your committee. But after three days have passed the mortality rises rapidly, and does not differ materially from that of ordinary diphtheria statistics. Our figures emphasize the statement, so often made, that relatively little benefit is seen from antitoxine after three days; however, it must be said that striking improvement has in some cases been seen even when the serum has been injected as late as the fifth or sixth day. The duration of the disease, therefore, is no contraindication to its use.

THE INFLUENCE OF BACTERIOLOGICAL DIAGNOSIS UPON THE STATISTICS.—This is shown in Table II.

In the cases in which the diagnosis was not confirmed by a bacteriological examination the mortality is thus five per cent. higher than in the bacteriological cases. This difference is to be explained by two facts: first, as already stated, that we have excluded from our

reports all tonsillar cases (and hence most of the very mild ones) not confirmed by bacteriological examinations; and secondly, by the fact that this group of cases comprises those treated in the country where physicians have hesitated to use antitoxine unless the type of the disease was a grave one, and where also a large proportion of the injections were made later than in the cities. However, should we leave out the moribund cases, the mortality is but 9.6 per cent., which differs but slightly from that of the cases confirmed by bacteriological diagnosis.

TABLE II.—*Diagnosis Confirmed by Bacteriological Examination.*

	Cases.	Deaths.	Mortality per cent.
Committee's reports .....	2,453	302	12.3
New York Board of Health .....	916	160	16.9
Chicago Board of Health .....	1,468	94	6.4
Totals .....	4,837	556	11.4
(Excluding 145 cases which were moribund or which died in 24 hours) .....			8.7

*Diagnosis from Clinical Evidence Only.*

	Cases.	Deaths.	Mortality per cent.
Committee's reports .....	931	148	15.7
New York Board of Health .....	26	9	34.6
Totals .....	957	157	16.3
(Excluding 72 cases of patients either moribund or dying in twenty-four hours) .....			9.6

In our subsequent statistics we shall consider together all the cases bacteriologically confirmed and otherwise, as the statistics are not materially altered by this grouping.

THE RESULTS AS MODIFIED BY THE AGE OF THE PATIENTS.—Unfortunately the ages have not been fur-

TABLE III.—*Age and Result of Treatment.*

Mortality, excluding moribund cases .....			19.2			13.3			8.7			3.3			3.2			2.1

nished in the report of the Chicago cases, and we have therefore only the cases reported to the committee and those from the New York board of health for analysis. In Table III are shown the mortality of the different ages grouped separately.

The highest mortality is seen as in all reports to be in the cases of children under two years, but including all those returned, even those that were moribund when injected, the death-rate was but 23.3 per cent. (21.7 per cent. of the committee's cases), while if we exclude cases of patients moribund when injected or dying within the first twenty-four hours, it falls to 19.2 per cent.

After the second year there is noticed a steady decline in mortality up to adult life. In many of the reports previously published the statement has been made that no striking improvement in results was observed in cases of adults treated by the serum. Our figures strongly contradict this opinion. In 359 cases of persons over fifteen years old, which were returned, there were but thirteen deaths. That the reader may judge for himself how far antitoxine is to be held responsible for the result, a brief summary of these thirteen cases is appended.

Case I.—Fifteen years old; injected on the fourth day; membrane covering tonsils and pharynx; profoundly septic, sinking rapidly when injected; died in two hours. "My only death in seventeen cases" (Jones, Gloucester, Mass.).

Case II.—Forty-four years old; injected on the fourth day; membrane on the tonsils and pharynx; in bad condition; died three hours after injection. The tonsils had been previously incised, the early diagnosis having been quinsy.

Case III.—Thirty-one years old; injected on the sixth day; membrane on the tonsils, nose, pharynx, and larynx; intubation; sepsis; in bad condition; lived eight hours after injection.

Case IV.—Thirty-five years old; injected on the fifth day; membrane on the pharynx and nose (?); in bad condition; septic; died in twelve hours.

Case V.—Sixty years old; in bad condition; had serious mitral regurgitation; injected on the fourth day; membrane covering tonsils, pharynx, and larynx; died from heart failure on following day.

Case VI.—Sixty years old; "kidney trouble for years;" injected on the third day; very extensive membrane, covering tonsils, pharynx and nose; profound sepsis; in bad condition; died suddenly on the day after injection.

Case VII.—Seventeen years old; in bad condition; convalescing from measles; enormous adenopathy; profound sepsis; exceedingly high temperature; membrane covering tonsils and nose; injected at the end of forty-eight hours; three injections, temporary improvement after each one; duration of life not given.

Case VIII.—Fifteen years old; in bad condition; injected on the ninth day; membrane covering tonsils, nose, pharynx, and larynx; no operation; enormous infiltration of the tissues of the neck; nephritis; sepsis; lived four days and died of sepsis.

Case IX.—Twenty years old; injected on the third day; membrane upon the tonsils, nose, pharynx, and larynx; "a stubborn patient who got up before he was allowed, and died suddenly after it."

Case X.—Twenty-five years old; injected on the fifth day; membrane covering both tonsils, entire pharynx, and completely occluding nose; nephritis and sepsis;

throat cleared off entirely; died suddenly on the fourteenth day from cardiac paralysis.

Case XI.—Nineteen years old; injected on the fifth day; membrane upon the tonsils and pharynx; profound sepsis; duration of life unknown.

Case XII.—Twenty-two years old; injected on the fourth day; membrane on the tonsils and gums; sepsis; died on the sixth day.

Case XIII.—The well-known Brooklyn case, reported in 1895. Girl, sixteen years old, who died suddenly ten minutes after injection.

Such are the cases of adults whom antitoxine failed to cure. Four of them were moribund at the time of injection, no one of them living over twelve hours. Two, both sixty years old, were already crippled by previous organic disease, one of the heart, and the other of the kidneys. In the measles case there was undoubted evidence of streptococcus septicæmia. Only two of them were injected as early as the third day; three of them on the fifth day; and one on the ninth day. Omitting the four moribund cases, the mortality of 355 cases of adults treated with the serum is 2.5 per cent.

PARALYSIS.—Reliable data upon this point and those hereafter to be mentioned are to be had only from the 3,384 reports returned to the committee. Of these, paralytic sequelæ appeared in 328 cases, 9.7 per cent. Of the 2,934 cases of recovery, paralysis was present in 276, or 9.4 per cent. Of the 450 cases in which the patients died, paralysis was noted in fifty-two, or 11.4 per cent.

The variety of the paralysis and the date of injection are shown in the following table:

TABLE IV.—Variety of Paralysis and the Day of Injection.

	Cases.	DAY OF INJECTION.					Unknown.
		1st day.	2d day.	3d day.	4th day.	5th day.	
<i>Recovery Cases</i>

\* Cases of heart failure occurring at the height of the disease have not been included here, although they are mentioned among the cases of cardiac paralysis in the table of fatal cases.

Observations of some of the individual cases are interesting, particularly those of cardiac paralysis. It is twice stated that the child had gotten up and walked out of the house, where it was found dead. Twice death occurred after sitting up suddenly; once, on jumping from one bed into another. One patient of twenty years got up contrary to orders and died soon afterward. Another patient was apparently well until he indulged in

a large quantity of cake and candy, soon after which cardiac symptoms developed, and he died shortly. One case was that of a woman sixty years old, who had serious organic cardiac disease.

It is difficult from these statistics to state what protective power the serum may have over the nerve cells and fibres. Apparently this is not great unless the injections are made early in the disease, and even then in severe cases the amount of damage done to these tissues in twenty-four hours may be very great, even irreparable. Time is not the only element in estimating the effect of the diphtheria toxins.

Great discrepancy exists in the statements made regarding the frequency of paralytic sequelæ after diphtheria. In a series of 1,000 cases reported by Lennox Browne, paralytic sequelæ were present in fourteen per cent. In 2,448 cases by Sanné, paralysis was noted in eleven per cent. In the series of cases here reported, the difference is slightly in favor of the antitoxine treatment, but paralysis is certainly frequent enough to show how extremely susceptible the nervous elements are to the diphtheria toxins. One thing is quite striking from a study of these cases, and that is the proportion of patients that have died from late cardiac paralysis. That very many of them would undoubtedly have succumbed earlier in the disease from suffocation (laryngeal cases) or diphtheritic toxæmia, had the serum not been employed, is beyond question. Although the serum is able to rescue the patients in even many such desperate cases, it can not overcome the effects of the toxins upon the cells which have occurred before it was injected.

**SEPSIS.**—Sepsis is stated to have been present in 362 of the 3,384 cases, or 10.7 per cent. It was present in 145, or thirty-three per cent., of the fatal cases. Some explanation is necessary for a correct appreciation of these figures. The majority of the reporters, it is plain from their remarks, have not distinguished between diphtheritic toxæmia and streptococcus sepsis. The former is certainly meant in the great majority of the cases. There is a very small proportion in which there is evidence of streptococcus sepsis. The six cases complicating measles and the five complicating scarlet fever, however, should possibly be included in this list.

**NEPHRITIS.**—The statements on this point are quite unsatisfactory. The reports state that nephritis was present 350 times, or in ten per cent. of the cases. On the one hand it must be stated that the diagnosis of nephritis rests in many cases simply upon the presence of albumin in the urine; but, on the other hand, it is true that in a large number of the cases, more than half, no examination of the urine is recorded as having been made, so that it is impossible to state with anything like approximate accuracy the frequency of nephritis in these cases. Of the 450 fatal cases, the presence of nephritis is mentioned without qualification or explanation in thirty-nine cases; these being usually put down also as septic, dying in the acute stage of the disease. There are fifteen fatal cases, however, in which the renal disease was stated as the cause of death. In no less than nine the nephritis occurred late in the disease, usually during the second or third week. In these fifteen cases the evidence of severe nephritis was conclusive, such symptoms being present as dropsy, suppression of urine, with coma or convulsions.

**BRONCHO-PNEUMONIA.**—Broncho-pneumonia is stated to have been present in 193 of the 3,384 cases, or 5.9 per cent., a remarkably small proportion when compared with hospital statistics. Among the patients that

recovered, broncho-pneumonia was noted 114 times, or in 3.8 per cent.; among the fatal cases, seventy-nine times, or in 17.5 per cent., but in only about one half of these was the pneumonia the cause of death. Of these, (thirty-seven were laryngeal cases operated upon late, ten were septic cases, and the pulmonary disease was coincident with the height of the diphtheritic process. In seven pneumonia was independent of both the above-mentioned conditions, occurring late in the disease in all but two.

**LARYNGEAL CASES.**—Of the 3,384 cases reported to the committee, the larynx is stated to have been involved in 1,256 cases, or 37.5 per cent. This proportion is somewhat higher than is usual, and is partly explained by the fact that several physicians have sent in the reports only of their laryngeal cases. These laryngeal cases occurred in the practice of 379 physicians.

In 691, or a little more than one half the number, no operation was done, and in this group there were 128 deaths. In forty-eight of them laryngeal obstruction was responsible for the fatal issue, operation being refused by the parents, or no reason for its being neglected having been given. In the eighty remaining fatal cases the patients died of other complications, and not from the laryngeal disease.

In the 563 cases, therefore, or 16.9 per cent. of the whole number, there was clinical evidence that the larynx was involved, and yet recovery took place without operation. In many of these cases the symptoms of stenosis were severe, and yet disappeared after injection without intubation. No one feature of the cases of diphtheria treated by antitoxine has excited more surprise among the physicians who have reported them than the prompt arrest, by the timely administration of the serum, of membrane which was rapidly spreading downward below the larynx. Such expressions abound in the reports as "wonderful," "marvelous," "prepared to do intubation, but at my next visit the patient was so much better it was unnecessary," "in all my experience with diphtheria have never seen anything like it before," "no unprejudiced mind could see such effects and not be convinced of the value of the serum," etc.

In establishing the value of the serum, nothing has been so convincing as the ability of antitoxine, properly administered, to check the rapid spreading of membrane downward in the respiratory tract, as is attested by the observations of more than 350 physicians who have sent in reports.

Turning now to the operative cases, we find the same remarkable effects of the antitoxine noticeable. Operations were done in 565 cases, or in 16.7 per cent. of the entire number reported. Intubation was performed 533 times with 138 deaths, or a mortality of 25.9 per cent. In the foregoing are included nine cases in which a secondary tracheotomy was done, with seven deaths. In thirty-two tracheotomy only was done, with twelve deaths, a mortality of 37.4 per cent. In the 565 operative cases, sixty-six patients were either moribund at the time of operation, or died within twenty-four hours after injection. Should these be deducted, there remain 499 operated upon by intubation or tracheotomy, with 84 deaths, a mortality of 16.9 per cent.

In the 2,819 not operated upon, there were 312 deaths, a mortality of 11.3 per cent. Deducting the moribund, or those dying within twenty-four hours after injection, the total mortality of all non-operative cases was 9.12 per cent.

Let us compare the results of intubation in cases

in which the serum was used with those obtained with this operation before the serum was introduced. Of 5,546 intubation cases in the practice of 212 physicians, collected by McNaughton and Madden (1892), the mortality was 69.5 per cent. Since that time statistics have improved materially by the general use (in and about New York, at least) of calomel fumigations. With this addition, the best results published (those of Brown) showed in 279 cases a mortality of 51.6 per cent.

Let us put beside the cases of McNaughton and Madden the 533 intubations with antitoxine, with 25.9 per cent. mortality. With Brown's personal cases let us compare those of the fourteen observers who have reported to the committee ten or more intubation operations in cases of patients injected with serum. These comprise 280 cases with sixty-five deaths, a mortality of 23.2 per cent. In both comparisons the mortality without the serum is more than twice as great as in the cases in which serum was used.

The reports of some individual observers concerning intubation with the serum are interesting:

Nell, New York: twenty-seven operations, with twenty-seven recoveries.

Rosenthal, Philadelphia: eighteen operations, with sixteen recoveries.

Booker, Baltimore: seventeen operations, with seventeen recoveries, including one aged ten months, and one seven and a half months.

Seward, New York: eight operations, with eight recoveries.

McNaughton, Brooklyn: "In my last seventy-two operations without serum, mortality 66.6 per cent.; in my first seventy-two operations with serum, mortality 33.3 per cent."

O'Dwyer, New York: "In my last 100 intubations, first seventy, without serum, mortality seventy-three per cent.; last thirty, with serum, mortality 33.3 per cent."

But even these figures do not adequately express the benefit of antitoxine in laryngeal cases. Witness the fact that over one half the laryngeal cases did not require operation at all. Formerly ten per cent. of recoveries was the record for laryngeal cases not operated upon. Surely, if it does nothing else, the serum saves at least double the number of patients with laryngeal diphtheria that have been saved by any other method of treatment.

The great preponderance of intubation over tracheotomy operations shows how much more highly the profession in this country esteems the former operation.

**A STUDY OF THE FATAL CASES.**—Of the 450 fatal cases in the committee's report, 229 of the patients, or one half, received their first injection of the serum on or after the fourth day of the disease, and 152, or over one third of these, on or after the fifth day.

There were fifty-eight cases in which it was stated that the child was moribund at the time of injection, the serum being administered without the slightest expectation of benefit, but at the earnest solicitation of the parents.

There remain 350 cases in which the cause of death could be pretty accurately determined by the reports. In these the patients died from the following causes, the most important cause being placed first:

Sepsis (including diphtheritic toxæmia) was the cause of death in 105 cases, in which sixteen patients had nephritis, four were intubated or tracheotomized, two, in laryngeal cases, were not operated upon, four had paralysis, one had pneumonia, and in one the fatal sepsis was attributed to a traumatic condition of the left knee.

Cardiac paralysis was the cause of death in fifty-three cases. Under this head are included cases of sudden heart failure occurring at the height of the disease (twenty-one in number) as well as those more commonly designated as heart paralysis, where death occurred suddenly after the throat cleared off. Of the latter there were thirty-two examples; four of these patients had throat paralysis, nineteen cases were septic, eight patients had nephritis, five were intubated, and one was tracheotomized.

Broncho-pneumonia was put down as the cause of death in fifty-four cases. In thirty-seven of these it followed laryngeal diphtheria; of these patients, twenty-two were intubated and four tracheotomized; two had nephritis; nine cases were septic. Broncho-pneumonia and sepsis were the causes of death in ten cases, in which three patients had nephritis and one general paralysis. Broncho-pneumonia caused death in seven cases, apart from sepsis or laryngeal diphtheria; in these, only one patient had nephritis; one died from heart failure; and in five pneumonia came on late in the disease.

Laryngeal diphtheria without operation caused death in forty-eight cases. In some of these the operation was refused by the parents, in others it was neglected by the physician, the patients dying of asphyxia; three of these patients had nephritis, four cases were septic, two patients had pneumonia, and one had sepsis and nephritis.

Diphtheritic tracheitis or bronchitis caused death in eleven cases; all of these patients were intubated, and in two there was evidence of the existence of membrane in the bronchi before operation. There were thirty-three other cases in which death followed laryngeal diphtheria without the supervention of pneumonia. It is highly probable that in some of these death was due to membranous tracheitis or bronchitis. All of the patients were operated upon; ten were septic, two had paralysis, and one had nephritis.

Sudden obstruction of the intubation tube was the cause of death in three other laryngeal cases.

The tube was coughed up in three cases, fatal asphyxia occurring before the physician could be summoned.

Died on the table during tracheotomy, one patient.

Nephritis was the cause of death in fifteen cases; seven of these were septic, and three patients had been intubated.

General paralysis was the cause of death in five cases; in all probably the pneumogastric was involved.

Paralysis of the respiratory muscles produced death in one case, one of laryngeal diphtheria, in which intubation was performed, which was complicated by broncho-pneumonia.

Measles associated with diphtheria produced death in six cases; five of these were laryngeal and the patients were intubated; in two there was pneumonia, and in two sepsis. Diphtheria developed during the height of the measles or immediately followed it.

Scarlet fever with diphtheria was the cause of death in six cases; in three of these there were broncho-pneumonia, nephritis, and sepsis; in two scarlet fever preceded diphtheria, and in one of these there was sepsis with gangrene of the tonsils. In the sixth case the patient died of scarlet fever, which developed during convalescence from the diphtheria.

Gangrene of the cervical glands or cellular tissue of the neck was the cause of death in two cases associated with profound general sepsis.

Endocarditis caused death in one case, nineteen days after the diphtheria.

Diphtheritic inflammation of the tracheal wound with sepsis caused death in one case.

*General tuberculosis*, five weeks after diphtheria, was assigned as the cause of death in one case.

*Exhaustion* was the cause of death in three cases, one a protracted case, another complicated by pneumonia and sepsis, one by nephritis.

*Convulsions* were the cause of death in three cases apart from disease of the kidneys. In one, the well-known Brooklyn case, the girl died in ten minutes after the injection; in another, twenty-four hours after injection; in the third the particulars were not given.

*Meningitis* was assigned as the cause of death in one case.

**THE KIND OF ANTITOXINE USED.**—They are given in the order of frequency with which they have been used. First, the serum prepared by the New York board of health; second, Behring's; third, Gibier's; \* fourth, Mulford's; fifth, Aronson's; sixth, Roux's. In addition a large number of cases are reported as having been treated by the serum prepared by the health boards of different cities—Brooklyn, Newark, Rochester, Pittsburgh, etc. The largest number of cases have been treated by the serum prepared by the New York health board, a very large number by Behring's serum, all others being relatively in small numbers.

**DOSE AND NUMBER OF INJECTIONS.**—In the great majority of cases but one injection is reported. In very severe ones two and three have been given. The largest amount is in a case by Weimer (Chicago), who gave eighteen injections of Behring's serum in a laryngeal case in a child thirteen years old. Another instance of ten injections is reported with no unfavorable symptoms.

As a rule the dose has been smaller in antitoxine units than is now considered advisable, particularly in many of the laryngeal cases and others of injection later than the second day.

**CASES OF INJECTION REASONABLY EARLY (DURING THE FIRST THREE DAYS) IN WHICH ANTITOXINE IS SAID TO HAVE PRODUCED NO EFFECT, THE DISEASE ENDING FATAU.**—These cases are nineteen in number. Brief reports are introduced that the reader may judge to what degree they may be regarded as a test of the serum treatment. In our statistical tables all of them have been included among the fatal cases.

In Cases I and II the cultures were reported negative. Case I, by Gallagher, New York: Child, eighteen months old; septic; although no eruption was present, the reporter was "inclined on reflection to regard this case as one of scarlatinal sore throat."

Case II, by Potter, Buffalo: Male, fourteen months old; two cultures made, but no Loeffler bacilli found; membrane in the nose and pharynx. Injected on the third day one dose of Behring's serum No. 1. No improvement; death from sepsis. "Probably pseudo-diphtheria" (I. H. P.).

In Cases III to IX no cultures were made.

Case III, by Tefft, New Rochelle: Seven years old; injected after eighteen hours' illness two injections of Behring's No. 2 serum; membrane on the tonsils, pharynx, and nose; no effect observed from injections, patient dying on the third day.

Case IV, by Tefft: Male, four years old; membrane

on the tonsils and pharynx; injected after thirty-six hours' illness with Behring's No. 2; died on the third day; no noticeable effect from the injection.

Case V, by Tefft: Six years old; membrane on the tonsils, nose, and pharynx; septic; injected after thirty-six hours' illness three injections of Behring's No. 2. "Saw no effect from the injections, the disease going steadily on to a fatal termination."

Case VI, by Cameron, Montreal: Two years and a half old; fifty hours ill; membrane on the tonsils, nose, and pharynx; septic; no improvement noticed, and child died twenty hours after injection.

Case VII, by Baker, Newtonville, Mass.: Three years old; laryngeal diphtheria; injected on the third day 10 c. c. Roux's serum; cyanosis; intubation; temperature 103° F., and continued high until death in eighteen hours after operation; injections had no effect.

Case VIII, by Anderson, New York: Three years old; injected after three hours' illness; membrane on the tonsils, nose, and pharynx; one injection, New York health board antitoxine. "A case of malignant diphtheria, full duration twenty-four hours."

Case IX, by McLain, Washington: Four years old; twelve hours sick; membrane on the pharynx and larynx; two injections; no operation; first injection early in the morning, the other early in the afternoon; died the same day; no change in the condition; antitoxine had no apparent effect.

In Cases X to XIII diphtheria complicated measles, all reported by W. T. Alexander, New York. Disease confined to the larynx in all; in three the stenosis developed during measles, and in one while the patient was convalescing from measles; diagnosis confirmed by culture in every case, and in all intubation performed. Antitoxine seemed to have no effect, the cases going on to a fatal termination; all received their injections within twenty-four hours after the laryngeal symptoms appeared.

In three cases—XIV to XVI—the type of the disease was malignant from the outset.

Case XIV, by Lloyd, Philadelphia: Fifteen months old; injected after thirty-six hours' illness; diagnosis confirmed by culture; membrane covered the tonsils, pharynx, nose, and larynx; intubation; sepsis; death on the fifth day. Although antitoxine was used as promptly as possible no perceptible effect noticed. One injection, Behring's No. 3, was given.

Case XV, by Wert, Mount Vernon, N. Y.: Eighteen months old; injected on the third day; diagnosis confirmed by culture; membrane on the tonsils and pharynx. "Very intense type of the disease." Antitoxine could not be procured before the third day; Gibier's serum used. "Died suddenly in apparent convulsions about ten hours after injection; urine not examined; very little passed."

Case XVI, by Ingraham: Six years old; membrane covered the tonsils, pharynx, and larynx; diagnosis confirmed by culture; pneumonia present; condition very bad; injected after two and a half days' illness; three injections of Behring's serum; no benefit noticed.

Case XVII, by Johnson, Buffalo: Three years old; twelve hours ill; case septic from the start; membrane on the tonsils, pharynx, and larynx; diagnosis confirmed by culture. "Antitoxine apparently had very little effect."

Case XVIII, by Baker, Newtonville, Mass.: Two years and a half old; twenty hours ill; disease confined to larynx; diagnosis confirmed by culture; one injection

\* It is worthy of note that in the tests made by the State Board of Health of Massachusetts, published under date of April 6, 1896, this serum was found far below the standard as labeled upon the bottle; thus, a package marked to contain 2,500 units, by test was found to contain fewer than 700. All the other varieties of serum tested were found essentially up to the standard.

of Gibier's serum; intubation. "Was doing well a few minutes before death, when child got up in its crib, changed color, and died almost immediately." Death attributed to "sudden heart failure; found no obstruction of the tube."

CASE XIX, by Story, Washington: Five years old; in fair condition; thirty-six hours ill; diagnosis confirmed by culture; membrane on the tonsils, pharynx, and larynx; one injection of United States Marine-Hospital antitoxine; injection produced no effect.

CASES IN WHICH UNFAVORABLE SYMPTOMS WERE, MIGHT HAVE BEEN, OR WERE BELIEVED TO HAVE BEEN, DUE TO ANTITOXINE INJECTIONS.—Only three cases reported to the committee could by any possibility be placed in this category. All of the details furnished by the reporters are reproduced:

CASE I, by Kortright, Brooklyn: Sudden death in convulsions ten minutes after injection. This case is the already well-known Valentine case, occurring in Brooklyn in the spring of 1895. The principal points were as follows: A girl, sixteen years old; in good condition; tonsillar diphtheria; diagnosis confirmed by culture; injected on the first day with 10 c. c. Behring's serum; died in convulsions ten minutes later.

CASE II, by Kerley, New York: Fairly healthy boy, two years and a half old; membrane on tonsils, pharynx, and in nose. Diagnosis confirmed by culture; injected on the morning of the fourth day with 10 c. c. (1,000 units) New York health board serum; temperature at time of injection 100.1° F.; no sepsis, and child apparently not very sick; urine free from albumin. Distinctly worse after injection; in ten hours temperature rose to 103° F.; urine albuminous; throat cleared off rapidly, but marked prostration and great anæmia, with irregular fluctuating temperature, continued, and death from exhaustion with heart failure four days after the use of the serum.

CASE III, by Eynon, New York: Male, three years and a half old; diagnosis confirmed by culture; two days ill; membrane on tonsils and in nose; two injections New York health board serum. "A rapid nephritis developed after the second injection, causing coma, convulsions, and death twenty hours after the second injection." In response to an inquiry for further particulars the following was received: "The case seemed a mild one, but the injection was given one afternoon and repeated the following afternoon, about fifteen hundred units in all. The urine up to that time had not been examined. About fourteen or sixteen hours after the second injection unfavorable symptoms began to develop pointing to infection of the kidneys. The urine was found to be loaded with albumin. My impression at the time was that the antitoxine either produced, hastened, or intensified nephritis, thereby causing the fatal termination."

In regard to the three fatal cases just cited, Case I is wholly unexplained. In Case II the query arises, Did this sudden change hinge upon the injection of the serum, or was it one of those unexplained abrupt changes for the worse in a case apparently progressing favorably so often observed in diphtheria? As regards Case III, it will be seen from the letter that the evidence is not at all conclusive. All details available are given, and the reader may draw his own conclusions.

CLINICAL COMMENTS.—The following are selected from hundreds which have been received, and may be taken fairly to represent the sentiments of the physicians who have sent in reports:

Dr. Douglas H. Stewart, New York, sends reports of four cases, all desperate ones, and all "presumably fatal under any other form of treatment." Very extensive membrane in all; larynx involved in three; in one neglected case in a child three years old, injected upon the fifth day; the membrane covered the tonsils, nose, pharynx, and larynx. Broncho-pneumonia, nephritis, and sepsis all present. Temperature 107° F. at the time of the first injection. Prostration so great that he dared not attempt intubation. Believes that this case would certainly have been fatal in a few hours without antitoxine. Perfect recovery.

In another case, of a child, three years old, membrane first discovered in the left ear, next morning seen upon the tonsils, and spread in a few hours over the pharynx into the larynx and trachea. Intubation necessary in a few hours; had never seen membrane spread so rapidly as in this child. Urine albuminous; membrane subsequently expelled from larynx and trachea in large casts, with profuse bloody expectoration. Complete recovery on the ninth day. The physician describes this as "the very worst case of diphtheria that has ever come under my notice." Five thousand four hundred antitoxine units were given in four injections. He remarks: "My experiences in the past have been so very unfortunate that the advocates of antiseptics or therapeutics were a constant surprise to me. It has been my fate to have the most desperate cases unloaded upon my shoulders. I had been forced into the belief that the profession was absolutely powerless in the presence of true diphtheria; have lost case after case with tube in the larynx and calomel fumigations at work. Previous to antitoxine my only hope had become centred in Nature and stimulants. In two years have not lost a single case, and surely I may be pardoned if I suffer from diphtheriophobia in a subacute form, and use antitoxine sometimes unnecessarily."

Dr. L. L. Danforth, New York, states that during his twenty-two years of practice in New York he has seen many fatal cases of diphtheria, had used all kinds of remedies, mainly those of the homœopathic school, and while he had as much confidence in the latter as in anything else, he had seen so many deaths during the year past that he "hailed with delight the advent of antitoxine, and determined to use it." Reports five cases, all of a severe type. "The result in every case had been marvelous. I would not dare to treat a case now without antitoxine."

Dr. H. W. Berg, New York, reporting fourteen cases, says: "I have not yet ceased to be surprised at the recovery of some of these cases, which, in the light of my former experience with diphtheria treated without antitoxine, seemed to be irretrievably lost."

Dr. George McNaughton, Brooklyn, reports seventy-two laryngeal cases, with twenty-four deaths; sixty-seven of these were intubated, with twenty-one deaths. He states that he has kept no records of cases other than laryngeal ones, as these seemed the best test of the serum treatment. He believes that if the serum is used early, very many cases will not need operation for the relief of stenosis. "I would urge the use of antitoxine in all cases of croup in any patient who has an exudation upon the pharynx; would not wait for bacteriological confirmation of diagnosis, for in so doing valuable time is lost." Has noticed that the tube is coughed up more frequently in injected cases, and believed this due to the fact that the swelling of the tissues subsides at an earlier date.

Dr. D. C. Moriarta, Saratoga, reporting four cases, says that the first was a malignant one and "I only used the remedy because I am health officer and was urged to do so, as the type of the disease was that from which I have seen recovery but once in eleven years." Boy, five years old, four days ill when injected; great prostration, rapid breathing, and he was "practically gone." Nares filled and tonsils and pharynx covered; severe nasal hemorrhage; cervical glands greatly swollen; heart's action very frequent and feeble; child unable to lie down. Behring's serum twenty cubic centimetres injected; in six hours evidently more comfortable; in eighteen hours decidedly improved; in twenty-four hours sitting up and feeling much better; in forty-eight hours all urgent symptoms gone and membrane loosening. Subsequently had nephritis which lasted six weeks, and multiple neuritis which persisted for three months, but ultimately recovered perfectly. "I send this report because it converted me. No unbiased person familiar with diphtheria could see such results as this and not feel there must be good in it."

Dr. F. M. Crandall, New York, sends report of a child seven years old. Membrane on the tonsils and in larynx, with croup for forty hours when antitoxine was injected and intubation done. Progress of the disease had been rapid; semi-stupor and eyes half open; very feeble rapid pulse; intense toxæmia; general cyanosis. Both cyanosis and dyspnoea persisted after intubation, showing clearly the presence of membrane below the tube. Case regarded as "absolutely hopeless." The first change was seen in the disappearance of toxæmia, with improvement in the pulse, clearness of the mind, etc.; later a change in the local condition; large masses of membrane were expelled from the larynx and trachea, necessitating frequent removals of the tube. Tube finally removed in a week with complete recovery.

Dr. Reynolds, of Baltimore, mentions a case showing the danger of relying too implicitly upon the bacteriological diagnosis. Male, three years. Culture reported only staphylococcus and streptococcus, consequently injection delayed until the fifth day, when membrane covered tonsils, nose, and pharynx. Child died two days later. A sister subsequently contracted the disease, received antitoxine on the third day and recovered. The reporter would not wholly rely upon the culture test for diagnosis.

**SUMMARY.**—(1) The report includes returns from 615 physicians. Of this number more than 600 have pronounced themselves as strongly in favor of the serum treatment, the great majority being enthusiastic in its advocacy.

(2) The cases included have been drawn from localities widely separated from each other, so that any peculiarity of local conditions to which might be ascribed the favorable reports must be excluded.

(3) The report includes the record of every case returned except those in which the evidence of diphtheria was clearly questionable. It will be noted that doubtful cases which recovered have been excluded, while doubtful cases which were fatal have been included.

(4) No new cases of sudden death immediately after injection have been returned.

(5) The number of cases of injection reasonably early in which the serum appeared not to influence the progress of the disease was but nineteen, these being made up of nine cases of somewhat doubtful diagnosis; four cases of diphtheria complicating measles, and three malignant cases in which the progress was so rapid that the cases had passed beyond any reasonable prospect of re-

covery before the serum was used. In two of these the serum was of uncertain strength and of doubtful value.

(6) The number of cases in which the patients appeared to have been made worse by serum were three, and among these there is only one new case in which the result may fairly be attributed to the injection.

(7) The general mortality in the 5,794 cases reported was 12.3 per cent.; excluding the cases of patients moribund at the time of injection or dying within twenty-four hours, it was 8.8 per cent.

(8) The most striking improvement was seen in the cases of injection during the first three days. Of 4,120 such cases the mortality was 7.3 per cent.; excluding cases of persons moribund at the time of injection or dying within twenty-four hours, it was 4.8 per cent.

(9) The mortality of 1,448 cases of injection on or after the fourth day was twenty-seven per cent.

(10) The most convincing argument, and to the minds of the committee an absolutely unanswerable one, in favor of serum therapy is found in the results obtained in the 1,256 laryngeal cases (membranous croup). In one half of these recovery took place without operation, in a large proportion of which the symptoms of stenosis were severe. Of the 533 cases in which intubation was performed the mortality was 25.9 per cent., or less than half as great as has ever been reported by any other method of treatment.

(11) The proportion of cases of broncho-pneumonia—5.9 per cent.—is very small and in striking contrast to results published from hospital sources.

(12) As against the two or three instances in which the serum is believed to have acted unfavorably upon the heart might be cited a large number in which there was a distinct improvement in the heart's action after the serum was injected.

(13) There is very little, if any, evidence to show that nephritis was caused in any case by the injection of serum. The number of cases of genuine nephritis is remarkably small, the deaths from that source numbering but fifteen.

(14) The effect of the serum on the nervous system is less marked than upon any other part of the body; paralytic sequelæ being recorded in 9.7 per cent. of the cases, the reports going to show that the protection afforded by the serum is not great unless injections are made very early.

The committee feels that this has been such a responsible task that it has thought best to state the principle which has guided it in making up the returns. While it has endeavored to present the favorable results with judicial fairness, it has also tried to give equal or even greater prominence to cases unfavorable to antitoxine.

In conclusion, the committee desires, in behalf of the society, to express its thanks to members of the profession who have co-operated so actively in this investigation, and to Dr. A. R. Guerard for the preparation of the statistical tables.

[Signed]

L. EMMETT HOLT, M. D.,	} Committee.
W. P. NORTHROP, M. D.,	
JOSEPH O'DWYER, M. D.,	
SAMUEL S. ADAMS, M. D.,	

The society voted to accept the report of the committee and after a full discussion it was decided to embody its conclusions in the following resolutions:

(1) Dose: For a child over two years old, the dose of antitoxine should be in all laryngeal cases with stenosis, and in all other severe cases, from 1,500 to 2,000

units for the first injection, to be repeated in from eighteen to twenty-four hours if there is no improvement; a third dose after a similar interval if necessary. For severe cases in children under two years, and for mild cases in those over that age, the initial dose should be 1,000 units, to be repeated as above mentioned if necessary; a second dose is not usually required. The dose should always be estimated in antitoxine units and not in the amount of serum.

(2) Quality of antitoxine: The most concentrated strength of an absolutely reliable preparation.

(3) Time of administration: Antitoxine should be administered as early as possible on a clinical diagnosis, not waiting for a bacteriological culture. However late the first observation is made, an injection should be given unless the progress of the case is favorable and satisfactory.

The committee was appointed to continue its work for another year and was requested to issue another circular asking for the further co-operation of the profession, this circular to be sent out as soon as possible, in order that physicians might record their cases as they occurred through the coming year.

**The Action of Thyreiodine in Obesity.**—Dr. Grawitz (*Münchener medicinische Wochenschrift*, 1896, No. 14; *Deutsche Medizinische Zeitung*, June 15, 1896) relates the cases of two women who were treated with thyreiodine for obesity. In one of them the use of the remedy was continued for only three days, at the rate of fifteen grains a day. During this period the patient lost three kilogrammes in weight, and this, says the author, was all the more remarkable from the fact that she took milk, butter, white bread, and eggs freely, although restriction in the matter of these articles before the thyreiodine was used had brought about only a very trifling loss of weight. An increased excretion of nitrogenous matter was evident in this case—to the amount of about four hundred and seventy-five grains—so that a decided loss of weight could not fail to result. There was, however, no increase of the fluid excretions, and the urine contained neither albumin nor sugar.

The other patient took fifteen grains of thyreiodine daily for three weeks, without any restriction of her diet, and she, too, lost three kilogrammes in weight. When she discontinued the use of the remedy her reduction of weight persisted for a short time, but she soon began to regain her flesh. Her subjective condition was not affected, and her urine was free from both albumin and sugar.

**Jaundice and Hæmaturia due to Quinine.**—Dr. De Robertis (*Raccogliatore medico*; *Deutsche Medizinische Zeitung*, June 15, 1896) relates the case of a patient who, after having had two paroxysms of malarial fever, took twenty-five grains of quinine in the course of a forenoon, in order to avert a third paroxysm. Toward evening he had a severe chill followed by high fever, headache, and cyanosis of the lips, ears, and fingers. His urine was reddish-brown and contained a good deal of albumin, blood pigment, and renal epithelium. Quinine was detected in the urine. On the following day the temperature fell, jaundice set in, and the liver was somewhat swollen and tender. In the course of twenty-four hours the urine was normal again. Two days later, when the patient was free from fever and almost wholly restored, he took twelve grains of quinine hydrochloride, in three doses. After a few hours he had another chill followed by fever and severe general symptoms. The

urine had the same character as before, and on the following day there was pronounced jaundice. This, then, says the author, was a case of icterico-hæmaturic fever due to the use of quinine.

**Hysterical Persons and the X Rays.**—In the *Nouvelles Montpellier médical* for April 25th, Dr. P. Bosc remarks that in several recent articles on the Röntgen rays the opinion had been expressed that the curiosities of vision observed in the hysterical might perhaps be due to their perceiving these rays. With this in view, Dr. Bosc examined a girl, fifteen years old, who was affected with hemianæsthesia and astasia-abasia, but whose vision seemed normal. Between the Crookes's tube and the girl's eye he placed a broad screen of two thicknesses of black paper. The light was obtained with a Holtz-Carré static machine. Under these conditions, neither he himself nor the girl's mother could see anything. The patient, on the contrary, saw very clearly, and with each eye separately, a light which she said was "like a lamp." As long as the current was passing she saw distinctly; as soon as it was interrupted she could see nothing. At the time of making the interruption Dr. Bosc kept up a production of sparks, so that the girl did not know that he stopped the current. He remarks that it was a curious thing that the girl's perception of light varied with the luminous intensity of the cathode rays, the tube being the same, which would seem to show that, always for the same tube, the production of Röntgen rays was in direct proportion to that of cathode rays.

**Potassium Permanganate in the Treatment of Gonorrhœa.**—Dr. M. Möller (*Archiv für Dermatologie und Syphilis*, 1896, No. 1; *Centralblatt für die gesammte Therapie*, June, 1896) has treated a hundred cases of gonorrhœal urethritis with Janet's injections of potassium permanganate. Some of them were acute, and others were chronic. All the patients were going about. Before the treatment was begun, the following questions were always considered: Whether gonococci were present or not, whether the urethritis was anterior or posterior, whether collections of gonococci existed within the urethra or outside of it, and whether or not the case was suitable for the employment of Janet's method. Great care as to the strength of the solution is to be recommended; one may begin with a 1-to-5,000 or a 1-to-4,000 solution, and then proceed to one of 1 to 1,500 or 1 to 1,000, according to the reaction and the tolerance. A definitive cure does not always coincide with the disappearance of the gonococci, but if, after an observation period of three weeks, after errors of diet, after soundings, etc., still no gonococci are to be seen, a definitive cure may be taken for granted. The method is not painless; in acute posterior urethritis these irrigations are very painful and not infrequently give rise to hæmaturia. Indeed, there are patients who refuse to submit to the treatment. There are cases in which, even after from fifteen to forty irrigations with solutions increased to the strength of 1 to 1,000, gonorrhœa may still be found; on the other hand, the method succeeds in some cases in which all other treatment has failed. The patient should be acquainted with the possible consequences of the treatment—pain, hæmaturia, and cystitis, together with the chance of not being cured after all. As an abortive method, in the first three or four days of the disease, it is better than any other; after that it is not of so much value; in subacute and chronic cases it is superior to other methods; used without due care as to the strength of the solution, it is not free from danger.

## Lectures and Addresses.

### THE PRESIDENT'S ADDRESS DELIVERED BEFORE THE AMERICAN LARYNGOLOGICAL ASSOCIATION AT ITS EIGHTEENTH ANNUAL CONGRESS.

By W. H. DALY, M. D.,  
PITTSBURGH, PA.

GENTLEMEN: The replete programme before us for this congress, comprising as it does thirty-four papers, not including the theses of the candidates for membership, assures us that it is quite possible to have for our organization a congress of the first class in a city of the second class.

I am most happy to see so many of the fellows present, and especially so to be able, through your hearty co-operation, to present such an extended programme of interesting papers—a programme that has never been equaled in the history of our honored society, and one which demonstrates that the fellows of the American Laryngological Association will attend a congress in other than metropolitan cities. It also serves to admonish me to be brief in my remarks to you this morning, that we may enter at once upon the work before us, and endeavor to do it full justice by deservedly calm, dignified, and learned discussion, of which you are so capable.

I am scarcely old enough to indulge much in looking backward, but I can not refrain from doing so, just a little, and with much pardonable pride, when contemplating the value our specialty has been and is to the general practice of medicine and surgery, as also the value of our literature to that of the general science of medicine and art of surgery, and the eagerness with which the latter is sought after and studied by the profession.

These are pleasant reflections, especially to those of us who began the study and practice of this work over twenty years ago, amid the doubts, the indifference, and even the disapprobation of our best friends, the general practitioners. And it is only by the exalted character and high standard of excellence of the work done that their respect has at last been won, and I sincerely hope their appreciation will be maintained by our continued and most deserving industry.

Indeed, I was also a busy general practitioner when, over twenty years ago, I began the study of laryngology, and I have never ceased to be somewhat of a general practitioner since, and I don't intend ever to cease my interest in general medicine and its practice, believing that one can not be a good specialist in diseases of the nose, ear, and throat without large experience and knowledge of general medicine. And I do not think that any one should ever begin our specialty until he has been a general practitioner from five to ten years or more.

As a matter of fact, I never in any way announced myself as a specialist in diseases of the nose, ear, and throat, but an enormous amount of the work came to me through my writings upon these subjects, and is still coming, in these my years of riper experience, and I hope of better judgment.

There is to me the highest sense of pleasure in knowing the respect that laryngology now receives from medical men as well as the laity, and that most of our teachings have stood the crucial test of time and practical experience, and have proved so great an aid to general medical science and practice. Indeed, the aid rendered by the laryngoscope and rhinoscope in skilled hands is now so universally conceded that to speak of it is almost trite. And there has been such substantial acknowledgment on the part of those in general practice that the men who do this sort of work mostly have multiplied enormously in number, and are well and fully equipped to aid their fellow-practitioners in the diagnosis and cure of cases, the obscurities of which can be so often revealed and made plain by the skilled employment of laryngoscopy and rhinoscopy.

I began this work twenty years ago in Pittsburgh, almost alone; now I am surrounded by dozens of capable men. I began it when there was scarcely a laryngoscope or rhinoscope in use by the medical profession west of the Alleghany Mountains, and indeed many otherwise intelligent medical men in this city at that time doubted my ability to make intralaryngeal examinations or topical applications of medicine to diseased parts within the larynx, and were disposed to joke about such pretensions as being chimerical. Now, in our more advanced state of knowledge, this seems difficult to believe, but it is none the less true.

One of the earliest cases of importance here, which attracted the attention of the profession, was that of a patient who was being treated for pulmonary emphysema (a dilatation of the pulmonary air cells), which was submitted to me for laryngoscopic examination and diagnosis. I was fresh from my London and Vienna pupilage, and easily demonstrated to my colleagues that the pulmonary condition was entirely due, not primarily to pulmonary emphysema *per se*, but to laryngeal stenosis, preventing the outflow of inspired air from the lungs. The obstructive disease was of a specific type in the larynx, and the fibrous adhesive bands, adhering to the false vocal cords, could be plainly seen with the laryngoscope. The patient was operated upon first, as a precautionary measure, by doing tracheotomy, after which the fibrous adhesive bands were removed by intralaryngeal operations, the larynx dilated, and the patient entirely cured in six months; he increased in bodily weight from one hundred and twenty to one hundred and ninety-one pounds, and resumed his labor as a steel roller in a rolling mill.

This case presents nothing strange to us to-day, but

at that time not only was it strange, but the conditions revealed by the laryngoscope were most surprising and interesting to all who observed them, and the results were brilliant and successful in the highest degree. In short, it was a triumph for laryngology.

In the matter of distinguishing whether aphonia is due to inflammatory processes or functional derangement, the laryngoscope is a most indispensable instrument, as every one is aware.

The influence of nasal obstructions, adenoid growths of the pharynx, and chronic amygdalitis upon the health of children merits a word.

There are so many robust men and women in this city to-day, of whom I had the professional charge in former years as puny, chicken-breasted specimens of childhood, with nasal obstructions, adenoid growths, and chronic amygdalitis, that I have thought it not amiss to advert to the real and permanent benefits derived from treatment for their removal, the results in every instance of which are so worthy of our best admiration.

I was accosted a few days ago by a stalwart young man, who smilingly told me that he was one who was placed under my care twenty years ago as a delicate boy, who weighed but sixty pounds when fourteen years old. He told me he had nearly doubled his weight in the two years succeeding his treatment, which consisted of the clearing out and curing of the adenoids in his upper pharynx, and the curing of a chronic amygdalitis. He is now a leading amateur athlete.

The debt that general medical and surgical science and art owe to laryngology and rhinology, then, is so apparent and real that we must be pardoned for our expression of honest pride for the part this learned and pioneer society has taken to place and maintain it on the high plane it now occupies. Let us then go forward in the right direction, and especially endeavor to further reveal the obscurities that still surround ethmoidal and sphenoidal diseases.

We have among our number the men of broad mind and ability who have already done much in this direction. All honor to Bryan, Bosworth, Mackenzie, Wright, and others, who have accomplished so much to make these intricate and obscure diseases plainer and more amenable to proper treatment.

Before closing let me voice a sentiment that all of us so earnestly feel, and that is, all honor to Manuel Garcia, one of the fathers of the laryngoscope and laryngology. Many of us sat with him last August, in London, around the banquet table of the laryngological section of the British Medical Association, and observed with pleasure how lightly and blithely his ninety odd years sat upon his silvered head, "frosty, but kindly." And now, with bowed heads and sorrowing hearts, we also feel all honor to the name and memory of dear Dr. Wilhelm Meyer, of Copenhagen, Denmark, whose death, after ripe years full of honors and loving regard by his

profession, we justly mourn. He first taught us the presence of and cure for pharyngeal adenoids.

Shall we ever forget his fatherly wisdom and kindness to us in Copenhagen, in August, 1884? And now that all Christendom is uniting to erect a monument to his memory, let us at this meeting, one and all, give with a liberal hand toward its erection, thus showing in a practical way what every one has so honestly felt in his heart.

Now, dear friends and fellows of the American Laryngological Association, I bid you a hearty welcome to this busy and, we think, very attractive city.

We are but a small band of workers, who have come to unravel scientific questions in this busy hive of mechanical industry. That we will do our best in a most intelligent manner our past history guarantees. I am sure that at the close of this meeting you will all be pleased with the work that you have done.

As the rich plains of Italy were held out to the soldiers of France as an inviting field for their bravery and conquest, so you have in the more peaceful and gentle field of science of your specialty a programme here before you, prepared by your able fellows, that is a field rich in promise of interest, profit, and pleasure. So again I bid you thrice welcome.

And I now declare this the eighteenth annual congress of the American Laryngological Association open for work.

## Original Communications.

### THE FUTURE OF MEDICAL COLLEGES IN THE SMALLER CITIES OF THE UNITED STATES.\*

By DANIEL MORTON, M. D.,  
ST. JOSEPH, MO.

THERE are two marked principles that are governing the medical profession to-day, in dealing with the subject of medical education. They are as follows: First, a diploma should confer no right to practise medicine. Second, every student entering upon the study of medicine should have a thorough preliminary education. What effect will the enforcement of these principles have upon the smaller medical colleges of the Union? This is the question proposed for discussion in this paper.

A backward glance at the beginning of a movement and a little study of its subsequent progress will often enable one to forecast its future with a considerable degree of certainty.

In the early history of America, medical aid was often rendered by men who had never attended a medical college. Graduates from the mother country were not sufficient to supply the demand. The first school in America, the College of Medicine of Philadelphia,

\* Read before the Kansas State Medical Society, May 14, 1896, at Topeka, Kansas.

now the Medical Department of the University of Pennsylvania, was not founded until 1765.

From this institution was graduated, in 1768, Dr. John Archer with the degree of Bachelor of Medicine, the first medical degree ever conferred in America. In the same year in New York city was organized the Medical Department of King's College, now the College of Physicians and Surgeons, the Medical Department of Columbia University. It has been estimated by Dr. Noah Davis that at the time of the Declaration of Independence there were in the thirteen colonies three or four thousand practitioners of medicine supplying the three million inhabitants with medical aid. About four hundred only of these practitioners had received the degree of M. D. In 1810 there were five medical colleges in the United States. Students were apprenticed to a regular practitioner for two or four years, the degree of M. D. being conferred after attendance at two subsequent college terms. Some entered practice at the end of one college term, and some at the end of their apprenticeship without having attended college at all. And now medical colleges in America began to multiply with increasing rapidity as the years went on, until their number greatly exceeded the actual demands of the situation.

From 1840 to 1890 there was a perfect craze for establishing medical colleges, and the competition for students became so severe that entrance and graduation requirements were reduced to a minimum.

During the fifty years between 1830 and 1880 medical education in the United States failed to keep pace with the advance made in the same line of work in other countries. Although a vast quantity of knowledge had been accumulated since the beginning of the century, two years of instruction still remained the length of the medical course, just as it had been in 1810, and this too at a time when European countries were requiring four, five, and six years' study of their medical graduates. This statement should be modified by mentioning the adoption by the Chicago Medical College, in 1868, of a three years' graded course.

The diploma opened the door to practice; and as long as it did this, it remained a commodity to be first manufactured at the lowest possible cost by the manufacturer (the medical college), and then to be purchased in the open market by the consumer (the medical student) at the least outlay in money and time. At the end of our first century of existence Dr. Noah Davis thus describes the American medical educational system as it had grown up under the principle of giving to the diploma a licensing power. (See quotation at end of paper.)

Having now sketched the condition of affairs as they have existed in the past, we are prepared to appreciate the efforts made to correct the abuses which had grown up as a result of this "freest rivalry" among medical colleges.

All laws governing medical practice are based, first,

upon the recognition of the diploma as a legal license; and second, upon denying this right to the diploma, and requiring an examination of every applicant at the hands of a civil board of medical examiners.

The first-named law, known as the "Diploma law," gives the right of college supervision to the State Board of Health. This supervision is exercised by establishing a "Schedule of Minimum Requirements," which schedule requires all medical colleges, large or small, to make the course of lectures extend through a specified number of months, to furnish specified laboratory facilities, to furnish a specified amount of dissecting material to each student, etc.

In this way are the medical colleges made amenable to the civil authorities. With the teaching requirements thus laid down every college must comply to secure recognition of its diploma. About the year 1880, for the first time in the history of the country, the Illinois board, under the leadership of Dr. John H. Rauch, began to vigorously use this power. It published a series of reports that have been the basis of all subsequent work having for its object the legal control of medical practice in the United States. I can not enter into a detailed history of the good accomplished by the "Diploma law." Suffice it to say that its effect has been most salutary. In my own State it is this law which is in force, and it is executed by a board of fearless men who are doing a great work in checking the abuses which have so long run riot in our midst. The great flaw in it is the fact that it after all delegates the licensing power to the faculties of the medical colleges. This is not true of a law requiring every applicant for license to stand an examination conducted by a board of medical examiners. Let us not digress, however, but return to the minimum requirements and discuss the effect of the enforcement of some of them upon the smaller medical colleges, and the ability of the medical colleges to comply with others.

**PRELIMINARY EDUCATION.**—The great tendency of the profession to-day is to demand a thorough preliminary education of every student entering upon the study of medicine and to permit none to matriculate who do not have it. For many years any one who so desired could enter a medical college without regard to preliminary English education. Many matriculates had the merest rudiments of a common school education, and many more were lacking even in this. This statement can be easily substantiated by looking for a few minutes at the prescriptions on file in the drug stores, or by the revelations of one day's mail at the office of any State medical officer like that of the secretary of the board of health. Men who could not enter other callings in life because of their lack of education found the doors of medicine wide open, with no obstacles thrown in the way to those desiring to enter. Engineers, harness makers, hostlers, and men of like station in life desiring to become doctors were readily accommodated by medical colleges.

I would not cast a slur upon these occupations, for I believe that work is honorable in all, and laziness is a reproach wherever found. But no one has a right to assume the grave responsibilities of a physician's calling unless he has qualified himself to do so. Granting for argument's sake that there was at one time a warrant for such a custom, it is certainly true that that time has passed, never to return. The advance of science has been too great to be appreciated by one who can barely put himself in communication with the everyday affairs of life as published in the daily papers. What can such a man do with a scientific treatise on physiology or therapeutics, studies involving a presumption of knowledge of physics and chemistry and the ability to think and reason accurately, to properly observe phenomena, and to draw therefrom the proper conclusions? One must know addition and subtraction before one can solve problems in multiplication and division. On account of the uneducated students who flock to the medical colleges, the latter have, in some instances, established chairs for teaching Latin and elementary chemistry and physics. They thus convert themselves into a sort of medical-literary college, and I have wondered sometimes why they did not at the same time confer both the degree of M. D. and the degree of A. M. The uneducated student goes to the college in the smaller city or to the low grade one in the large city. There he often finds teachers as ignorant as he. I have known graduates of a medical school to become in a few months professors in their Alma Mater. When a high, uniform standard is established for preliminary education this class will be unable to measure up to it. They will then either give up the study of medicine and take a station in life commensurate with their attainments, or they will set about correcting the defects of their education so that they may, when this is done, enter a medical college.

Students who have received a good literary education seek a good medical college. Knowing what a good literary education is, they will not be content with a poor medical one. So that either way the knife cuts into the medical college of the small city. The uneducated student can not matriculate and the educated one will not. The result is inevitable—lessened attendance and lessened income. In Missouri the State board ruled out about a hundred students in the various colleges of the State because of lack of preliminary education. This was for the session of 1895 and 1896, acting under the ruling of an examination by the county superintendents of public instruction. This method has proved unsatisfactory, for nearly all of this number have since been reinstated. For the session of 1896 to 1897 matriculates must have diplomas of graduation from a literary or scientific college or high school, or in lieu thereof pass an examination before the State superintendent of public schools.

**DISSECTION.**—It is with the greatest difficulty that the smaller colleges secure subjects for dissection. If there were not more students than necessary the anatomical

law would supply the demand. It was never intended that every city of fifty or sixty thousand people should have two or three medical colleges. But the colleges must have the subjects or the State board won't recognize them. What is the result? The anatomical boards can't supply them, and we see a Topeka Medical College close its doors temporarily; we see a widow suing a St. Joseph Medical College, charging the school with the theft of her husband's body; we see nineteen medical students arrested at Des Moines, Iowa, on the charge of grave-robbing. There is little encouragement to smaller schools if the teaching of the very foundation study of medicine is attended with such hazard.

**LENGTH OF TERM.**—By establishing a uniform length of term another blow has been struck at the smaller schools. They have heretofore said to the student: "Come to us; a diploma is what you want. We will graduate you in two years. Why go to a school that requires three? Our term is only five months long; why do you want to study six? Our fees are one third those of the larger schools. You can board in our town for three dollars a week; why go elsewhere and pay five?" But when every school in every city must give a course of equal duration one of the great inducements of the smaller medical college is gone.

**CLINICS AND HOSPITAL ATTENDANCE.**—In a recent article entitled *The Necessities of a Modern Medical College*, Dr. Ingals says: "The advantages that were considered ample until recently can not now be accepted. Every college must therefore be provided with dispensary rooms and hospital accommodations. I am familiar with the fact that fifty years ago a first-class medical college could be conducted with very little clinical material, but it does not seem practicable to give the instruction requisite at the present time with less than four or five thousand outdoor patients annually, and hospital facilities of less than seventy-five or a hundred beds." How many of the smaller colleges can measure up to this minimum requirement? How many cases of obstetrics do their graduates attend before receiving a diploma? Do their graduates have sufficient hospital experience to acquire a knowledge of the grave diseases affecting men? If they have all these things, why in the name of Heaven do their graduates pack their grips and start for a large school in a large city?

And thus I might go on enumerating many other points in which the smaller school works at a great disadvantage, under a uniform standard of requirements; but I will not weary you; I merely mention chemical, bacteriological, histological, and pathological laboratories and the expense of their proper equipment and maintenance, which can not be obtained from the tuition fees.

Let us now consider the effect upon these schools of a law requiring a State examination of every graduate from every school. Will this examination be more difficult than the school examination? Undoubtedly it will. The examinee when at school has opportunities to be-

come acquainted with the hobbies of each teacher. It is a well-established fact that every teacher has special questions and special subjects that play an important rôle in his examination. These individual preferences are handed down by tradition from one class of students to the succeeding one. Special stress laid upon certain subjects during the winter's course by the teacher are sure pointers of future examination questions. Students and quiz masters are quick to pick up these hints. How common it is toward the end of a session for students, with or without the help of a quiz master, to "bone up" on studies for examination! When the final test is made, many of the questions asked in the trying ordeal are found to be the ones expected and looked for. In fact, one of the strongest inducements held out to students by quiz masters is the knowledge which the latter possess of the individual peculiarities of the teacher's views on medical subjects taught by him, and a list of the questions which have been asked on examinations for many years perhaps. Any one who has looked over such a list has been struck with the striking similarity of the questions asked and with the appearance at certain intervals of well-known ones. The disadvantage under which a student labors who takes the senior year in another college from that in which his first courses were taken is thoroughly well understood, and is only another proof of the truth of the above assertions. In other words, each college has an examination that in character, questions asked, standard required, and other characteristics is *sui generis*. These things are not true of a State examination. The questions are broader in scope, because they are prepared from a study not only of medical college examination papers, but of many State examination papers. Go to the students who must pass a State as well as a college examination and ask them which they fear the most. They will answer, the State examination, and cite as a basis of their dread the reasons mentioned above, or others of a like character. There is every inducement on the part of a State board to keep the grade of its examinations high, so that incompetent men may be kept out of the State. If it establishes a grade lower than that of its neighboring States the State over which it has jurisdiction at once becomes the dumping ground of those who have failed to obtain a license elsewhere.

There is every inducement for the medical college to make its examinations easy, especially if it be an undowered institution, dependent upon students' fees for existence. The tendency of one is up, the tendency of the other is down. When a student knows that after his medical college life is ended there is an examination to be passed at which he has no "under holds," at which he must prove the possession of medical knowledge sufficient in amount to entitle him to be trusted with the lives of his fellow beings, and that, too, before a tribunal impartial and impersonal, what will be his course? He will at once see that nothing but the possession of sheer

knowledge will be of avail, and he will set about seeking a place where this can be best obtained. Will he find it in the medical college of the small city? I believe not. A diploma carrying with it the licensing power is the stock in trade of these medical colleges. Do away with licensing power and you have done away with the only inducement it has to offer, and students desiring a medical education will go elsewhere. Do away with students and you do away with the food which gives the college life. Inanition and death follow. The diploma law is gradually being replaced with the State examination law. There are now twenty-two medical examining boards in the United States recognizing no diploma as a license. When all the States shall have fallen into line the smaller medical college as a degree-conferring body will become a thing of the past.

Having to compete with the superior advantages of the larger colleges on the one hand and constantly subjected to the prodding of the State board on the other, deserted by those students who recognize that such a college can not fit them for a State examination, drawing their supply of students from a territory ever diminishing in size because of the encroachments of medical practice laws upon States heretofore having none, so situated that it is absolutely impossible for them to comply with the ever-increasing demands of the profession for a higher education, and having to meet these demands with an ever-diminishing income produced by the lessened number of students, it does look as though the future of the medical college in the smaller city is dark and dreary.

If, then, all these things are true, what will be the future of the medical college in the smaller city? The handwriting is on the wall, and Mene, Mene, Tekel, Upharsin does not require the aid of a prophet for interpretation. At no far distant day a diploma will have one significance and one significance only. It will indicate that the holder has complied with the prescribed course of the institution granting it, and it will be a preliminary to the State license. The medical college of the future will be compelled to regulate its teaching by requirements of the civil licensing power. It will stop trying to do something it can not do. We have reached the high tide in medical college creation. There will never again be as many medical colleges. They will lessen in number but improve in quality with every succeeding year. Cities that are capable of sustaining one good medical college will see the three or four now existing merged into one institution capable of doing good, thorough, honest work. Others still will cease to be degree-conferring institutions, but will correlate themselves with colleges in larger cities where ample facilities for teaching the senior classes are found. They will find a legitimate sphere of usefulness in teaching the primary branches of medicine and then passing the student on for final instructions and for the degree to a degree-conferring school in a large city.

Colleges so situated as to be unable to comply with the ever-increasing demands of the civil medical authorities will become extinct. When this condition of affairs is brought about we shall see medical colleges receiving endowments. With these endowments will come larger teaching facilities and larger facilities for original research. As a result of the former will come a highly educated profession who will use the discoveries of the latter to lessen the woes and sufferings of the human race.

I trust that this paper will leave upon your minds the abiding conviction that a medical examining law is superior to every other form of enactment having for its object the legal control of medical practice. I hope that Kansas in this, as in everything else, will prove herself in the line of progress. I hope that she will place no "mossback" law upon her statute books.

"Under these conditions and tendencies, by the end of the second thirty years of our history the number of medical colleges had increased from five to forty-one; the number of students attending them, from six hundred and fifty to twenty-five hundred; and the ratio of those graduating each year, from less than one in six to one in three.

"Here we see a system of medical colleges originating spontaneously to supply the wants of a free and rapidly increasing people, and open to the most unrestricted rivalry, actively developing two apparently opposite results. In one direction the schools properly vie with each other in increasing the number of their professors, in full consonance with the rapid advancement of the medical sciences; they sagaciously seek out and enlist the services, as teachers, of the most learned, eloquent, and industrious men to be found in the profession; they spend time and money freely in filling laboratories, anatomical rooms, and museums with all the means for efficient teaching and illustration. So far their free rivalry has reference only to their office as teaching bodies, institutions for imparting instruction, and is productive of nothing but good to the profession and the people. But the anomaly consists in the fact that, at the same time they were increasing their professors, the same institutions were rapidly shortening their annual courses; cutting off all collateral requirements; failing to grade the branches of medical study as they increased in number and extent, so as to adapt them to the several years of pupillage; and even reducing the final examination to the simple process of asking a few oral questions in the mysterious 'greenroom.'

"This most unfortunate tendency of our experiment in permitting the freest rivalry in the establishment of medical schools results directly and necessarily from the fact that the degrees they confer and the diplomas they give have been permitted throughout the whole country, with only a few temporary exceptions, to have all the force and effect of a license to practise medicine. It requires but a moderate familiarity with the motives that govern human actions to see clearly that in a country where there are no entailments of estates, and where the great body of young men who seek the professions are without pecuniary fortunes, and largely dependent on their own industry for the means of education as well as reputation and fortune in after life, the question, 'Where can I get the degree of doctor, which is equivalent to a license to practise and a full admission into the ranks of the medical profession, in the shortest time,

and consequently with the least expenditure of time and money?' exerts a very great if not controlling influence in determining where the student shall attend his college instruction. Not that medical students are a whit less conscientious in their desire to fully qualify themselves for the responsible duties of our profession than those who seek any other calling in life; but present necessity, or even convenience, easily controls when there comes with it the flattering thought that, at another time, after having earned a little money by practice, all deficiencies can be supplied by a season of reviewing in a school of the largest facilities.

"Just on this half-unconscious delusion, hundreds are induced to go where the requirements in time and money are least, regardless of all other advantages. The medical college in a country village, remote from all facilities for clinical instruction in hospital or dispensary, and but scantily supplied with subjects for dissection, can issue to its graduates just as large a diploma, couched in just as unintelligible Latin, and having much the same influence with the people as the school in a metropolitan city whose students can have the largest facilities for clinical and practical study. Hence it is not strange that, before the end of the seventh decade of the past century of our existence as a nation, about forty medical colleges had been organized, only sixteen of which were so situated as to afford their students any proper facilities for clinical instruction; and that those sixteen were resorted to by a little more than one third of the whole number of those who attended medical colleges.

"The general acceptance of the college diploma as full admission into the profession, thereby uniting in the hands of the same men the business of teaching and the power of licensing, has continued to the present day. It is wholly responsible for the fact that, while we have sixty-four medical colleges to-day (1876), one third of them are so located that they can afford their students no advantages for clinical instruction worthy of mention; and all except three or four still attempt to crowd instruction in all the departments of medicine upon the attention of mixed or ungraded classes, in annual college terms of from sixteen to twenty weeks, and exact only two such strictly repetitional courses for graduation.

"This state of things, in regard to our medical schools, is made still worse by the fact that, during the century under consideration, the system of private medical pupillage has undergone a complete change. At the beginning of that period, as we have already seen, the private study under a master was a protracted and serious work, and the resort to the college was simply to review and more fully illustrate that work; but steadily, as medical colleges increased in number, as population became more dense, and as steamboats and railroads increased a thousandfold the facilities for travel, the work of private pupillage relaxed. Indentures of medical students, as pupils, to the more noted practitioners long since ceased, and the relations of student and preceptor have become merely nominal in practice; in nine cases out of ten consisting in little more than the registry of the student's name in the doctor's office, permission to read the books of his library or not, as he chooses, and the giving of a certificate of time of study for the student to take to the medical college where he expects to graduate."—*Contributions to the History of Medical Education and Medical Institutions in the United States of America, 1776-1876*. # A CASE OF RENAL PHTHISIS COMPLICATING PULMONARY TUBERCULOSIS.\*

By HERBERT MAXON KING, M. D.,  
GRAND RAPIDS, MICH.

MR. PRESIDENT AND GENTLEMEN: Transient albuminuria intervening in the course of pulmonary tuberculosis is a most frequent and trivial complication which need neither occasion alarm nor necessitate any change in the mode of treatment, since, as a rule, it is either simply an evidence of the impaired nutrition of the renal epithelium or the result of the periodic pyrexia. Even that degree of renal congestion marked by the presence in the urine of albumin, small hyaline casts, and cylindroids, appearing at intervals in the course of the disease, is not an alarming or infrequent complication of phthisis and can not of itself indicate any serious disturbance of the integrity of the kidneys.

But a persistent albuminuria appearing after the development of tuberculosis in the lungs, attended with an increased pyrexia and less marked remissions, rigor, polyuria, dysuria, and especially pyuria to a greater or less degree, should always excite the keenest apprehension and vigilance. For these are unmistakable signs of nephritis, a condition grave enough in itself, to be sure, but doubly so when occurring as a complication of pulmonary phthisis.

Intervening in the later stages of pulmonary tuberculosis, or in the course of an acute general tuberculosis, nephritis only hastens the inevitably fatal termination, and its recognition in such cases is a matter of little moment to the patient and, aside from gratifying scientific zeal, of little practical value to the physician.

But, appearing as it sometimes does early in the course of the pulmonary disease, when but a small portion of the lung is involved, I can not but think that its recognition is the means of occasionally saving life, or at least of prolonging it.

Nephritis in a tuberculous patient whose kidneys have before been healthy must almost of necessity be either a renal phthisis due to direct infection through the lymph channels (or possibly the circulation?) or an interstitial nephritis due to prolonged disturbance with the nutrition of the kidney cells. The case which I desire to present to you this evening is a type of the former, one of unmistakable tuberculosis of the kidney; its interest lies mainly in the microscopical appearance of the urinary sediment, in which absolute proof of the nature of the existing lesion is demonstrable by the presence of the tubercle bacilli in characteristic arrangement.

Tuberculosis of the kidney occurs in two distinct forms: (a) acute miliary tuberculosis, and (b) local

caseating tuberculosis or scrofulous kidney (Purdy). The former is twice as frequently met with as the latter, according to the above-quoted authority, and hence renal phthisis is not a condition often met with, especially in private practice.

I find upon a careful *résumé* of the last fifty cases of tuberculosis occurring in my own practice that I have seen three in which renal phthisis was a complication. I have been able to demonstrate the presence of tubercle bacilli in the urinary sediment in two of these, including the case which I present to you to-night. The third instance of this condition yielded to treatment\* before there was breaking down of the involved tissues, and the specific bacillus has presumably not been present in the sediment, although the case is still under close observation. Even when the bacilli do exist in the urine, as shown in the development of cultures inoculated from such urine, Purdy states that it is very difficult to demonstrate their presence from cover-glass preparations of urinary sediment. Vierordt, however, says it is as easy to demonstrate their presence in the urine as in the sputum. I have not found it so in my experience, and for obvious reasons I should think it would always be a much more difficult matter.

The case which I wish to present is that of a woman, thirty years of age. In the family history it develops that one sister died from acute tuberculosis at eighteen years of age, and one brother has shown evidences of incipient disease at the apex of one lung. Parents and grandparents free from tuberculosis in any form. The patient has been married seven years, in which time she has borne five children, all apparently healthy, the last being, at the time of examination (February 17th), seven weeks old. Cough and emaciation date from about one year ago. She was, however, much better during pregnancy, only to grow rapidly worse after parturition.

Subjectively, cough and expectoration, occasional night sweats, anorexia, and general loss of strength are the only distressing symptoms. It is worth remark that at no time in the history of the disease has pain, either in the region of the kidneys or upon micturition, been present.

PHYSICAL EXAMINATION, 2 o'clock, P. M.—Pulse, 125, regular and fairly strong. Temperature, 102° F. Inspection discovers marked emaciation, depressed infraclavicular spaces on both sides, with considerable loss of expansion at right apex. Palpation discovers increased vocal fremitus at right apex. Percussion: Dullness marked at right apex; much less, though slight, dullness at left apex. Auscultation: Cavernous respiratory sounds, moist and dry râles, and increased vocal resonance at right apex. "Roughened" respiration at left apex. Posteriorly, diminished vesicular murmur at base of right lung. Examination of the blood by Thoma-Zeiss cytometer gives an average of 3,975,000 red corpuscles to the cubic millimetre; by von Fleischl's hæmometer, fifty per cent. of normal hæmoglobin. Microscopically, numerous poikilocytes present. (It is interesting to remark the discrepancy between the numerical value of the blood and the amount of hæmoglobin pres-

\* The hypodermic administration of nucleinic acid solution in doses averaging a hundred minims daily.

more interesting specimen, one of the urine sediment, containing bacilli tuberculosis, and accordingly the pathognomonic sign of the existing condition. It is

FIG. 2.

stained by the same process as the sputum and demonstrates the bacilli, in several fields, in an arrangement similar to that met with in pure cultures, which, accord-

FIG. 3.

ing to Vierordt, Purdy, and others, is characteristic of this condition, and it would be quite impossible to confound them with the smegma bacilli of the healthy urethra. By aid of an improvised camera lucida I have made a sketch of one field which after long search I found best illustrated this arrangement of the bacilli,

and this I also beg to present as perhaps showing this peculiar arrangement better than the field now under the microscope (see Fig. 1).

In conclusion, the lesson taught us by such a case may be worthy of note. In the first place, the urine from a phthisical patient should be subjected to frequent and rigid examinations, and more particularly in cases where the rigors, pyrexia, and prostration are out of proportion to the extent of the apparent lesion. In this connection I would ask your attention to the two clinical charts. The first (Fig. 2) is that of a patient suffering from fully as great a pulmonary involvement as is the case reported, and the temperature and pulse I regard as typical of the generality of such cases. The second (Fig. 3) is a chart from the case reported. The departure from the rule in this would, of course, excite our most lively suspicions.

Finally, vigilance should not be relaxed because of absence of subjective symptoms pointing to renal complications, which, as I have shown, may progress to an advanced stage without any symptoms which would indicate the nature of the complication.

86 JEFFERSON AVENUE.

#### A CONTRIBUTION TO THE STUDY OF ACUTE ASCENDING (LANDRY'S) PARALYSIS.

By PEARCE BAILEY, A. M., M. D.,

ASSISTANT IN NEUROLOGY, VANDERBILT CLINIC;

ATTENDING PHYSICIAN TO THE  
ALMSHOUSE, WORKHOUSE, AND INCURABLE HOSPITALS, NEW YORK,

AND JAMES EWING, A. M., M. D.,

TUTOR IN HISTOLOGY, COLLEGE OF PHYSICIANS AND SURGEONS,

COLUMBIA UNIVERSITY, NEW YORK;

ASSISTANT PATHOLOGIST TO ROOSEVELT HOSPITAL.

(Concluded from page 10.)

Thus it appears from the forty-two cases cited that fatal acute ascending paralysis may be associated with any one of four conditions, which may be classed as follows:

1. Cases in which no histological changes were demonstrated in the nervous system.
2. Cases in which there was an acute exudative inflammation of the cord and medulla, and sometimes of the brain.
3. Cases in which there was an acute inflammation of the peripheral nerves.
4. Cases in which there was an acute inflammation both of the central and peripheral nervous systems.

1. *No Changes Found.*—After careful consideration of the cases in which no lesion was found in the nervous system, we consider it a matter of considerable doubt whether this same negative result would have been reached if the present accepted methods of examination had been applied. In six of the sixteen cases in Group I the peripheral nerves were not mentioned or not examined. In only two is it stated that the nerves were examined in osmic acid. Furthermore, in none of these cases were the most improved methods for the study of

cytological detail employed. It is entirely possible that Nissl's stain might have revealed lesions in the ganglion cells which, examined by cruder methods, failed of demonstration. In spite of these objections to the methods used, the examinations were conducted by skilled investigators, and a long series of examinations, with uniformly positive results, will be necessary before it can be postulated that fatal acute ascending motor paralysis can not exist without demonstrable changes in the nervous system.

2. *Changes in the Cord only.*—Of the fourteen cases from Group II, (a), in which well-marked changes were found in the cord alone, in nine the peripheral nerves were not examined; in only one of these were the clinical symptoms of neuritis present. The remaining five cases conclusively demonstrate that a lesion limited to the cerebro-spinal axis may produce acute ascending paralysis. Moreover, here must be added four of the cases reported as anterior poliomyelitis, in which the pathological changes were the same as those found in the cases of Group II, (a), and in which the symptoms were typical of acute ascending paralysis. There is, therefore, a total of eighteen cases in which distinct lesions were found in the cerebro-spinal axis alone.

3. *Nerves only Affected.*—The changes of peripheral neuritis alone were satisfactorily demonstrated in one of these four cases in Group II, (b). In Hun's case degeneration of nerve fibres was found in the anterior roots of the cauda equina only. Such a lesion being entirely inadequate to cause death, this case might equally well have been placed with those in which no lesion was found. It is impossible to say from Putnam's report whether or not the cord was involved as well as the nerves, as it is not stated in his article that the cord was examined. Thus there is only one case from Group II, (b), to show that a lesion limited to the peripheral nerves may cause typical symptoms of fatal acute ascending paralysis.

Notwithstanding the contrary conclusions reached by some other observers, our plan of classification, necessitating a complete clinical adherence to acute ascending motor paralysis and a satisfactory pathological examination, has prevented us from including any further cases in this category.

If these cases of peripheral neuritis are to be associated with those of anterior poliomyelitis under the term of Landry's paralysis, such a classification can only be justifiable by the modern conception of the neuron.

With only a single element, the secondary motor neuron between the cortex and the anterior horns of the spinal cord, and the primary motor neuron between the anterior horns and the periphery, the distinction between peripheral and central changes of the nervous system has become less sharply definable.

So the cases of Landry's paralysis, in which pathological changes are found chiefly in the nerve trunks, may be explained by the assumption that the effects of

the disease were chiefly in the primary motor neuron; and, although the irritation acted originally on the protoplasmic portion of the neuron, those portions of the neuraxons farthest removed from the nutrient protoplasm showed the most evident results of the action of the toxic agent.

The same explanation may hold good for the primary motor neuron, although no cases have as yet been examined with sufficiently delicate methods (e. g., Marchi's) to detect degenerations in the neuraxons of the cortical cells.

4. *Changes in Cord and Nerves.*—Only three of the cases from Group II, (c), can with complete accuracy be placed in this class; but, from the fact that in Centanni's case bacilli are reported in considerable numbers in the nerve sheaths (a most unusual occurrence), we have thought best to classify that case among those showing changes in both cord and nerves. To this class also rightly belong one case reported by Rissler and one by Redlich, detailed in Group III, and originally described as acute anterior poliomyelitis. In these the symptoms were typical of acute ascending paralysis, and pathological changes were found both in the cerebro-spinal axis and in the peripheral nerves.

It will be seen from the foregoing summary that there is a total of twenty-eight recorded cases of Landry's paralysis in which lesions were demonstrated either in the central nervous system alone, or in the central and peripheral nervous system.

But few bacteriological examinations in any of the preceding cases have been made. Eisenlohr (Group II, (c)) found the *Staphylococcus pyogenes aureus* in all organs, and the *Staphylococcus cereus* (Passet) in the spleen and sciatic nerve. Curschmann found bacilli in the white substance of the cord, which he professes to have demonstrated (by inoculations in rabbits) to be the typhoid bacillus. Giusetti cultivated a chromogenic bacillus from the cord and sciatic nerve. Centanni saw small bacilli in the sheaths of the peripheral nerves. Oettinger and Marinesco demonstrated cocci in the ganglion cells, in leucocytes, and in the tissues around the central canal. Remlinger isolated, with careful technics, a pure culture of *Streptococcus longus* from the spinal cord. Inoculation of rabbits from the tubes was without effect. Partial bacteriological examinations in four other cases were negative.

Although conclusive demonstration is wanting, a consideration of the ætiology, symptoms, and pathology of this disease points toward the action in the body of some toxic agent, in many if not in all cases of bacterial origin, as the direct cause of the lesion. In support of this belief we may refer to the occurrence of lesions identical with some of those described above in epidemics of anterior poliomyelitis (Medin, *Verhand. d. X. inter. Cong.*, vol. ii, 6, 37; Cordier, *Lyon med.*, 1888, lvii; Caverly, *Am. Med. Jour.*, 1896, xxi, p. 1). Also Bristowe and Horsley (*Brit. Med. Jour.*, 1888, vol. ii, p. 1110) report a case of

typical ascending paralysis, without detailed autopsy, due to undoubted rabies.

Finally, Thoinot and Masseline (*Rev. de méd.*, June, 1884) have succeeded in producing symptoms of spinal paralysis in rabbits by intravenous injections of *Bacillus coli communis* and of *Staphylococcus pyogenes aureus*.

The lesions, as detailed in the foregoing tables, are those of an intense acute exudative inflammation of a character such as is usually dependent on a bacterial cause. The condition of the abdominal viscera points distinctly to an infectious element in the local process. If we are to accept the negative pathological reports collected in Group I, the symptoms in such cases may be most reasonably explained by the presence in the circulation, and especially in the region of the central nervous system, of a toxic agent which destroys nervous function without causing demonstrable histological lesion.

From the limited data it has been impossible for us to distinguish any differential clinical signs from the various classes. While most cases associated with extensive pathological changes bore the clinical stamp of infectious disease, in some with negative pathological report this feature seemed equally pronounced. Again, sensory changes indicative of neuritis were present in cases in which the nerves were found to be normal, as well as in those in which neuritis was demonstrated. Marked febrile disturbance was not prominent in any of the cases, but occurred in isolated instances in all classes.

The application of electrical tests seemed of no assistance in determining the pathological condition.

While it is not to be expected that the bladder and rectum should be paralyzed in lesions limited to the peripheral nerves, these functions may equally well remain unaffected if the lesions of anterior poliomyelitis are but slightly marked in the sacral region. Other clinical data were equally lacking in differential value. In the table on symptomatology may be found a review of the symptoms as they occurred in the various groups.

The conclusions from the present study may be summarized as follows:

Acute ascending paralysis is an acute toxæmia in which the poisonous agent affects chiefly the nervous system.

The commonest seat of the lesion is in the spinal cord and in the medulla, and it may be present in the cortex and in the nerve roots. When in the spinal cord the lesion is that of acute anterior poliomyelitis—namely, an acute exudative inflammation, following the distribution of the central branch of the anterior spinal artery, with cellular infiltration of the circumvascular sheaths, degeneration of ganglion cells, loss of structural elements, and with or without degeneration of the anterior roots. The lesions in other parts of the cerebro-spinal axis are of a similar nature.

The evidence that the lesion of typical Landry's paralysis may exist in the peripheral nerves alone is based

upon a single case reported twenty years ago by Dejerine. When the lesion affects the peripheral nerves there are increase of neuroglia cells and degeneration of nerve fibres.

It is at present impossible to deny that acute ascending paralysis may run a fatal course without leaving demonstrable histological changes in the nervous system. It is certain that the cases with negative pathological report did not present the marked vascular lesions of acute anterior poliomyelitis, but it seems probable that in these cases there were changes in the ganglion cells demonstrable by delicate methods. From the present data it seems to us impossible to distinguish by the clinical symptoms the different types of lesions.

The investigation of the present case was conducted in the pathological laboratory of the College of Physicians and Surgeons. For kind revision of the paper we are greatly indebted to Professor T. Mitchell Prudden and to Professor M. Allen Starr. Our thanks are due to Dr. Hodenpyl, pathologist to Roosevelt Hospital, for the opportunity of reporting the case.

## SPINDLE-CELLED SARCOMA OF THE NASAL PASSAGE.\*

By J. E. BOYLAN, M.D.,

CINCINNATI.

IN view of a somewhat more hopeful prognosis which accumulating reports of sarcoma of the nasal passages seem to hold out, I wish to add the following case to those already recorded:

In July, 1894, Mr. P., aged forty-five years, of Coburg, Canada, suffering from obstinate nosebleeding, was seen by me with his family physician. The bleeding, which had become of late severe, had occurred frequently during a period of several months, and had twice proved difficult to check. On a recent occasion, while hunting in a canoe, he had an attack which was so prolonged that he became very weak from loss of blood before it could be arrested. He had further suffered from stoppage of the nose and occasional acute pain in the head for nearly a year.

At the time of introduction, he presented an abnormally broad and flattened nose, somewhat irregular in shape, owing to a noticeable bulging on the left side under the margin of the nasal bone. There was some slight oozing of blood from the nostril, and, upon compressing the opposite side, the left passage was found to be totally occluded. Closer examination revealed the following: Upon tilting up the tip of the nose, an irregular brown-red mass at once became visible, filling in the cavity almost to its anterior opening, being quite soft to the touch, and bleeding freely upon contact with a probe. Posterior rhinoscopic examination, which was quite practicable, disclosed the growth blocking the back part of the left passage, and limited only by the posterior nares. From explorations with the probe, it

\* Read before the American Laryngological Association at its eighteenth annual congress.

was further apparent that this mass sprang from some part of the lateral wall. As circumstances rendered an early resort to a more extensive operation not practicable, and the patient was eager for relief, it was resolved to remove the growth with the wire *ecraseur* and curette.

A coarse loop was passed over the presenting part, and a section as large as a hickory nut removed; hemorrhage, which was quite profuse, was arrested by plugging with iodoform gauze. At a second sitting, on the following day, a large wire loop was passed quite through the meatus, and, being guided by a finger in the nasopharynx over to the side wall, the bulk of the growth was fairly caught, constricted, and then torn loose from its attachment. The removal of this much larger mass from the meatus was accomplished with some little difficulty with a flat forceps; in fact, it probably could not have been extracted in this way whole if it had not been quite soft and flexible. The site of the attachment was thoroughly curetted, which was the more easily accomplished on account of the dilated condition of the passage. Free hemorrhage was again arrested by plugging with iodoform gauze. Upon inspection, the growth removed appeared as a solitary tumor of limited base, about the size of a hen's egg, being somewhat longer and much flatter, and greatly resembling in color a section of liver—its surface somewhat irregular, and covered apparently by a thin capsule—having had its attachment over about an inch and a half or an inch and three quarters of the outer wall, originating in the lower turbinated body and apparently confined to it. The remaining portion of the growth here exhibited has retained its general appearance fairly well.

**MICROSCOPICAL EXAMINATION.**—The first sections taken from one extremity of the growth showed a framework of myxomatous tissue inclosing numerous large and connecting spaces, which here and there contained blood, but with no true blood-vessel walls; the structure therefore suggested a venous cavernoma; deeper sections, however, soon showed the bulk of the tissue to consist entirely of new growth composed of a very scant reticulum crowded with round and spindle cells. The following report and the slides exhibited are from expert microscopists of the Cincinnati Hospital:

Transverse sections through the thickest part of the tumor showed that the growth was principally composed of spindle cells, arranged partly in bundles and partly irregularly. In some parts of the section the cells were of many shapes, round, spindle, and irregular cells being mixed together. Very little fibrous stroma was present. Along the free margin of the tumor were found the remnants of the mucous membrane, consisting principally of delicate fibrous tissue richly supplied with blood-vessels, and containing in some places extravasated blood; the epithelial cells of the membrane were wanting. The new growths had infiltrated this tissue, and in part reached the surface. Blood-vessels were abundant, and their walls were more or less completely infiltrated with the spindle and round cells. Large irregular spaces were also abundant in some parts of the growth, and seemed to be venous sinuses whose walls had become partly or entirely replaced by the tumor cells. Diagnosis: Spindle-celled sarcoma.

ALLYN C. POOL. CHARLES S. EVANS.

Two days after the operation I returned to Cincinnati, and a few weeks later a communication received from the patient stated that he found himself entirely relieved of his former alarming symptoms. A little over a year from the date of operation, in August, 1895, the

patient was again seen in Coburg, and it was gratifying to find that no sign whatever of a recurrence was to be detected. The nasal cavity was still abnormally large, the lower turbinated body was represented by a ridge but slightly elevated above the side wall of the passage, and lacking the contour of the normal body. A letter finally, dated May 10th, something less than two years after the operation, announces that the patient is enjoying excellent health, and has had no further trouble with his nose.

In presenting the above-cited case, it is not intended to advocate the removal of sarcomatous growths piecemeal with the snare or forceps, however alluring these procedures at times appear, the writer concurring in the views of Plicque\* and many others that operations which do not aim at total removal of growths of this type, including tissue to which they are immediately attached, are to be looked upon as inefficient surgery. It is offered as a further contribution to the accumulating number of cases which must materially modify the almost unqualified hopelessness of the prognosis which we have been taught to accept regarding sarcoma. If the outlook for the disease in the remoter parts is conceded to be of the gravest, in the depths of the nasal passages, so directly continuous with the intricate recesses of the fragile central bones of the skull, it would seem so unrestricted, so recondit, that little or nothing is to be hoped from operative interference. In fact, however, a review of the seventy or more cases recorded will show that, even when of considerable size, these tumors may have involved the tissue so superficially that they may be successfully eradicated, and that in some instances after protracted growth and repeated recurrence they have been arrested by more extensive operations. An effort on the part of the writer to determine with some degree of accuracy the lasting results obtained from these operations has proved quite futile, owing chiefly to the impossibility of obtaining, even by those who have reported them, their subsequent history, and it is only possible therefore to state briefly results as reported.

In summing up the results of forty-two cases of sarcoma of the nasal passages found in the literature up to 1889, Bosworth† concludes that "sarcoma of the nose does not apparently present the same malignant tendencies as it does when found in other locations."

The twenty-one cases below enumerated, taken from literature since Bosworth's tabulation, do not include several to which reference was found, but which could not be obtained in detailed report; nor do they include cases in which the growths did not originate in the nasal passage. Excluding from these twenty-one cases two (IV and V) in which no operation was attempted, and two others (XVII and XXI) in which it was admittedly incomplete, there remain seventeen cases in which an attempt was made to extirpate the growths. Of these, but two (XII and XIX) are recorded to have died from

\* *Ann. des mal. du larynx*, etc., March, 1890.

† *Textbook on Diseases of the Nose and Pharynx*.

recurrence—one of them four months after the operation. In five cases (IX, XIII, XVI, XVII, and XX) no subsequent history is referred to. The remaining ten are reported as follows:

CASE I.—No recurrence after five months.

CASE II.—Probably no recurrence.

CASE III.—Recovery.

CASE VIII.—No recurrence after short time.

CASE X.—No recurrence in four months.

CASE XIV.—Cure, no recurrence.

CASE XV.—No recurrence.

CASE VI.—No recurrence in one year.

CASE VII.—No recurrence in one year.

CASE XI.—No recurrence in eighteen months.

While these apparently gratifying results are clearly too vague to serve as a basis for definite conclusions, and are further found to be somewhat modified by detailed report, yet in the cases thus far recorded rapid recurrence has followed operation in the minority of instances, and prolonged, if not permanent, immunity in a number of those above referred to, as well as in others occurring in the nasopharynx, not only encourages but indicates a prompt radical operation whenever there appears a fair chance of removing the growths completely, and especially in the case of smaller limited tumors which may be thoroughly exposed by preliminary incision.

The diagnosis of malignant tumors of the nasal passages, and also the nice questions as to when operative interference is contraindicated, and when it is no longer justifiable, have been ably discussed in the literature (Plicque, *Ann. des mal. du larynx*, etc., March, 1890). The malignant character of the growth is usually indicated early in its course. Hæmorrhage is a symptom of the first importance, and is frequently the first to indicate disease; in the cases recorded it was rarely wanting, usually being a premonitory symptom, occurring exceptionally only upon light contact with a probe. As the disease advances, obstruction, acute pain, rapid growth, and at times the appearance of the tumor point more positively to its nature, which may be rendered certain in most instances by removing with snare or forceps a section for microscopic examination.

In concluding the above report, it is desired to urge upon those who operate upon these cases the importance in the present state of our knowledge of publishing their subsequent history over a period of several years. Until this practice is adopted, more accurate information upon the important point in question, which should be in our possession, will remain beyond it.

#### TRACHEAL STENOSIS.\*

By SAMUEL JOHNSTON, M. D.,  
BALTIMORE.

OF the many diseases of the respiratory tract which confront us as specialists we meet with none more distressing to the victim or more alarming to the attendant than those where narrowing of the calibre of the trachea is a prominent feature, and we are consulted in few instances where we feel a greater demand for all the resources of our art.

In stenosis of the larynx tracheotomy, intubation, or other treatment may, in some cases, give relief to urgent symptoms; but when the respiratory space is compromised beyond the reach of these aids, the picture is sad indeed.

The affections producing tracheal stenosis may be conveniently divided into those of extrinsic and those of intrinsic origin. Among the former may be mentioned aneurysm of the innominate artery and of the thoracic aorta; bronchocele, whether of the simple, cystic, or fibroid variety; tumors of the thyroid gland, more especially those of a malignant nature; lymphadenoma; and growths in the mediastinum.

Carcinoma of the œsophagus, by pressure upon the trachea, may cause severe dyspœa.

From within, syphilitic ulceration and its secondary consequences are by far the most frequent causes of tracheal narrowing, but tumors sometimes find their abode here.

The trachea may be pushed from its normal anatomical relations or flattened by compression. In one of my cases an aneurysm of the transverse arch of the

\* Read before the American Laryngological Association at its eighteenth annual congress.

aorta, growing backward, compressed the trachea to two thirds its normal size, as shown at the necropsy.

In the *British Medical Journal*, March 7, 1896, the following interesting case is reported by the Ashanti expedition correspondent, and I take the liberty of incorporating it in this paper:

"On the afternoon of the day that King Prempeh was taken prisoner in his own capital, Surgeon-Lieutenant Spencer, A.M.S., performed an operation on a cousin of the king's at the field hospital overlooking the palaver square. This was the removal of a large fibro-cystic bronchocele, about the size of an ostrich's egg, from the front of the trachea. This tumor had been growing for seventeen years, and involved a large part of the thyroid gland. It extended from near the point of the chin down behind the upper end of the sternum. It was firmly adherent to the trachea, and that organ was flattened out like a ribbon. This caused a great deal of dyspnoea, and there was difficulty at first in the administration of the chloroform. The operation, which lasted nearly two hours, was a distinct success, and when I saw the patient the following afternoon he was sitting up eating rice and milk. If the British occupation of Kumassi was distasteful to the royal family of Ashanti, there is one of them at least who ought, and I am sure will, bear a kindly feeling toward Englishmen—Quassie Appon, who was rescued by a young medical officer from a living death."

Tuberculous disease of the bronchial glands, in children more commonly, sometimes gives rise to symptoms of tracheal stenosis; but the lower end of the trachea and the bronchi are usually the site of the constriction.

I have had instances under my care where in one case an aneurysm of the innominate artery, in another an aneurysm of the arch of the aorta, in another malignant disease of the thyroid gland, and in another malignant disease of the œsophagus caused tracheal stenosis. I shall not, however, give these cases in detail, but simply mention that the only relief afforded these patients was in the judicious administration of antispasmodic and anodyne remedies until death closed the scene.

The predominating symptom in stenosis of the trachea is inspiratory dyspnoea, characterized more particularly by its stridulous nature, and the cyanosis and great restlessness with which it is attended.

Gerhardt points out an important distinction between stenosis of the larynx and that of the lower air-passages.

He says: "When the obstruction is laryngeal, the head is thrown backward as far as possible. When it is tracheal, the head is stretched forward, and the chin slightly depressed, so as to relax the trachea"—a distinction to be borne in mind. The diagnosis in these cases is, in the majority of instances, a matter of difficulty, and our professional acumen must be called into action, together with the use of the great aids to diagnosis to be found in the laryngoscope, physical examination, and, I may add, the œsophageal bougie.

A careful laryngoscopic examination will reveal any

disease of the upper respiratory tract, such as cicatricial contractions, tumors, ankylosis of the crico-arytænoid articulation, various paralyses, gummatous infiltration, œdema, etc.; and a thorough physical investigation will enable the educated ear to detect any abnormal condition of the thoracic contents.

The patient consults us usually with a history of failing health of many months' duration—cough, dyspnoea, and pain radiating from an ill-defined centre being the chief symptoms.

The voice is more or less husky or aphonic, depending upon the degree to which the larynx or the nervous supply to the vocal cords is involved.

Nocturnal attacks of stridulous breathing, with a feeling of impending death, are not unusual; cough is dry and irritative, and the expectoration is sometimes blood-stained. With tracheal pressure are often found evidences of involvement of the neighboring vessels, nerves, lymphatics, and thoracic duct.

A picture bearing upon my title is so graphically given by Sir Thomas Watson that I can not resist quoting his own words. He says:

"We hear the patients complain of the want of breath; and we see how they labor to satisfy this want, when it becomes urgent, by the elevated shoulders, the dilating nostrils, the energetic action of all the muscles that are auxiliary to the respiration; we perceive by the dusky and loaded countenance, the livid lips and ears and eyelids that the blood is but imperfectly arterialized.

"The diminished capability of such blood to support the functions of the brain is made evident by the vertiginous sensations and the delirious thoughts of the gasping sufferers."

The treatment must be in direct keeping with the primary cause of the stenosis.

Surgical aid should always be sought, and when an operation is feasible it should be at once performed. If this chance of relief is denied us, our efforts should be addressed to the symptoms as they arise. Rest, functional and physical, is of primary importance, together with proper nourishment and the inhalation of medicated vapors.

The administration of arsenic, iodide of potassium, morphine, ether and ammonia, and thyroid extract in suitable cases, with the inhalation of chloroform, amyl nitrite, and oxygen in emergencies, will be our best therapeutics.

In this brief but imperfect sketch of the history of tracheal stenosis I have only endeavored to describe a distressing affection, trusting that you may be able from your experience to add some suggestions which may redound to the benefit of this class of unfortunates.

The Colorado State Medical Society held its annual meeting in Denver on Tuesday, Wednesday, and Thursday, June 16th, 17th, and 18th. An excellent programme was gone through with before a large attendance. Dr. Robert Levy was unanimously elected president, and Dr. H. B. Whitney secretary.

## INTERMITTENT DYSPHONIA SPASTICA.\*

By FREDERICK I. KNIGHT, M.D.,  
BOSTON.

SINCE my last communication to this association on dysphonia spastica (in 1889) very few cases have been published, and, judging from my own observation, I must still continue to think it a rare affection. It is possible that there may be a suggestion of it sometimes in the vocal disability of acute inflammation of the larynx, but the well-marked, easily recognized chronic affection of this kind occurs very infrequently.

In the usual manifestation of this affection, when the patient attempts to speak there is such a spasmodic closure of the glottis that it is only by great effort of the expiratory muscles that enough air is forced through the glottis to produce any vibration of the vocal cords, and then only of their edges, causing a high-pitched, jerky voice. There is often a tendency to obtain relief by speaking on inspiration. It has been said that the expiratory muscles may be concerned in the spasm, but it seems more proper to consider the contraction of the expiratory muscles as wholly voluntary, trying to force air through the tightly closed glottis.

In my experience it has occurred much more frequently in men who have overtaxed their vocal organs in public speaking, or talking in a noise or to deaf relatives. No new light, to my knowledge, has been thrown on the pathology or mechanism of this condition. While most cases could be considered cases of neuroses of occupation, like writer's or fiddler's cramp, others probably would not occur except for some lesion which acts by reflex on the phonatory muscles.

I have never yet seen a complete cure. The patient whom I exhibited to the association in 1882 wrote to me recently that his voice was better, implying that it was not well. I have recently seen one of the patients I mentioned in my paper in 1889, and there was no evidence of improvement.

Nothing new seems to have been established in the way of treatment except that more attention has been properly paid to vocal exercises, and the importance of not speaking on inspiration insisted on.

A case which I have had recently has interested me on account of the intermittent character of the affection. I have never had a patient with this affection before who did not during his visit unmistakably betray the nature of his trouble. This patient was a clergyman, who would preach half his sermon in a perfectly natural voice, and then suddenly, apparently when he was fatigued, lapse into the well-known, high-pitched, jerky voice, which continued until he brought his sermon to a close. As another illustration of the way in which rare cases come in pairs I may say that I have just heard of another patient who is intending to consult me, who is said to

have this affection in an intermittent form. The one whom I have recently seen is fifty-two years of age, of gouty diathesis, and has had rheumatic fevers. He has not been subject to bronchitis or hoarseness. The affection of the voice began about a year before I saw him, and he thinks it varies with the condition of the digestion. There was nothing decidedly morbid in the appearance of the upper air-passages, except that the mucous membrane of the right vocal cord was a little rough and thick. Whether this condition of the cord may have acted in a reflex way whenever the patient had fatigued the larynx it is impossible to say, but it may have been that the phenomenon depended primarily on the condition of the larynx produced by strain or improper use (allied to writer's cramp), and, secondarily, to have been excited or developed by the local condition of the right cord, sometimes intensified by hyperæmia due to indigestion.

## A PORRO OPERATION UNDER DIFFICULTIES.\*

By A. H. BUCKMASTER, M.D.,  
PROFESSOR OF GYNECOLOGY AND OBSTETRICS IN THE UNIVERSITY OF VIRGINIA.

THE brilliant results obtained by the modified Cæsarean section have, to a certain extent, lessened interest in the Porro operation, but the Porro, or some of its substitutes, has a clearly defined field of usefulness. It should be done in all cases where the abdomen is opened and the uterus found in a septic condition. This will be admitted, I think, by all obstetricians, but the recognition of the *status septicus* is not always an easy task. In fact, this difficulty of diagnosis has been the cause of many deaths after Cæsarean section which, I am firmly convinced, would not have occurred if the radical plan had been practised, and I think the time has arrived when we should remove the uterus in all cases where we are in doubt. In many cases the operation is an easy one, not demanding operative skill of a high degree, but merely requiring such a knowledge of the principles of pelvic surgery as is taught in our best medical colleges. With a better understanding of the methods of dealing with the stump which we possess to-day, we may say that there is no advantage for the Cæsarean operation over that of Porro on the score of time saved.

The case I have to report presents several points that put it outside of the general run of these cases. It was not one that caused any perplexity as to the proper method of procedure, for the indication was clear. There was a fibro-myoma connected with the uterus so low down that it absolutely prevented the passage of the head. The difficulties of the case, which happily resulted favorably, were due to adhesions, to the exhausted condition of the patient from long-continued expulsive efforts of the uterus, and to the fact that the operation was done in the woods and without conveniences of any

\* Read before the American Laryngological Association at its eighteenth annual congress.

\* Read before the American Gynecological Society, May 28, 1896.

kind. The result shows that we may hope for a good result under very unfavorable conditions.

On the evening of the 24th of April, I was requested by Mr. Finch to see a pregnant woman living some distance in the country. He had seen the patient for the first time a few hours before and found that she had been in labor four days, and that there was some obstruction to delivery the nature of which he was unable to determine. We rode that night about six miles in the woods to a rude log cabin where we found a white woman in labor. The abdomen was enormously distended and she was in an exhausted condition. She had a high temperature and a pulse of about 140. The waters had ruptured four days before, and since then she had suffered from strong expulsive pains. This was her first labor, and according to her reckoning she had gone over her time. The wall of the belly was discolored and bruised, and a satisfactory examination by the vagina or abdomen could not be made, on account of great tenderness. The patient was therefore placed under the influence of chloroform. The extreme poverty of the family was shown by the fact that there was but one basin in the house and no pitcher; but, in spite of this, we were able by a little patience to make the examination without violating the principles of asepsis. When the patient was fully under the influence of chloroform, the most careful abdominal examination failed to discover a living child, for we could obtain neither fetal movements, intermittent contractions, nor the sounds of the fetal heart. The vaginal examination was more valuable in solving the difficulties of the diagnosis. Above the symphysis, at the entrance to the pelvis, could be felt the uterine cervix. The posterior portion of the left oblique diameter was filled by a mass which at first felt like a head that had undergone a long process of molding, but was found to be a tumor of some sort. The anterior part of the left oblique diameter was found to contain a head, or, to state the matter more accurately, the conical projection of a small part of a head. The pyramidal mass composed of the head and the pyramidal mass composed of the tumor were both firmly engaged in the pelvis, and no amount of justifiable force was sufficient to dislodge them.

The condition with which we had to deal was the simultaneous engagement and impaction of a portion of the child's head and a portion of the tumor. The child evidently was dead, because careful and repeated examinations failed to reveal the heart sounds. As in all other cases of impaction with death of the child, three plans of treatment were open: first, we might reduce the size of the child's head; second, we might increase the size of the pelvis; and third, we might avoid the pelvic canal by taking a short cut through the abdominal wall. In making a choice of these methods the shape of the tumor suggested that it had undergone energetic compression by the uterus. The appearance of the woman indicated great muscular strength and she stated that the uterus had been contracting so vigorously that she had been unable to obtain more than short snatches of sleep. This made us apprehensive that the compression had been sufficient to cause death of the tumor, and that symphysiotomy or craniotomy might leave behind a sloughing mass of tissue. The appearance of the patient strengthened the apprehension of septic infection, for she was jaundiced and complained of having suffered from chills and profuse sweats. Of course, these symptoms might have been caused by breaking down of the

fetus inside of the uterus, but the absence of an offensive discharge or of disagreeable odor when the sound was passed made this unlikely. It was then after midnight and we returned home and arranged to operate at once, stopping uterine effort in the meanwhile by morphine.

The efforts of the surgeon to banish dirt and its evil associates from wounded surfaces has led to costly operating rooms and expensive and complicated operating-room paraphernalia. No end of time and hard work has been spent to learn the best method of securing asepsis for the operating surgeon, surrounded by all that wealth can procure to help him, but the conditions under which gentlemen operate in the farmhouse and tenement house have not received so much consideration as they deserve. Much of the operating work in the future, when the general practitioner is prepared to do such work, will have to be done under such conditions. Simple methods of disinfection are fairly well understood and can be carried out under very unfavorable circumstances, but the most annoying circumstance is the absence of material or instruments which may be needed in an emergency. The transportation of materials by satchels, valises, and bags is annoying and apt to cause delay. To rid myself of these annoyances, some years ago I had a trunk divided into compartments so that it would carry not only those used for the operation but an additional supply. It contains two large Arnold's sterilizers, a large receptacle for boiling instruments, and a supply of sterilized towels, sheets, etc., sufficient for several operations, and many instruments. The trunk is sent before with the nurse, and the operator arrives with his assistants, knowing that he will find not only what is necessary for the operation, but all that may be needed in an emergency.

Having made the usual preparations and carried out aseptic rules with the greatest care, I opened the abdomen. A large fibro-myoma presented itself which was found afterward to weigh sixteen pounds and a half. Its surface was covered with adhesions from the omentum and intestines. When the myoma was extracted through the abdominal incision the pregnant uterus was seen connected with the myoma, lying behind it and to the right. When both of these masses had been extracted it was found that a fibro-myomatous tumor of the left ovary, as large as a large orange but much flattened, was also present. In order to free the pelvis the child was extracted through the uterine wall, and so firmly was the head wedged in the pelvis that it required all the force we could exert to pull it out. The placenta was loose in the uterine cavity and the amniotic fluid was full of liquid feces. A piece of wide tape and a Keith pedicle clamp were used to check the hemorrhage temporarily, and the tumors and uterus were removed. The vessels were isolated and ligated and the wound was closed by coaptating its surfaces with a line of deep sutures and then covering everything with peritoneum, so that no raw surfaces were left.

The woman was walking about on the twelfth day, contrary, of course, to my instructions, and she has since made an uninterrupted recovery.

Examination of the specimen showed that gangrene had begun. The fluid in the tissues had a foul smell and had become turbid, and had the uterus not been removed the patient would have died. The notes of this case are presented as a plea for removal of the uterus in cases of suspected poisoning of the uterus.

## A SIMPLE REMEDY FOR ENURESIS.

By JAMES F. PRENDERGAST, M. D.,

PHILADELPHIA.

ENURESIS, we might say, has been playing football with the medical fraternity for generations. It has also upset many a well-matured scheme of remedies for its cure. Many anxious mothers have lain awake nights devising ways and means for saving their bedding from a drenching. Many an unfortunate child has been threatened, coaxed, cajoled, flattered, bribed, reasoned with, and spanked until its fundament was as red as a coal of fire and almost as hot, but all to no purpose; it would still wet the bed.

In looking over the literature of enuresis, one is struck with the great similarity of ideas in causation and treatment, and in the number and variety of the drugs recommended for the cure of the condition, much to the confusion of the young practitioner, as those who have had any experience know perfectly well that nine out of every ten of the drugs so recommended are perfectly worthless. I might ask, at this point, Why is it that men of standing will go on advocating the use of drugs for this trouble which they must know are worthless? And, in fact, for every other disease a like condition exists. It looks very much like a total lack of originality or a patient investigation of facts, or possibly a slight lack of candor for the sake of a little notoriety or advertising. However, that is another story and will keep.

When I was appointed visiting physician to St. John's Orphan Asylum, one of the problems which presented itself to me was the treatment of enuresis nocturna. I did not feel like starting out and trying almost every drug in the pharmacopœia, knowing full well that failure surely stared me in the face. I did a heap of thinking and some reading, with but little satisfaction.

In talking over the subject with the sister in charge—an extremely bright woman and a close observer—I suggested dieting the refractory ones, and ordered one or two simple remedies. Shortly after this, the sister informed me that she thought cold bathing had benefited some of the boys. Here was a suggestion. Why not systematically carry it out? I immediately instructed the sisters in charge of the boys to give every "bed wetter" a cold shower bath or a cold douche every night before putting him to bed. Some of the sisters very naturally felt timid about doing it, saying it would kill the children, give them pneumonia, colds, etc.; but I assured them to the contrary, and that I would be responsible for any injury it would cause the children.

The cold douching was at once put into practice, and has been carried out faithfully ever since, now eight months. Now as to the results, to my mind they have been remarkable. During the past winter eighty boys have been treated with the cold douche, and of this lot only five were being bathed regularly by the latter part of March, and these were only occasionally wetting the bed. From eighty to ninety per cent. of the cases have been completely cured up to the present time, and the other patients have been greatly benefited—that is, they only occasionally forget themselves—not a boy in the whole lot but was improved by the bathing. Two lads—bright, healthy looking, and of nervous temperament—took three months of persistent douching before any impression was made on their spinal centres; but they are now almost cured of the habit—that is, they relapse occasionally, particularly in a change of weather. The phlegmatic type and the pale, anæmic, "lack-of-tone" type were also rather hard to make an impression upon, but all responded in time to the douching.

During the whole course of treatment not a boy was placed on special diet; they ate whatever was served at meals, drank tea at supper, and had as much water as they wished. Not a drug of any kind was given and not the slightest attention was paid to any peripheral causes, such as a long foreskin, tight prepuce, condition of the urine, etc., so that the test was a thorough one. One of the boys had been circumcised a year previous to the cold-water treatment without benefit, but was cured in two weeks by the douching. One very nervous lad was completely cured with one bath, probably owing to the shock and the profound mental impression. One of the cases cured was that of a feeble-minded boy eleven years of age; he is mentally so deficient that it has been impossible to teach him the alphabet after four years' attendance at school, so that mental impression does not wholly account for the cure.

The method employed in treating the cases was as follows: The boy was stripped and placed standing in an empty bath tub; a basin, or a vessel with a spout to it, like a watering can, was filled with cold water and poured over the shoulders and down the back of the subject. In the nervous, delicate children, one dash of water was sufficient for an application; in the sluggish, phlegmatic lads, the dose might be repeated. The boy was immediately rubbed down, dressed in his night clothes, and put to bed. From a hygienic point of view the cold water has proved an excellent tonic; not one of the eighty boys has had a "cold" the past winter. A number of the boys treated suffered from incontinence of urine during the day, but all have been cured. Occasionally we have a backslider whose spinal centre takes a "nap," but it is at once put on guard by a douche or two. The ages of the boys ranged from six to twelve years, and we have four hundred and eighty-five in the institution. Since starting this article, I have learned an important point in carrying out this treatment: it is, that sponging the

back with cold water does not have the same effect as the douching. A private patient brought her boy to me for treatment for this condition. I ordered the cold douching, but the mother, from false motives of sympathy for the child, objected, and compromised by sponging the spine with cold water. She informed me two weeks afterward that cold sponging had had no effect, but that six cold douchings with a fountain syringe had cured the boy; this was a month ago, and the child has not relapsed yet. From this I would judge that the shock of the cold water is one of the important elements in the cure of the condition.

These are the facts; now as to the theory of how our cold douching does good. The centre which controls micturition is situated in the lumbar cord, and by stimulating this centre with our cold douching, followed by a brisk rubbing, we not only act directly on our nerve centre controlling the bladder and sphincter, but by stimulating the circulation we add "tone" to the whole nervous and muscular systems, and the shock producing a profound mental impression, in this way we reach the higher centres in the brain, and what has heretofore been an automatic or involuntary act becomes an act of volition or a voluntary one; in other words, it is subject to the control of the will.

Another thought suggests itself here, and that is, a great many children in our institutions, and a fair proportion out of them, from lack of proper training, have not been taught to exercise control over what was in infancy an automatic or reflex act, and the bed-wetting habit becomes firmly established, hence we must stimulate the nervous and muscular systems in order that they may properly exercise their functions. It is a well-established physiological law that the development of any centre or organ depends upon its receiving its due share of exercise, and that it receive its normal amount of stimulus to act properly. In our enuresis cases—at least a large majority of them—the cold douching furnishes the necessary stimulus, and our inhibitory centre very quickly learns to perform its work normally and exercise control over the bladder.

There is during childhood a lack of development of the centres of inhibitory reflex acts, and in this way the muscular fibres of the bladder, having no inhibitory restraint, are excited to action by even a small quantity of urine in the organ. For this reason enuresis is a normal condition in infancy, and ceases when the child's inhibitory mechanism is more developed. The inhibitory influence of the will is in abeyance during deep sleep, hence nocturnal enuresis is more frequent than diurnal.

Reflex enuresis may be caused by irritation in any portion of the genito-urinary tract, such as calculus, cystitis, vulvitis, phimosis, masturbation, acid urine, overdistention of the bladder, etc. In a large number of enuresis cases the children are of a highly nervous temperament, but the contrary holds true. It will be found that downright laziness and indifference is the

cause in a proportion of the cases. Cold douching is the remedy *par excellence* for this class.

"Rachford states that this condition may depend upon (1) irritable and unstable nerve centres, (2) anæmia with malnutrition, and (3) reflex stimulation of certain nerve centres in the lumbar cord." The causes which produce enuresis may act in two ways, either directly on the centres in the lumbar cord, making them more irritable or unstable, and in that way increasing their reflex excitability, or indirectly through exaggerated reflex causes that affect both accelerator and inhibitory influences sent to the bladder. These influences may originate in the brain or may be the result of external irritation in or near the bladder itself. In any diseases which are accompanied by anæmia and malnutrition the reflex irritability of the lumbar nerve centres is much increased, and enuresis may result.

Von Zeissl shows how reflex causes may start or check the flow of urine. Thus a reflex carried to the proper centre in the cord would, through the motor fibres of the erector nerve, contract the muscular coat of the bladder, and through the inhibitory fibres of the same nerve relax the sphincter vesicæ.

SUMMARY.—We find, in looking over the different theories as to the cause of enuresis, that the great majority of the cases are due to lack of "tone" of either the muscular or nervous systems, and the treatment indicated is to "tone up" the parts at fault and increase nutrition. This we do by our cold douche to the spine, followed by a brisk rubbing, and by giving tonics; the best combination being strychnine, iron, and quinine in doses suited to the patient's age. Diet is also an important point in the treatment of private patients, though we did not diet our patients at St. John's Orphan Asylum; allow only light suppers; tea and coffee should be forbidden. There is another class of cases in which some trouble will be found to exist along the genito-urinary tract. The indications here are to remove the cause and stimulate the nerve centres to exercise proper control over the bladder. I do not expect that we shall meet with the same success in private practice as I have had at the asylum, as mothers, from false ideas of sympathy, will not follow out instructions and do the douching properly. But for our institutions the remedy, I feel certain, will give far better results than any other that has been suggested. I do not wish to appear extravagant in my allegations for the treatment which I here suggest. I am simply giving my results, and have the name and age of every boy treated. I shall continue the douching and report the results after another winter season, as the results reported were obtained from November to April. Since beginning this article, I have heard of a case of enuresis in a young lady that was cured by placing an ice-bag to her spine over the lumbar region. I would suggest that this be tried by some physicians in our large institutions, and also that they try electricity, as slight electric shocks may have the same effect as the cold douchings.

THE  
NEW YORK MEDICAL JOURNAL,  
*A Weekly Review of Medicine.*

Published by  
D. APPLETON & CO.

Edited by  
FRANK P. FOSTER, M. D.

NEW YORK, SATURDAY, JULY 11, 1896.

COCAINE POISONING.

THE *Therapeutische Wochenschrift* for June 21st remarks upon the extraordinary variability of the symptoms in cases of cocaine poisoning. There may be intellectual torpor, tonic or clonic convulsions, or maniacal exaltation. Respiratory disturbances are particularly intense; the breathing is shallow, in severe cases it may be of the Cheyne-Stokes type, and death may occur from respiratory paralysis. Phenomena pertaining to the circulation are less pronounced. Poisoning has been known to follow the use of so small an amount of cocaine as seventy-seven one-thousandths of a grain, and in many cases that have been reported there has been no reason to suppose that the preparation was impure or that the recognized maximum dose was exceeded; idiosyncrasy must, therefore, be assumed to have taken a part in giving rise to the results.

Our contemporary makes the foregoing remarks as a prelude to condensed accounts which it proceeds to give of four cases of cocaine poisoning. The first and second cases were reported by Dr. M. Weinrich in the *Berliner klinische Wochenschrift*. In one of them the patient, who had a tumor of the bladder, had been examined with the cystoscope several times and operated upon with the aid of that instrument and the use of a one-to-fifteen solution of cocaine. On the third day after the operation the same solution was injected, and immediately signs of poisoning showed themselves—unconsciousness, epileptoid convulsions, Cheyne-Stokes respiration, and slowing of the pulse, which was imperceptible in the wrist and hardly to be felt in the thigh. The patient was saved by means of prolonged and energetic artificial respiration. A week later there was occasion to use an injection of half the strength of the preceding ones, and no signs of poisoning showed themselves. Dr. Weinrich's other patient was a man eighty years old. Similar phenomena of poisoning were observed after a urethral injection of a two-to-thirty solution of cocaine.

The first case is remarkable, says the *Wochenschrift*, from the fact that the cocaine had been used six times

without any ill effect, and then on the seventh occasion, without there being any condition especially favorable to absorption, severe poisoning resulted. It seems that the mucous membrane of the urethra absorbs drugs more readily than that of the bladder, the writer goes on to say, but it may be assumed that the vesical mucosa absorbs them more readily when it is diseased than when it is healthy, on account of losses of epithelium, etc.

The third case was reported by Dr. E. Pfister, of Cairo, in the *Berliner klinische Wochenschrift*, 1896, No. 14. The man had suffered with retention of urine a number of times in consequence of vesical calculi. He received an injection of a twenty-per-cent. solution of cocaine into the bladder, and died almost immediately. A Pravaz's syringe, the writer remarks, will hold four times the amount of such a solution as would contain the maximum dose of cocaine, and it is probable that in this case a still larger syringe was used, for only thus can the lightninglike rapidity with which the drug acted be explained. Nevertheless, our contemporary makes the suggestion, somewhat imaginative, we think, that in consequence of prolonged retention of urine *the urethra had become dry*, and therefore absorbed the cocaine with special rapidity!

The fourth case was observed by Dr. G. Duchesne, of Orbec, and reported in the *Année médicale de Caen* for 1896. A man thirty-eight years old had two injections of cocaine into the gum, in order to have a tooth extracted without pain. On the following day he had oedema of the lids of each eye, especially of the upper lid, which increased for forty-eight hours and then subsided entirely. Repeated examinations of his urine showed no trace of albumin. In this case, our contemporary thinks, there was probably a vasomotor paralysis in consequence of the action of the drug on the terminations of the inferior dental nerve, which is a branch of the inferior maxillary, or of a part of the trigeminal, which by its ophthalmic branch of Willis is in close connection with the skin and the mucous membrane of the lids.

Great caution must be observed in the use of cocaine within the urinary passages, says the writer, but the capricious action of the drug is as difficult to guard against as that of chloroform. The use of cocaine is contraindicated in anæmic persons and in those that are the subjects of respiratory or circulatory disease. When cocaine poisoning occurs, amyl nitrite and chloroform should be used, also opium and chloral hydrate for the

convulsions, but above all artificial respiration and injections of camphor dissolved in ether.

#### TRIONAL AS A HYPNOTIC.

THE use of trional as an inducer of sleep is now no novelty, and probably there are few of our readers who have not resorted to it on many occasions with satisfaction. Nevertheless, it is well to note what so capable an observer as Dr. Richard Drews, of Hamburg, has to say about it. In an article which appeared in the *Wiener medicinische Presse* for April 1 and 8, 1896, and is summarized in the *Wiener klinische Rundschau* for June 21st, Dr. Drews remarks upon the frequency with which the physician finds it his chief task to secure for the patient a few hours of quiet sleep, so that he may not only be freed from distress for the time being, but supplied with fresh endurance to battle with the disease. For this purpose a hypnotic is required that is easily taken, that promptly induces restful, dreamless, normal sleep from which the patient awakes refreshed and strengthened, that is harmless and as free as possible from unpleasant collateral and remote effects, that does not beget a habit, and that can be taken for a long time.

Judging of trional by its action in thirty cases, Dr. Drews thinks it such an ideal hypnotic. Nineteen of the patients were adults, and eleven were children. The causes of sleeplessness in the adults were neurasthenia once, hysteria twice, a phlegmon of the hand once, articular rheumatism twice, muscular rheumatism once, sciatica three times, prurigo once, trigeminal neuralgia once, a scald of the foot once, intercostal neuralgia twice, cancer of the uterus once, and pulmonary and laryngeal tuberculosis with severe paroxysms of coughing and profuse sweating at night three times. In the children they were otitis media three times, meningitis with convulsions once, chorea once, night terrors twice, epilepsy once, intestinal catarrh with convulsions once, pneumonia with severe agitation once, and furuncle of the ear once. For the adults, the dose ranged from fifteen to twenty-two grains; for the children, from three to twelve grains, according to the age. It was administered in strict accordance with Goldmann's directions. The adults took it in bed in a cup of hot milk, and then drank another cup of milk; the children took it in their evening broth or in a cup of hot tea. In cases accompanied by severe pain twenty-two grains were always given to the adults instead of fifteen grains.

In twenty-eight of the cases the result was invariably a restful, calm, natural sleep coming on in the course of fifteen or twenty minutes, and on the following morning the patients felt refreshed and as well as the nature of the disease admitted of. In two of the cases, that of phlegmon of the hand and that of cancer of the uterus, the hypnotic action was delayed for an hour or an hour and a half, and did not last for from six to eight hours, as in the others, but only for three or four hours. Both these patients were sleepy the next morning and complained of oppression in the head, of headache, and of weakness, and the one with uterine cancer suffered also with ringing in the ears and with nausea. These phenomena occurred for several days, after each administration of trional, but strict questioning brought out the fact that it had not been taken in the precise manner prescribed.

#### MINOR PARAGRAPHS.

##### A MUNICIPAL EXPERIMENT IN THERAPEUTICS.

ONE of the New York city departments has been dabbling in therapeutics for some weeks past. A ward in Bellevue Hospital has been set apart by the Department of Public Charities for the treatment of dipsomaniacs by a physician who professes to cure the drinking habit. He is not a member of the medical board of the hospital; moreover, the members of the house staff are not allowed to appear in the ward, so we are informed, and there is no provision for the treatment being supervised or even observed by any medical officer of the hospital. The whole affair seems to be an experiment on the part of the department. The medical profession, and especially the medical board of Bellevue Hospital, ought to protest against such a perversion of the powers of a municipal department. It is intolerable. We say this without any prejudice or animus against the physician who has thus been dignified, but on general principles.

##### THE JOURNAL'S NEW DRESS.

WITH last week's issue, the first number of volume lxiv, the *Journal* appeared in a new typographical dress. The print, it will be seen, is somewhat larger than before and more easily read by him who runs. There are many physicians who do a great part of their reading while they are on their daily round, and it is more convenient for them to take along a journal than a book. They will appreciate the change. A further advantage is that each issue is to be printed from new type—type actually made in the process of composition—so that the print is expected to be as clear months or years from now as it is in this number. This, however, applies only to the text, not to headings, foot-notes, and tabular matter.

##### ITEMS.

**Infectious Diseases in New York.**—We are indebted to the Sanitary Bureau of the Health Department for

the following statement of cases and deaths reported during the two weeks ending July 7, 1896:

DISEASES.	Week ending June 30.		Week ending July 7.	
	Cases.	Deaths.	Cases.	Deaths.
Typhoid fever.....	13	2	15	3
Scarlet fever.....	64	6	70	7
Cerebro-spinal meningitis....	1	2	2	3
Measles.....	172	13	149	7
Diphtheria.....	232	33	237	37
Tuberculosis.....	177	119	115	121

**The Pronunciation of Greek.**—Dr. Achilles Rose has furnished us with the following translation from the *Acropolis* for May 11th (24th): "The minister for public instruction, on the occasion of the measures taken recently in France for the abolition of the Erasmian pronunciation and the introduction of living Greek pronunciation for the teaching of ancient Greek, and in consequence of representations of our ambassador in Berlin, Mr. Cleon Rangabis, appointed a committee consisting of Mr. G. Mistrioty, Mr. Th. Papadimitracopoulos, Mr. G. T. Typaldos Kosakis, Mr. G. Kalostypus, Mr. G. Kambouruklos, Mr. G. Hatzidakis, Mr. G. Kofinotis, and Mr. Sypridis Sakelaropoulos, who, under the presidency of the minister of public instruction, will proceed to prepare a memorandum containing, first, the reasons in support of the correctness of the modern Greek pronunciation; second, the advantages which foreign students will have in understanding modern Greek; and, third, directions to the representatives of Greece abroad in regard to their action in the matter."

Dr. Rose has also sent us the following translation from the *Acropolis* for May 12th (25th): "The news which was published by us yesterday concerning the appointment of a great committee whose aim is to be to prepare a scientific work by which the Erasmian pronunciation, which is taught in several parts of the civilized world, will be abandoned for the real one through which we now understand each other in Greece, is very important in every respect. The committee which has just been established has the following history: The ambassador of Greece, in Berlin, Mr. Cleon Rangabis, some years ago, when he served as *chargé d'affaires* of Greece at the Court of St. Petersburg, approached the Russian government concerning the change of the system of teaching the Greek language. He was sufficiently successful in this, because he found the Russian government to be well disposed to it. Now he has made the same efforts in Germany and, after the raising of this question about the abandonment of the Erasmian pronunciation in France, he writes to the minister of public instruction, asking to be assisted in this important matter concerning our language. Immediately the minister of public instruction, recognizing the importance of the proposition of Mr. Rangabis, appoints a committee, which will busy itself in the preparation of a long statement in which there will be given the reasons why the real pronunciation of the Greek language is the same which the modern Greeks employ. Thus the question has two aspects: 1. The preparation of a scientific work, that is, a statement showing that the Erasmian pronunciation is not the pronunciation of the ancients. 2. Diplomatic action in order that the government, too, may accept our propositions. The minister of public instruction considers the question a most important one, since many things depend on its favorable solution. He exchanged views with the Prime Minister, who accepted

his opinion and promised to help him in the matter. Mr. Hatzidakis, professor of comparative philology in the University of Athens, the celebrated linguist, will prepare the work."

**The Albany Medical College**, which is the medical school of Union University, will enter upon its next session, beginning on the 29th of September, with its resources very materially enhanced by the Bender Hygienic Laboratory, a handsome and substantial building which is expected to be ready in the autumn. It has been generously given to the college by Mr. Matthew W. Bender, of Albany. It will be equipped with the necessary appliances for the practical study of histology, pathological anatomy, and bacteriology. It is announced that the laboratory will be under the charge of Dr. George Blumer, formerly an assistant in pathology and bacteriology in the Johns Hopkins University. We congratulate the college on this fresh evidence of its prosperity and enterprise.

**The International Congress of Dermatology.**—The following announcement has been issued by the secretary, Dr. George T. Jackson: There will be a museum containing drawings, casts, models, naked-eye preparations, microscopic specimens, and work and atlases pertaining to diseases of the skin. An exhibition of patients, and demonstrations of the same, will also be given. All those who desire to contribute to this department will please address Dr. James Galloway, 21 Queen Anne Street, Cavendish Square, W., London. There will be an exhibition of cultures and microscopical preparations of organisms connected with the skin and its diseases. Any communications in regard to this department should be addressed to H. G. Plummer, Esq., Wunderbau, Sydenham, London. Information in regard to hotels will be furnished on application to George Pernet, Esq., 77 Upper Gloucester Place, London, N. W.

**The French Surgical Association.**—The tenth meeting of the Association française de chirurgie will be held in Paris from the 19th to the 24th of October, under the presidency of Professor Terrier. The inaugural session will begin on Monday, October 19th, at two o'clock. Subjects for discussion are announced as follows: The Surgical Treatment of Clubfoot (Dr. Forgeue, of Montpellier, reporter); The Treatment of Genital Prolapses (Dr. Bouilly, of Paris, reporter). Members are requested to send, by the 15th of August at the latest, the titles and conclusions of their papers to the secretary general, M. le Dr. Lucien Picqué, rue de l'Isly, Paris, who may be addressed for any information concerning the congress.

**An Ether Prize Fund for the Boston City Hospital.**—The Trustees of the Boston City Hospital have received a gift of \$1,000 from Mr. Townsend W. Thorndike under the following conditions: "I wish to give \$1,000 to the Boston City Hospital to found the 'Herbert L. Burrell ether prize fund,' from the interest of which a prize of \$20 shall be given semiannually to the surgical house officer who administers ether in the most skillful and humane manner. Only surgical house officers of the Boston City Hospital shall be eligible in competition for it, the award to be made by three judges to be appointed by the superintendent of the hospital and senior surgeon. In case no officer is considered worthy of the prize, the interest shall be added to the principal. Should the principal increase to such an amount as shall be con-

sidered sufficient to warrant the offering of a second prize of lesser amount, such a second prize shall be established, and shall be known as the 'William H. Thorndike ether prize.'"—*Boston Medical and Surgical Journal*.

**Creolin.**—This popular antiseptic agent has been generally accorded entire freedom from toxic effects, but, in the light of some recent experiments upon lower animals, this superiority must be called in question. Professor Hobday, of the Royal Veterinary College, England, reports in the *Lancet* that two ferrets subjected to applications of the drug, diluted with water in the proportion of two ounces to a quart, died in half an hour. Subsequent investigation proved it to be an irritant and narcotic poison to both dogs and cats, especially when applied over a considerable area of the body. Such a report emphatically suggests caution in treating extensive wounds upon the human body with creolin as a dressing.—*Medical News*.

**Change of Address.**—Dr. Bruno Getzlaff, from Wapakoneta, Ohio, to Attapulga, Georgia (temporary).

**Army Intelligence.**—*Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from June 28 to July 3, 1896:*

ALEXANDER, CHARLES T., Colonel and Assistant Surgeon General, is granted leave of absence for two months, to take effect on or about July 8, 1896, or as soon thereafter as practicable.

DAVIS, WILLIAM B., Captain and Assistant Surgeon, will, in addition to his present duties, take charge of the Medical Supply Depot in New York city during the absence on leave of ALEXANDER, CHARLES T., Colonel and Assistant Surgeon General.

**Naval Intelligence.**—*Changes in the Medical Corps of the United States Navy for the Week ending July 4, 1896:*

ARNOLD, W. F., Passed Assistant Surgeon. Detached from special duty in China and Japan and ordered to return home.

BOGERT, E. S., Passed Assistant Surgeon. Ordered to the New York Navy Yard.

CRAIG, T. C., Passed Assistant Surgeon. Detached from the New York Navy Yard and ordered to the marine rendezvous, New York.

HIENBERGER, L. G., Surgeon. Detached from the marine rendezvous, New York, and ordered to the hospital, Widow's Island.

PARRISH, H. F., Assistant Surgeon. Ordered to the Naval Laboratory, New York city.

#### Society Meetings for the Coming Week:

MONDAY, July 13th: Gynecological Society of Boston; Burlington, Vt., Medical and Surgical Club; Norwalk, Conn., Medical Society.

TUESDAY, July 14th: Medical Societies of the Counties of Chautauqua (annual), Clinton (semi-annual—Plattsburgh), Greene (quarterly), Jefferson (semi-annual—Watertown), Madison (annual), Oneida (quarterly—Utica), Ontario (annual—Canandaigua), Rensselaer, Schuyler (semi-annual), Tioga (Owego), and Wayne (annual). N. Y.: Richmond Academy of Medicine and Surgery; Norfolk, Mass., North District Medical Society.

FRIDAY, July 17th: Brooklyn Medical Society.

## Births, Marriages and Deaths.

### Married.

GREENING—SCHEEN.—In Coushatta, Louisiana, on Tuesday, June 30th, Dr. R. C. Greening and Mrs. L. Scheen.

JOHNSON—HOTCH.—In College Park, California, on Wednesday, June 24th, Dr. Joseph Newton Johnson, of San José, California, and Miss Cora May Hotch.

PETERSEN—BECK.—In Jersey City, on Tuesday, June 30th, Dr. John Petersen and Miss Christina Beck.

PFISTER—GOFFE.—In Montclair, New Jersey, on Tuesday, June 30th, Dr. Carl Pfister, of New York, and Miss Helen Goffe.

STILWELL—CLEMENTS.—In Kansas City, Missouri, on Friday, June 26th, Mr. William Elmer Stilwell and Miss Alice M. Clements, daughter of Dr. Joseph Clements.

### Died.

BROWDER.—In Gallion, Alabama, on Sunday, June 28th, Dr. James R. Browder.

WELLES.—In Tarrytown, N. Y., on Wednesday, July 1st, Julia C. Welles, wife of Dr. Frank M. Welles, of New York.

## Letters to the Editor.

### THE EARLY DETECTION OF THE LINE OF DEMARCATION IN CASES OF GANGRENE.

POSERET, CONN., July 6, 1896.

To the Editor of the *New York Medical Journal*:

SR: I am accustomed to make use of a faradaic battery to determine the future line of demarcation on limbs in which large vessels are occluded, which in selected cases has been of so much practical importance and is of such simple application I will describe it. If one pole of a faradaic battery is held firmly in position near the extremity of the limb, and the other pole is passed up directly toward the body, the patient will immediately flinch when the sponge passes the point where the line of demarcation will form. By passing the pole at points a quarter of an inch apart until the whole circumference of the limb is covered, the line can be accurately marked out. In cases where the heart's impulse is so weak that one is in doubt whether or not pulsation can be felt, when the artery runs near the surface, this expedient is especially valuable, as an earlier operation can be decided upon and much of the patient's vitality can be saved which would be lost were we to wait for the line to show on the integument.

As an illustration, I will give a synopsis of the following case:

C. M., a French woman, married, twenty-nine years of age, was admitted into the hospital on October 9, 1895. She had been discharged from a neighboring hospital as incurable; the diagnosis was "caries of the spine." Her family history was negative, and she gave no history of traumatism.

She was emaciated and had hectic, her temperature was 103.5° F., her pulse weak, 98, she had no appetite, she was constipated, her heart was weak, her lungs were normal. Evidently she was syphilitic. The anterior

superior spinous process of the ilium was protruding through the skin and covered only by muscular attachments, and there were sinuses extending from the process through the groin to the symphysis pubis and several also opening on the anterior aspect of the thigh. The diagnosis of caries of the spine was doubted, but I could reach nothing with a probe to settle the question. The sinuses were slit up under ether and the hand was passed over the iliac muscles, which appeared in normal condition. On following the crest of the ilium from behind forward, a necrosed area was found two inches and a half posterior to the spinous process. An incision was made over the crest of the ilium and bone two inches in length and an inch in depth removed. A drainage tube was inserted and the wound healed satisfactorily. The patient gained in flesh and strength and there was no rise of temperature four days after the operation.

On November 1st my service ended. When I took up the service again in March, I found the same patient with a temperature of 103°, the wound in the groin well healed, pain in the leg, and a dark spot over the os calcis, and one over the metatarso-phalangeal joint on the outer side of the foot. I ascertained the line of demarcation with the battery (as described), as her general pulse was so weak that I could not determine whether there was pulsation in the popliteal space or not. The line ran below the tubercle of the tibia anteriorly and two inches above the popliteal space posteriorly. Amputation at the middle third of the thigh was performed, and the patient was discharged, cured, on June 1, 1896.

S. BURDEN OVERLOCK, M. D.

## Proceedings of Societies.

### SOCIETY OF THE ALUMNI OF THE CITY (CHARITY) HOSPITAL.

*Meeting of May 6, 1896.*

The President, DR. R. C. NEWTON, in the Chair.

(Concluded from page 23.)

**O'Dwyer's Tubes.**—DR. PROBEN presented some instruments that Dr. O'Dwyer had been working on since 1869. The primitive experiments had dated from the introduction of a catheter through the nose into the larynx; these, however, could not be retained for any length of time or could not be kept clean. Later, a tube had been constructed on the principle of a bivalve, but here the difficulty of constructing a spring which would exert the proper pressure had been almost an insurmountable one. If the blades were too loose, apnea would occur; if too tight, ulceration would set in, and the open spaces allowed of protrusion of the mucous membrane. O'Dwyer had constructed four different bivalve tubes, each somewhat modified. The fifth instrument had differed from the four preceding, in that it had been a tube, not a bivalve, with an upper part called the head, and an opening posteriorly for dislodging it when *in situ* by an extractor. This latter instrument was shown. The tube was from the first recorded case of recovery from intubation (May, 1884). The uniform calibre of the tube would not have kept it in the larynx had it not been for the posterior buttonhole, which allowed the mucous membrane to protrude and thus firmly hold it. This had been modified so that the buttonhole

had been eliminated and the head somewhat reduced in size, in order to prevent the ulceration of the epiglottis. The tubes had been increased in length, a shoulder substituted for the vocal cords; but the tubes would protrude from the larynx during coughing or swallowing, and had to be pushed in place by the finger. In order to overcome this difficulty, and it was said by O'Dwyer that this was the solution of the most intricate problem, an expansion of the middle of the tube had been necessary. Numerous experiments had had to be made in order to determine the proper relation to the tube proper, and the proper sizes according to age, which had been finally crowned with success. An improper tube produced ulceration at the base of the epiglottis, at the cricoid cartilage, and at the distal extremity of the tube. The latter had been overcome by rounding the lower edge of the tubes. A number of instruments were presented, showing the primitive extractor and introducer, with the most modern instruments. All these improvements had been made by O'Dwyer himself, with not a single suggestion from anybody, and too much credit could not be bestowed upon one whose name was now known throughout the world. A tube with a loose epiglottis was also shown. The speaker spoke of the large cylindrical tubes which served for the exit of dislodged membrane, but said that, owing to their size, they were left in place only a few hours.

Dr. Proben also presented a set of tubes for forced artificial respiration. O'Dwyer's laryngeal tubes were conical, and were the outcome of Fell's method. Wood had found that in dogs, when respiration failed in ether or chloroform narcosis, by introducing a tube into the trachea he could bring back the respiration and cardiac beats. O'Dwyer had worked upon the principle of completely clogging up the larynx by means of a tube, at the same time using pressure and forcing the air into the lungs, and in that way distending them. This was a direct method of artificial respiration, and had come into use in some of our New York hospitals. Its applicability to narcosis from chloroform, opium, etc., showed it to be the most successful method in use. The tube was introduced into the larynx, tightly plugging at the cricoid cartilage, and connected with a pair of bellows, and the air was forced into the lungs at the rate of twelve to twenty times a minute. Care should be taken to prevent the possibility of mucus or blood going into the lungs, and where there was bleeding from the buccal cavity the tight fit of the tube prevented this. The pressure of the bellows should be regulated according to the vital capacity of the chest, and, in order to prevent a drying of the mucous membrane, it was passed through a receptacle containing a sponge wet with water. Probably the future would show that another inlet containing oxygen would be of decided use.

Dr. JOSEPH E. BISSELL spoke of having seen the last instrument work several times. One case he remembered, that of a young girl brought in with morphine narcosis. She had taken twenty grains of morphine, and when the speaker saw her her respiration had about stopped and no pulse-beats could be detected. The apparatus of Dr. O'Dwyer had brought her back; she had recovered consciousness completely, and had been able to talk coherently, but she had died in the next twenty-four hours, of pneumonia. The second case had been about the same, which had also terminated fatally, probably by pneumonia. He remembered Dr. O'Dwyer saying that he hoped to perfect the apparatus so as to prevent the introduction of unfiltered air.

Dr. F. W. MERRIAM asked the previous speaker if, in another case, he would use the apparatus; and whether the pneumonia was not due to cold air introduced into the lungs.

Dr. BISSELL stated that he would do the same thing again. There had been great exposure before the patient had been brought to the hospital, which might have allowed the development of the pneumonia.

Dr. RUPP said that an injustice was done Dr. O'Dwyer when Bouchut was given too much credit for the idea of intubation. Dr. O'Dwyer by persistent study had brought the idea of intubation to that state of perfection which allowed all the credit to be given to him for having made intubation not only practicable but successful.

Dr. PROBEN said that a number of cases of deep opium and chloroform narcosis, where the respiration and cardiac beats had been scarcely perceptible, had been successfully treated. In others, again, the patients had been kept alive for over twenty-four hours. It was surprising how the respiration could be absolutely controlled by the lever of the bellows; this might also be said of the cardiac beats in some cases.

**Sudden Death and the Coroner.**—Dr. JOHN B. HUBER read a paper on this subject (see page 12).

Dr. RUPP stated that much of the practitioner's uncertainty concerning his relations to State and city officials would be done away with if medical colleges would attend to so important and practical a matter, which concerned not only the practitioner's peace of mind, but the honor of our profession in the estimation of the public and officialdom. Concerning Dr. Huber's remarks on the relation of thigh fractures to the death of old people, the speaker mentioned a case that had occurred in his practice, which had shown with what scant respect the practitioner was treated by those "in authority." A death certificate had been made out with the thigh fracture as a remote cause leading to the immediate natural causes of death. The thigh fracture had been sustained months before death occurred, and had been mentioned in the certificate for the benefit of the statistics of the health board. Months after this old woman had been buried, her son had met the speaker on the street, and had said that the certificate had not been accepted, that the health board had given the case to the coroner, who in turn had given his own certificate. The practitioner had been entirely ignored. Instances were constantly taking place which demonstrated clearly enough that the practitioner was not dealt with by health and coroner's officers with that amount of respect and circumspection which were his due. If health and coroner's officers communicated directly with the practitioner, instead of indirectly through his patients, much folly and injustice would be avoided, and the proper and true status of the profession would be maintained in the estimation of the public.

Dr. JOHN L. ANDREWS asked in regard to the relation of the physician to the authorities in cases of abortion, and whether before a case was touched the physician should have another physician see the case, in order to protect himself. He spoke of a case last winter in which two reputable physicians had examined a case of puerperal sepsis due to abortion; they had been arrested, brought to court, and caused considerable trouble, yet they apparently had taken all the steps necessary to protect themselves. On the other hand, if they went still further and reported the case to the coroner before death, or when they took charge of it, and the patient

recovered and the case became public, the physicians were liable to be sued for damages to the patient's reputation. If, however, they did not report it, and the patient died, they were liable to be investigated by the coroner. He asked what course physicians could pursue in order to protect themselves.

Dr. F. W. MERRIAM spoke of two cases of his, occurring in children who had died suddenly; they had had convulsions, and had never come out of them. On the certificates he had given "convulsions" as the cause of death, and they had been sent back, with the report that it would not do. The speaker had reported to the board of health that he did not know what the children died of; the convulsions might be the forerunner of scarlet fever, meningitis, or something else; he could make a guess as well as the coroner. He remembered one case where the coroner had assigned "measles."

Dr. RAMON GUITERAS asked the writer of the paper his opinion as to the best thing to do if a physician was called to see a case in which the patient did not confess abortion, and where, after examining, he thought an abortion had been performed.

Dr. BROOKS H. WELLS said, in regard to reporting cases of abortion, he thought that, unless the physician was certain the patient was going to die, it was not his duty to notify the coroner. The first duty of the physician was to the patient. If a case came to him that was septic, it was his duty to cure. If he suspected criminal interference, he could always do any operation necessary, in the presence of one or two witnesses, which would protect him.

Dr. CARTER S. COLE stated that he had found, on inquiry at the district attorney's office and from consultation with the coroner, that physicians were bound by the law only to report cases in which death had occurred as the result of criminal interference; the law did not compel the physician to report his suspicions unless death ensued. He thought every man would be able to protect himself in cases of suspected abortion by getting a written statement from the patient signed in the presence of witnesses, and in case of death handing it to the coroner in the place of an ante-mortem statement. As to cases of suicide, he believed that the position taken by Dr. Tuttle that a coroner was not compelled to give a report of cases to the public press was the right one, and that the profession owed him a debt of gratitude. If such a report would be of value to the public in general; if it would prevent crime; if it would prevent the commission of suicide to go into the details of a case, it might be proper. In the case he had recently been connected with there had been no reason for making it public. The patient had been insane, and during her insanity had taken up a razor and cut her throat. She had been living in a furnished apartment with no one but her son. She had been raised in luxury: the only thing they had left of their former estate had been their pride; and it was very little to ask that as little publicity be given to it as possible. The speaker had stated the case to Dr. Tuttle, who had agreed with him that there had been no need of its being made public, and it had been through no fault of the coroner's that the facts had become known to the public press, and through it to the people. The fact that it became public had been due, in all probability, to the betrayal of the trust of some one concerned, and the gentleman might have a chance to answer for it yet.

The PRESIDENT said that in the State where he lived (New Jersey) there was a physician who was really the

coroner, and he had always been very considerate of the private affairs of patients, and had kept them as far as possible from publicity.

Dr. HUBER said that in regard to the law, it was somewhat conflicting. The law stated that in cases where crime was suspected, it was the duty of every citizen to notify the authorities. On the other hand, the physician, both by instinct and by the law, was impelled to keep inviolate the secrets of his patients. In regard to cases of abortion, until the physician suspected that the patient would die, he thought it would be well not to mention the subject. As a protection to himself, the physician should operate in the presence of a colleague, and in case of death from criminal abortion or as the result of crime in any other way, the best thing would be to visit one of the coroners, tell him privately the whole matter, as between man and man, and bind him to secrecy. He then protected himself, had done his duty, and did not divulge secrets in a public manner. So far as reporting the commission of crime was concerned, the law was to the effect that it should be reported. But, as a physician said some time ago, he did not intend to make himself a spy for the district attorney's office, and public sentiment would probably uphold any physician who took that view.

**Acute Otitis Media with Reference to some of its Prominent Symptoms.**—Dr. A. T. MUZZY read a paper on this subject (see page 11).

Dr. RUPP said that one mistake made by specialists when describing diseases and symptoms for the benefit of general practitioners was that the pictures presented were too clear and plain, and on those accounts could not be brought into harmony with the ordinary experience of the general practitioner. Symptoms indicating the presence of otitis were often marked in the course of pneumonia in children, and the first sign of this complication was a purulent discharge from the ear. The same might be said of scarlet fever. A child's ear was not always easy to examine, and puncturing the membrana tympani would not always give the relief which was so enthusiastically proclaimed by some teachers. But, for all this, examinations of the ear should not be neglected, and neither should paracentesis tympani be discarded when a bulging drum membrane had been diagnosed. A child might be simply restless, and it might be teething at the time, and the child's parents and nurse might want its gums cut so that all hands could sleep. The speaker had been called to see such a case this day. Although the child was restless night and day, and was teething, it was found that the restlessness was due to a subacute otitis that had nothing to do with dentition. The ear treated, the child rested undisturbed by the teething. It was not denied that the teeth gave rise to ear troubles. Otitis sometimes gave rise to pain in the region of the brow, and, if too much attention was given to such single symptoms, mistakes would be made. A physician had made this mistake in a case afterward treated by the speaker. A word or two might be said in favor of the dry treatment with boric acid, which had been so roundly condemned by some first-rate men. It was not a remedy to be used promiscuously, any more than mercury or iodide of potassium was; but no practitioner should cram the ear full of any powder unless he had diagnosed the conditions which justified its application. Properly used, boric acid powder could do no harm.

Dr. W. L. CARR said that in children often otitis would follow a disease that had depressed the child's vitality,

and it was difficult to separate the symptoms due to local inflammation. He spoke of a case he had seen in consultation, where the child had had pneumonia, and otitis had produced marked cerebral symptoms, irregular pupils, which did not respond to light, irregular pulse, and vomiting. The child had been constipated for some time. The symptoms had disappeared when the drum had been punctured. To say that from symptoms alone a diagnosis could always be made he thought would be an error.

Dr. MERRIAM said that often he was called to see children screeching with earache. One expedient he had employed was to hold the nose closed, have the child open its mouth, and blow violently into the child's mouth; it would often relieve the patient instantly. At another time hot tobacco smoke would give relief. He had used opium and olive oil, and in the last case a solution of cocaine.

Dr. COLE spoke of a simple remedy that had been suggested to him when a boy by a country physician. It was to take a small piece of sponge, tie a thread around it, dip it in very hot water, wring it out, and push it well into the canal, covering it from the air. It would give instant relief. It was applying a hot poultice directly to the eardrum.

Dr. GUITERAS said that in Cuba the great remedy for earache in children was to take one or two cockroaches and squeeze the juice of them into the ear. He asked the writer of the paper how the salt water caused otitis media; whether it was from the impurity of the water itself.

Dr. MUZZY said he thought that where the disease followed bathing it was caused by inhalation of the water more frequently than by a blow of a wave from the outside, because of the well-known impurity of the water at the beaches. Scarcely any water, except perhaps, spring water, would be free enough from germs. It was possible, and sometimes was the case, that if the nasal-pharyngeal mucous membrane was not in sound condition, its secretion might infect the ear, but the physicians he had talked with had thought that the infection came from outside material. The course of the disease in a healthy person with sufficient exciting cause was usually a perfectly clear, straightforward one. As to the dry treatment, he remembered as a student taking a patient of one of the well-known aurists in town to the mountains, with instructions to blow the ear full of boric acid every second day. He thought the dry treatment, used in moderation, first disinfecting and cleansing the ear, and then fluffing the powder in so as to make a coating for the surface, was beneficial. He spoke of a case where the patient had been previously subjected to the excessive dry treatment. His ear had been filled with powder, which, when mixed with the discharge, would crystallize, and on his next visit to the physician he would be subjected to torture while the mass of crystals was torn out. The ear would bleed profusely, and the same amount of powder would again be put in. The association of meningitis with the otitis, where it existed, was very close, and it was often difficult to tell where one disease began and the other left off. In all such cases that he had seen the otitis had come first. In regard to inflation, he advised using a Politzer bag for the purpose, as more direct, and avoiding danger to the surgeon. He thought the most beneficial wet treatment was with hot water or the heat of an onion. It was the heat of the application that was beneficial. In applying the artificial leech, we should ascertain with the finger where

the inflammation affected the interior or posterior part of the ear, and then apply the scarificator and the leech.

### Book Notices.

*Twentieth Century Practice.* An International Encyclopædia of Modern Medical Science. By Leading Authorities of Europe and America. Edited by THOMAS L. STEDMAN, M. D., In Twenty Volumes. Volume IV. Diseases of the Vascular System and Thyroid Gland. Volume V. Diseases of the Skin. Volume VI. Diseases of the Respiratory Organs. New York: William Wood & Co., 1896.

THE greater portion of the fourth volume of this work is devoted to the section on diseases of the heart and pericardium, written by Dr. James T. Whittaker. An historical note, commensurate with the knowledge of this subject in former days, prefaces the consideration of the various diseases of the pericardium. The different cardiopathies are described concisely, yet comprehensively enough to present the latest facts relating to them. The author has endeavored to save space by omitting references, a fact that is likely to be regretted by those who might wish to investigate certain topics at greater length than their consideration in such a work as this would allow of.

Dr. A. E. Sansom is the author of the section on diseases of the blood-vessels. This author considers that malaria may be a cause of aortitis, but it would seem to the writer that the idiosyncrasies of the individual and the effects of residence in a climate where paludism is prevalent are more likely to cause the disease of the artery than the *Hæmatozoon malaria* or the toxins it may elaborate. Certainly the experience of Sir Joseph Fayrer, Laveran, and others who have resided where paludism is rife does not support Dr. Sansom's view. The author accepts the conclusions of Hippolyte Martin that inflammation of the *vasa vasorum* is primarily the cause of local infiltrations and fatty degenerations of the aorta; yet he holds that chronic aortitis may be due to a senile change, or to muscular over-exertion, or to gout, or to excess in alcohol, tobacco, or eating or drinking. On page 473, where the remark might be overlooked, he writes in regard to these supposed ætiological factors: "I believe those changes to be really secondary to lesions of the nutrient arteries of the vessel wall and to the invasion of the deeper layers of the internal coat by the oval and round cells, though this is difficult to demonstrate." While the difficulty of demonstration is undoubtedly real, yet the trend of pathological investigation supports the proposition. In the section on treatment Dr. Sansom cautions the reader about trinitrin, as his experience has shown him that there "is a nitroglycerin mania just as there is a morphomania."

Dr. Sansom concludes that atheroma is the result of an insoluble particulate material that blocks the *vasa vasorum*, and arteriosclerosis is due to a soluble and diffused poison that affects the internal or the external coat of the vessel. The entire chapter forms an excellent survey of the diseases of the arteries and veins.

Dr. Bertrand Dawson is the author of a section on diseases of the lymphatic vessels that satisfactorily presents our most recent knowledge in regard to morbid processes involving that system.

Dr. George R. Murray is the author of the section on diseases of the thyroid gland, including myxœdema, cretinism, exophthalmic goitre, goitre, and acute thyreoiditis. The greater portion of this section is devoted to myxœdema and exophthalmic goitre, and both of these topics are discussed in a very thorough fashion that includes the review of all, or almost all, the literature relating to these diseases. The author recommends the administration of thyroid extract in cretinism, and says the value of the treatment depends upon the use of the remedy in the earliest stage of the disease. The entire section is thorough in its discussion of the various diseases of the thyroid gland.

Volume V is devoted to the consideration of the diseases of the skin. The first section treats of the anatomy of the skin and its appendages, and was written by Dr. Charles W. Allen, who has condensed what there was to be said as much as is compatible with clearness.

Dr. L. Duncan Bulkley is the author of the section on parasitic diseases of the skin, in which he treats of the diseases due to animal or to vegetable parasites and of those due to parasites of uncertain nature.

The section on erythematous and bullous affections is by Dr. Henry H. Whitehouse, who includes in the first-mentioned subject diseases in which hyperæmia is the most important and prominent feature, and in the second pemphigus, hydroa, dermatitis herpetiformis, and pompholyx.

Dr. James Nevins Hyde is the author of the section on eczema and dermatitis. Dr. Hyde directs attention to the fact that the revelations of modern bacteriology have undermined and destroyed the doctrines that were illustrated by such phrases as darte, tetter, rheum, etc., and shown that there is no one cause capable of producing an eczema of variable type, and most eczemas are such. The very thorough *résumé* of the pathology of eczema should give a clear idea of the disease processes and of the means best adapted for their relief.

The section on squamous affections is by Dr. H. Radcliffe Crocker, who writes of psoriasis, pityriasis rubra, and pityriasis rosea in his familiar and thorough style.

Dr. L. Brocq is the author of the section on papular affections, which include the lichens, the prurigos, pityriasis rubra pilaris, and lichen scrofulosorum, the two latter diseases being included because their elementary lesion seems to be a papule. The author has added a new word—lichenification—to the nomenclature of dermatology; it is a morbid condition which may be primary or secondary, and includes the pathological changes characteristic of lichen.

Dr. Henry H. Whitehouse has written the section on pustular affections, a phrase that includes impetigo, impetigo simplex, impetigo contagiosa, impetigo herpetiformis, ecthyma, and syccosis, which are well described.

Dr. H. Radcliffe Crocker is the author of the monograph on phlegmonous and ulcerative affections, under which heading are included furuncles, furunculus orientalis, gangrene of the skin, and phagedæna tropica.

That Dr. Van Harlingen is the author of the sections on diseases of the sebaceous glands and diseases of the sweat glands is sufficient guarantee of the thoroughness with which these subjects have been considered.

Dr. Douglass W. Montgomery has included a great deal of information in a small compass in his monograph on diseases of the hair and nails.

Benign neoplasms are described by Dr. John T. Bowen at considerable length and in lucid style.

Moriz Kaposi is, very appropriately, the author of

the section on xeroderma pigmentosum, which he first described in 1870. He deprecates the optimistic prognosis of curability of the disease of some dermatologists, and does not believe that a case has ever been cured.

The final monograph in the fifth volume is on dermatoneuroses, by H. Leloir, whose name is so well and favorably known in association with this important class of diseases of the peripheral nerves. It is one of the most concise yet complete *résumés* of our present knowledge of these diseases that a student of the subject can refer to.

The sixth volume is devoted to diseases of the respiratory organs. The opening section, on diseases of the nose, is by Dr. Prosser James, who divides the subject into external and internal diseases of that organ, the first mentioned being disposed of briefly, while the last mentioned are treated at greater length.

Dr. Jonathan Wright is the author of the chapter on diseases of the accessory sinuses of the nose, and Dr. E. J. Moure, of that on diseases of the nasopharynx and pharynx, both of which subjects are satisfactorily reviewed.

Dr. Albert H. Buck is the author of the monograph on diseases of the ear, in which he judiciously confines himself to a general sketch of the pathological changes which take place in the human ear, of the symptoms to which they give rise, of the available means to ascertain the nature and extent of these changes, and of the remedial measures to afford relief or produce a cure.

Dr. E. J. Moure is the author of the section on diseases of the tonsils. The author advises that the treatment of diphtheria should be based on the distinction between monomicrobic, polymicrobic or bacilloccocic, and bacillostreptococcic diphtheria, though he considers that antitoxine serum is indicated in all these forms.

The section on diseases of the larynx is from the pen of Dr. Francke H. Bosworth, who has included a great deal of information in a moderate compass.

Sir Thomas Granger Stewart and Dr. G. A. Gibson are the joint authors of the section on the diseases of the trachea and bronchial tubes.

The ætiology of bronchitis is written of from a nineteenth rather than a twentieth century standpoint, it would seem from the indifference shown to the microbic origin of the disease and the stress laid on climatic influence.

Dr. Winslow Anderson is the author of the monograph on diseases of the lungs, which does not include croupous pneumonia and pulmonary tuberculosis.

These volumes show a great deal of careful work, and on the whole afford a satisfactory presentation of the various diseases that are described in their pages.

*Atlas of the Diseases of the Skin*, in a Series of Illustrations from Original Drawings, with Descriptive Letterpress. By H. RADCLIFFE CROCKER, M.D., F.R.C.B., Physician to the Department for Diseases of the Skin, University College Hospital, etc., London. Fasciculus XVI. Edinburgh and London: Young J. Pentland. New York: Macmillan & Co., 1895. [Price, \$6 each part.]

THE sixteenth and final fasciculus of this *magnum opus* contains plate xiv, which shows the back of a patient affected with impetigo contagiosa gyrata, a rare bullous form of impetigo which closely resembles pemphigus contagiosus. In this case agar-agar cultures made from the fluid in unruptured bullæ produced a

practically pure culture of *Staphylococcus pyogenes aureus*. Plate lii portrays the face of a woman affected with myxœdema and a case of lentiginous pigmentation in a child. Plate liv illustrates the abdomen, loins, neck, and axilla of a woman who had acanthosis nigricans.

Plate lxxviii depicts the buttock, thigh, forearm, and hand of a patient who had that rare malady, mycosis fungoides. The patient was most benefited by a continuous bath in water containing hydrogen peroxide.

Plate lxxxviii represents three forms of folliculitis and some diseases of the surface of the tongue.

Plate xc illustrates several diseases of the nails.

A new plate illustrating pemphigus is sent in this fasciculus in lieu of plate xvii in the fourth fasciculus.

This part includes the title pages to the two volumes, the table of contents, the preface, and other material for the binder. The publishers are to be commended for the beautiful typographical and lithographical work which make this an *édition de luxe* in dermatology.

*Nouveaux éléments d'ophtalmologie.* Par H. TRUC, professeur de clinique ophtalmologique à la Faculté de Montpellier, et E. VALUDE, médecin de la clinique ophtalmologique nationale des Quinze-vingts. Tome premier. Avec 149 figures et une planche en couleurs. Paris: A. Maloine, 1896. Pp. viii-604.

THIS work will be completed in two volumes and it will be necessary to reserve the final opinion as to its merits until the appearance of the second volume; the impression gained, however, from the volume at hand is decidedly favorable. The authors modestly say that it contains a *résumé* of what has been written in many books, and that it will serve as a clinical introduction to the larger treatises on ophtalmology. We venture to say that for many readers, who are not debarred by the language, it will take the place of those monumental works in several volumes which are constantly referred to but seldom read. There are some original features of considerable value.

The part devoted to the work of the laboratory, pathological and bacteriological, is well written. The short chapters on the history of ophtalmology, on embryology, on comparative anatomy, and on physiology contain much that is interesting and not easily accessible. In some instances we note the French point of view, and it is welcome, for our eyes have been so long turned expectantly toward Germany for scientific results that we have overlooked the important work done in Paris. Javal and Tscherning at the Sorbonne, Panas and his assistants at the Hôtel Dieu, and the brilliant clinical work of the younger men at Quinze-vingts, maintain a high standard. Full justice, however, is done foreign authorities, for, if the French are Chauvinistic in other matters, in science they show no jealousy.

The last part of the volume is given up to the general pathology of the eye, including a rather inadequate chapter on tumors and an excellent discussion of the relations between the eye and general diseases and diatheses, in which, however, diabetes and nephritis are insufficiently treated of.

While we recognize the value of the work, it must be said that the arrangement does not give a result tending to the greatest simplicity and clearness; it is as if made up of separate monographs, involving repetition and confusion in reference. The illustrations are for the most part diagrammatic and are perhaps clearer than if

they had been more elaborate, but the drawings of the fundus in the chapter on ophthalmoscopy are by no means up to the standard to which we have become accustomed. A few typographical errors should be corrected in a future edition. An amusing instance of the French habit of appropriating words from other languages is the use of "shokes disc" instead of choked disc.

The second volume will contain the clinical matter. We shall await its appearance with interest.

#### BOOKS, ETC., RECEIVED.

In Sickness and in Health. A Manual of Domestic Medicine and Surgery, Hygiene, Dietetics, and Nursing, dealing in a Practical Way with the Problems relating to the Maintenance of Health, the Prevention and Treatment of Disease, and the most Effective Aid in Emergencies. By George Waldo Crary, M. D., Frederic S. Lee, Ph. D., Josiah Royce, Ph. D., Joseph Hamblen Sears, A. B., Samuel T. Armstrong, M. D., Ph. D., Alexander B. Johnson, M. D., William P. Northrup, M. D., Frank W. Jackson, M. D., Samuel Waldron Lambert, M. D., Frederick Peterson, M. D., Ph. D., Henry A. Griffin, M. D., Anna Caroline Maxwell, and J. West Roosevelt, M. D., Editor. New York: D. Appleton & Company, 1896. Pp. xvi-991.

A System of Medicine by Many Writers. Edited by Thomas Clifford Allbutt, M. A., M. D., LL. D., etc., Regius Professor of Physic in the University of Cambridge, etc. Volume I. New York and London: Macmillan & Company, 1896. Pp. xxxix-978. [Price, \$5.]

Burdett's Hospitals and Charities, 1896; being the Yearbook of Philanthropy. Containing a Review of the Position and Requirements, and Chapters on the Management, Revenue, and Cost of the Charities. An Exhaustive Record of Hospital Work for the Year, etc. By Henry C. Burdett, Author of Hospitals and Asylums of the World, etc. London: The Scientific Press (Limited). [Price, five shillings.]

Transactions of the Southern Surgical and Gynecological Association. Volume VIII. Eighth Session, held at Washington, D. C., November 12, 13, and 14, 1895. Published by the Association.

Proceedings of the American Medico-psychological Association at the Fifty-first Annual Meeting held in Denver, June 11 to 13, 1895. Published by the American Medico-psychological Association.

Medical and Surgical Reports of the Boston City Hospital. Seventh Series. Edited by George B. Shattuck, M. D., W. T. Councilman, M. D., and Herbert L. Burrell, M. D.

Reduced Period of Intubation by the Serum Treatment of Laryngeal Diphtheria. By Edwin Rosenthal, M. D., Philadelphia, Pa. [Reprinted from the *Medical and Surgical Reporter*.]

Gynecology at the Lane Hospital, San Francisco. By Clinton Cushing, M. D. (Read before the Medico-chirurgical Society of San Francisco, June 1, 1896.)

Indio. The Colorado Desert for Health. By Walter Lindley, M. D., Los Angeles, Cal. [Reprinted from the *Medical Record*.]

Alcohol in the Treatment of Rosacea. By R. Abrahams, M. D. [Reprinted from the *American Medico-surgical Bulletin*.]

De la Prothèse appliquée au traitement des empyèmes de l'antre d'Highmore. Par le Dr. Simon Dunogier, de Bordeaux. Bordeaux: G. Gounoilhou, 1896.

Blind Leaders of the Blind. The Romance of a Blind Lawyer. By James R. Cocks, M. D. Boston: Lee & Shepard, 1896. Pp. 3 to 487.

The Pathology of the Contracted Granular Kidney and the Associated Cardio-arterial Changes. By Sir George Johnson, M. D. Lond., F. R. C. P., F. R. S., Emeritus Professor of Clinical Medicine, etc. With Twenty-nine Illustrations. London: J. & A. Churchill, 1896. Pp. vi-62. [Price, \$1.40.]

Traité d'électrothérapie oculaire. Par le Dr. P. Pansier, d'Avignon. Avec une préface de M. le Dr. E. Valude, de la Clinique nationale ophthalmologique des Quinze-vingts. Paris: A. Maloine, 1896. Pp. iv-479. [Prix, 6 fr.]

Inefficiency of Milk Separators in Removing Bacteria. By Veranus A. Moore. [Reprinted from the Yearbook of the United States Department of Agriculture.]

Di una nuova particolarità nella tecnica dell'anestesia locale cocainea. Dott. Tito Costa. Comunicazione fatta al 2° Congresso Medico Regionale Ligure in S. Remo, Aprile, 1896.

The Anatomy of the Human Head and Neck, Graphically Illustrated by Means of Superimposed Plates. With Descriptive Text by Dr. Schmidt. English Edition by William S. Fournieux. New York: Thomas Whittaker, 1896. Pp. 4 to 16.

Whittaker's Anatomical Model. With Descriptive Text by Dr. Schmidt. English Edition by William S. Fournieux. New York: Thomas Whittaker, 1896. Pp. 4 to 16.

### New Inventions, etc.

#### A MODIFIED VAGINAL SPECULUM.

By ANDREW F. CURRIER, M. D.

THE accompanying cut shows a self-retaining vaginal speculum which a great deal of trial and experimentation has led me to be very well satisfied with.

The original suggestion was a French invention brought to this country a few months ago by Dr. W. M. Polk, with the blade and handle in one piece, and the blade set at nearly a right angle to the handle. It was reproduced by the Ford Instrument Company, was quite expensive (about fifteen dollars, I think), and on the several occasions when I made use of it was not entirely satisfactory. Even in very relaxed vaginae it failed to hold its position and would fall out in the most annoying way. It also failed with me to give the desired exposure of the vaginal vault and portio vaginalis. To combine the merits of the Edebohl's speculum, which is one of the very best for vaginal work with which I am acquainted, with the French instrument seemed to me desirable, and this was finally accomplished with the assistance and patience of the Ford Instrument Company.

The lower part of the handle remains unchanged. The grip is a mass of lead weighing thirty-two ounces, the shaft is tubular for the easy escape of fluids, and the lower extremity has a collar to which rubber tubing may be attached if it is desired.

Just above the grip the detachable blade is adjusted. It makes a tight joint with the handle, and is secured with a milled screw on either side, which may be loos-

ened with half a turn. Of course, the detachable character of the blade makes the instrument much more portable as well as easier to clean.

The blade is set at a very sharp angle, and I have never known it to fall out of the vagina. I have found, however, that the ordinary Edebohls blade is too small to admit of entirely satisfactory operation in very long

and voluminous vaginæ, and therefore have had a larger one made with the same relative proportions as the smaller one.

With these two blades, exchangeable at will, all the cases in which I have used them have been quite under control. The handle in question seems to me decidedly preferable to the tin bucket which is used with the Edebohls instrument. Another advantage of this instrument is that it may be bought at a much lower price than the French instrument, and, in my practice at least, it has proved decidedly preferable.

The dimensions of the instrument are as follows: Length of speculum, eight inches; weight of speculum, two pounds seven ounces; length of small blade, three inches and a half; length of large blade, four inches.

120 EAST THIRTY-FOURTH STREET.

## Miscellany.

**Antivivisection Legislation.**—At the fifty-fifth annual meeting of the Ohio State Medical Society Dr. James E. Pilcher read a paper regarding the antivivisection movement in the District of Columbia from which we quote the following remarks:

"This movement of the self-styled antivivisectionists has gathered so much momentum in its misdirected career of exaggeration and misrepresentation that the medical profession must, in self-defense, take a decided stand for the preservation of its own liberties and the best interest of suffering humanity. It is one of the unfortunate concomitants of all progress that certain of its advocates should proceed to unjustifiable extremes. Extremists are well enough in their way, and exaggeration is sometimes of advantage in attracting attention to a subject which might otherwise escape well-merited consideration. But when the extremist begins an effort to prohibit that which is essential to the progress of civilization and the highest phases of philanthropy, it is time to call a halt.

"There is no profession in which humanity is so much a part of the daily life of its practitioners as medicine; no class of mankind so conspicuous for gentleness, tenderness, and charity as medical men; no body of

individuals of whom it could be so truly said that they would inflict pain upon no living being as the practitioners of the healing art. The absurdity of placing such persons in the attitude of defense against an accusation of cruelty or inhumanity of any kind is evident to every one.

"It has been admitted from the beginning of history that the lower animals are designed to subserve the interests of mankind. The most rabid antivivisectionist will masticate his cutlet of veal or his shoulder of lamb, all regardless of the joyous young life that has been rudely terminated merely to gratify the animal appetite of the alleged defender of our dumb animals. We have no record of the refusal of the quasi-humanitarians to partake of the viands which are displayed in the butcher's shop for the gratification of the gourmand; we have no record of any attempt, legislative or otherwise, to close the establishments of the dealers in animal flesh. The sportsman inflicts untold agony upon the victims of his prowess, but we hear of no movement looking to the prohibition of hunting; on the contrary, most of our States by legal enactment designate certain seasons in which the chase is expressly allowed, the prohibition of the sport in other parts of the year being due, not to a desire to save the game from suffering, but rather to provide for the more prolific reproduction of the species, so that a greater number of victims may be available for the disciples of Nimrod during the following season. The antivivisectionist nestles luxuriously in his furs and his wife waxes gorgeous in her headgear garnished with the plunder of feathered songsters—both the spoil of the rapacity and cruelty of man; while the shoe trade, based entirely upon the products of the death of millions of God's most harmless of creatures, is prosperous in the extreme.

"The horse which he drives, the capon with which he delights his palate, and the beef or mutton which forms his daily food are all distorted examples of their species, deformed and degraded by painful operations in order to adapt them better to his service; but where is the record of his refusal to use them?

"When the antivivisectionist becomes a strict vegetarian; when he avoids all amusements resulting from animal slavery or suffering; when he clothes himself entirely in garments of vegetable and mineral composition; when he suppresses all practices, sportive and mercenary, by which pain is inflicted upon animals, he may properly begin to inquire into vivisection with a view to ascertaining whether it is humanitarian or cruel. I say he may begin to inquire, for if he is honest and unprejudiced, he will go no further than the beginning, since he will immediately discover that of all practices, altruistic and humane in the highest sense of the words, vivisection is one of the most notable.

"In the war of the rebellion, 3,273 out of 3,717 cases of wounds of the intestines were fatal. It was demonstrated a few years ago by experiments on dogs that abdominal section and intestinal suture in such cases was a feasible and successful operation, and the operative procedure was experimentally elaborated, so that by it the mortality in gunshot wounds of the intestines has been reduced from ninety to ten per cent. In other words, if these vivisectional experiments had been performed before the war, over 3,000 men might have been saved to the country with injuries not sufficient even to require a pension.

"The brain which, as well as the abdomen, was formerly regarded as forbidden ground to the surgeon, has,

by the vivisection experiments of Ferrier and others, been brought within the realm of curative art. In a single year, out of 165 cases of epilepsy collected by Echeveria, 75 patients were successfully cured, and in the same period Macewen, of Glasgow, saved no less than 90 human lives by following out the cerebral indications discovered by Ferrier in his experiments upon living lower animals.

"To relate fully and adequately the contributions of vivisection to the means of supporting the sick, relieving the suffering, and rescuing the perishing would require volumes. The work of Aristotle, Realdus Columbus, Andreas Cæsalpinus, William Harvey, and Marcello Malpighi in discovering the circulation of the blood—a matter not only of medical, but of general history as well—was entirely conducted by experiments upon lower animals. The experiments of Vesalius, Hooke, and Lower gave us artificial respiration, to which we owe so many thousands of lives every year. Transfusion of blood was directly the offspring of vivisectional experiment. The relief of large numbers of kidney affections was demonstrated only a few years ago through animal experiments by Simon at Heidelberg. Indeed, the entire system of antiseptic and aseptic surgery, the greatest humanitarian triumph in the world's history, is based upon the practice of vivisection. Medicine owes as much to it as surgery, for the bacillus of anthrax, the bacterium of tubercle, the micro-organism of diphtheria, the spirillum of relapsing fever, the streptococcus of erysipelas and puerperal fever, and many other specific agents in disease have been discovered entirely through experiments upon lower animals. The antitoxine treatment of diphtheria, the Pasteur inoculation cure of hydrophobia, the prevention of small-pox by vaccination, and many others of the most important therapeutic procedures of modern medicine are due to vivisection, while still many more are the subjects of observation, which beyond doubt will ultimately result in the discovery of curative procedures.

"Said an eminent oculist, now dead: 'I have spoiled a bushel of eyes in learning to treat one.' Said a celebrated English surgeon not long ago: 'Doctor, you have a more sensible method in America in learning intestinal surgery on dogs; we are not generally allowed to vivisect here, and I have filled graveyards full of people in learning intestinal surgery on humans.' The unspeakable advantage to be gained by the practice of operative methods upon the lower animals in order to gain the experience and dexterity which will render more successful operative work on human beings can not be estimated. The perfection of technics, the observation of the conduct of wounds, familiarity with topography, and the acquirement of the *factus eruditus* in handling the organs and parts must be gained by actual practice, and the death of a thousand rabbits is but a small price to pay for the privilege of saving a single human life.

"Moreover, while vivisection experiments are always beneficial they are never cruel. Even were the medical student the heartless creature represented by the anti-vivisectionists, he would prefer, for his own convenience, to silence the cries and subdue the struggles of his subjects by an anæsthetic; and, as a matter of fact, a desire to avoid the infliction of suffering causes him to render the little animal which contributes to the welfare of mankind entirely insensible during his work.

"All this emphasizes the deceptive and incorrect character of the efforts to embarrass, if not prohibit, the future of these genuinely philanthropic as well as scientific studies. The dangerous movement looking to this

end, initiated in the District of Columbia, has met with astounding success, and it behooves all true lovers of scientific progress to unite in the attempt to prevent the enactment of the bill now before the United States Senate for this purpose; for, should this movement be successful in the District, it would not only put an end to most important work in various scientific departments of the government and the medical schools of Washington, but it would be the beginning of a movement jeopardizing scientific study throughout the entire Union."

"Whereas, far more unnecessary pain is constantly being inflicted upon the lower animals for sport and for gain than in biological and pathological laboratories; and,

"Whereas, no evidence has been presented by those who advocate restrictive legislation showing that abuses exist in the District of Columbia; and,

"Whereas, results of great practical importance have been obtained by experiments on the lower animals made in the government laboratories in the District of Columbia. Therefore be it

"Resolved, That the American Medical Association earnestly protests against the passage of Senate bill No. 1,552, entitled A Bill for the Further Prevention of Cruelty to Animals in the District of Columbia, or any modification of this bill, unless it shall first be shown by an impartial investigation that cruel and unnecessary experiments are being performed in the District of Columbia, and that existing laws do not provide suitable punishment for cruelty to the domestic animals.

"This is a matter of so great importance that it is clearly the duty of the medical profession of the State of Ohio also to put on record what I know to be its unanimous opinion with regard to the subject, and to bring the matter to an issue I move the adoption of the following resolutions:

"Resolved, That the Ohio State Medical Society earnestly joins in the protest of the American Medical Association as expressed in the resolutions adopted at the recent meeting of that representative body of American physicians and surgeons held in the city of Atlanta.

"Resolved, That a copy of these resolutions be sent to the Senators and Representatives of the State of Ohio in the Congress of the United States, and that they are hereby requested to use their influence in opposition to the proposed legislation, 'unless it shall first be shown by an impartial investigation that cruel and unnecessary experiments are being performed in the District of Columbia, and that existing laws do not provide suitable punishment for cruelty to domestic animals.'"

The following amendment, proposed by Dr. L. B. Tuckerman, of Cleveland, was accepted by Dr. Pilcher, and the resolutions as amended were unanimously adopted:

Resolved, That a delegate be appointed by this society to go to Washington and interview the Senators and Representatives in person in behalf of these resolutions, and that one hundred dollars be appropriated to pay his expenses.

**The Complications and Treatment of Erysipelas.**—In an article on this subject in the *Journal des praticiens* for June 29th the writer calls attention to the fact that, although erysipelas of the face is ordinarily benign, in certain forms the disease may present a number of local or general complications.

Suppuration and gangrene of the invaded tissues are seldom observed, he says, except in those who suffer from

diabetes, Bright's disease, alcoholism, and hepatic affections. However, intense erysipelas may cause partial sphacelus by mechanical compression. Relapses of this disease are sometimes so frequent as to constitute a veritable complication, although they are generally benign. In time, however, they may determine a true elephantiasislike infiltration of the tissues. Sometimes, also, a relapse which follows a series of benign attacks is accompanied by grave infectious symptoms.

Among the general complications, gastro-intestinal catarrh is almost habitual, although it is not serious, except in certain biliary forms with symptoms resembling those of a grave icterus. Occasionally the entire digestive tube is invaded, and abscess of the liver has also been noted. Angina, which often precedes, accompanies, or follows erysipelas, is sometimes very intense and is accompanied by symptoms of gangrene. When it spreads to the larynx and to the roof of the mouth it is always very grave. An intense rhinitis also warrants a very serious prognosis. In such cases, says the writer, oedema of the glottis or erysipelatous pneumonia or broncho-pneumonia is to be feared.

The forms of erysipelas with generalized streptococcic infection are accompanied by a grave adynamic general condition. They may be complicated with simple or ulcerative endocarditis, meningitis, myelitis, acute hæmorrhagic nephritis, suppurative arthritis, etc. These various complications are, however, rather rare.

In spite of the intense palpebral swelling, says the writer, erysipelas generally spares the ocular globe; but the possibility of keratitis, iritis, and hypopyon should be borne in mind. From a prognostic point of view there should always be taken into consideration the real gravity which is generally presented by the epidemic forms of erysipelas, those developed by direct contagion.

According to the writer, the treatment is usually very simple. Milk should be given copiously, also coffee and saline purgatives. Wine of cinchona, given in amounts of six ounces or more during the day, is a valuable remedy, as Leudet and Jaccoud demonstrated. Alcohol should always be prescribed for alcoholics. Where there are serious adynamic symptoms internal remedies seem useless and even dangerous. This is especially true if albuminuria exists, since it indicates a possible defect in renal elimination, and the employment of such remedies is to be distrusted. In these cases, according to Galliard and Legendre, cold baths constitute the best treatment. Visceral complications are, according to the latter, an indication rather than a contraindication. Albuminuria, particularly, will be favorably modified. Not more than six baths a day should be taken, and their temperature should be from 68° to 72° F., and their duration from ten to fifteen minutes.

As a means of local treatment in simple cases, compresses saturated with an infusion of elder berries or with boracic acid water will generally give sufficient relief. In cases of very great tension the following preparations will be found useful:

1. Sodium salicylate.....	60 grains;
Cold cream.....	3 ounces.
2. Salicylic acid, } each.....	60 grains;
Borax, } .....	16 ounces.
Boiled water.....	150 grains;
3. Sodium salicylate.....	16 ounces.
Boiled water.....	

When erysipelas breaks out in a bad subject, for instance, in cases of Bright's disease, diabetes, or alcoholism, when the patches spread rapidly and present a tend-

ency to sphacelus, Vidal, says the writer, recommends a more energetic local treatment either by spraying with corrosive sublimate or with traumaticin and ichthyol.

Spraying with corrosive sublimate requires delicate handling; if it is badly done it may leave indelible cicatrices; the technics of the second treatment is much more simple, and the following formula is recommended:

Ichthyol, }  
Traumaticin, } ..... equal parts.

The erysipelatous swelling may be kept within limits by painting with this liquid three or four times a day, in such a way as to maintain the coating of traumaticin intact. In two days the erysipelas is generally arrested. The painting is continued for forty-eight hours after the inflammation has completely disappeared.

**A Medical Excursion.**—At a recent meeting of the American Laryngological Association Dr. J. W. Gleitsmann made a proposition in regard to an excursion to the International Medical Congress which is to be held in Moscow in August, 1897.

His plan is to combine a trip to Norway and St. Petersburg with the visit to Moscow, starting from Hull, in England, about the middle of July and arriving in Moscow about the middle of August. The trip would include the regular tourists' excursions along the Norwegian coast with its beautiful fjords to the North Cape, thence back to Trondhjem, and from there by rail to Christiania. A short trip could be made to the famous Trollhoettan Falls on the way to Stockholm, from which place steamers sail to Abo, in Russia; thence by rail to St. Petersburg. If a sufficient number of ladies and gentlemen—from sixty to seventy—join the excursion, they would probably be able to have a steamer to themselves.

This trip can be comfortably made within a month, and Dr. Gleitsmann gives the assurance that the expense would not exceed a hundred and fifty dollars. This includes steamboat berth and meals from Hull to the North Cape and back to Trondhjem, also a first-class railroad ticket from Trondhjem to St. Petersburg, but not hotel or other expenses.

Dr. Gleitsmann states that he mentioned this trip to French and English physicians, and they were very favorably impressed with the plan and promised to get a number of physicians to join the party. He hopes that as much interest will be shown here in the proposed pleasure trip, as it affords a rare chance to see some of the most beautiful European scenery. Definite arrangements will be made during the latter part of the year, and all those who desire to join the excursion are requested to apply to Dr. Gleitsmann, at No. 46 East Twenty-fifth Street, who will give any information required in regard to the trip.

**A Case of Knife-swallowing, with Successful Gastro-tomy.**—The *Indian Medical Record* for May 16th contains the following account of a case which came under the observation of Mr. A. N. Chaudhrie at the Sadar Dispensary in Hamirpur: The patient, a man twenty-seven years old, tried to prove himself a successful juggler by swallowing a blunt knife, which measured twelve inches in length and was three quarters of an inch broad; a portion of the knife protruded about an inch out of the mouth. He then tried to introduce a second one, leaving the first *in situ*; the result was that it tilted the first one, which slipped down into the stomach. The man was fairly muscular. He suffered acutely

from pain in the abdomen, where one end of the knife could be felt on manipulation. During his stay various methods were tried, such as emetics, inversion, etc., the failure of which left no other alternative but to decide for gastrotomy.

The man was kept fasting for about twenty hours, when the abdominal region was washed with antiseptics, and the patient was chloroformed. The common incision for gastrotomy had to be abandoned, and an incision about three inches in length was made about two inches from the navel, the lower margin of which was almost on the level of the navel. This incision had to be made owing to the fact that the end of the knife was at that level. Careful dissection of the different abdominal parietes and their division gradually exposed the peritonæum, which was slit open on a director; the gut, which was exposed in the wound, was pushed aside, and the end of the knife inside the stomach was brought out of the wound. Lembert's sutures were applied and it was slit open, and the knife was found lying firmly jammed across the stomach, and was extracted with some difficulty. The bleeding was slight and was stopped by a little pressure. The sutures were tightened and the stomach was sutured with catgut and replaced in the abdominal cavity, the peritonæum was drawn closer (but not sutured), deep sutures were applied, and the skin flap was sutured with catgut. Dry dressings were applied, and the man was removed to bed.

The operation lasted three quarters of an hour. Morphine was injected hypodermically. The man was fed by enemata of milk mixed with pepsin and zymine, until April 13th, on which date he was allowed to have liquid nourishment by the mouth. During all this time his temperature kept normal, the dressings were removed on the seventh day for the first time, and the wound was found to be practically healed.

There was excessive thirst for the first five days, and, as no ice could be obtained, the author tried half a grain of menthol with betal, which, he says, relieved the thirst in a remarkable manner.

Commenting on the case, he says that if the incision had been made considerably lower down, great difficulty would have been experienced in extracting the knife; furthermore, he draws attention to the effects of the menthol, and to the fact that the peritonæum was not sutured, and he thinks that he has no occasion to regret this omission.

**The Treatment of Measles.**—In the *Lancet* for June 20th Mr. A. Dunley Owen remarks that during the early months of this year an epidemic of measles of a severe type visited Northampton and the surrounding district, and there was an unusually high mortality from this disease, chiefly, he believes, from concurrent bronchial and pulmonary inflammations. Of the cases that fell to his share he took notes of over three hundred with a mortality of only four, of whom one died from capillary bronchitis three hours after he was called in, and the others were under two years old and succumbed to bronchopneumonia. He attributes this low rate of mortality to the method of treatment that he has invariably adopted—namely, to order jacket poultices, to be changed every three hours, as soon as any indications of measles show themselves and before the rash appears, and he thinks this has been beneficial, for death has occurred only in those cases in which the mother discontinued the poultices after the first application, or, as in one case, thought proper not to poultice at all. The only medicinal treatment adopted has been ipecacuanha wine

with acetate of ammonia, with a boric-acid wash for the eyes in those cases which were complicated by catarrhal inflammation of the lids. Stomatitis occurred in about one half of the cases and invariably yielded to the application of a saturated solution of chlorate of potash to the inside of the mouth, the children being too young to use a mouth wash. Convalescence proved slow in nearly all of these cases.

It is a curious fact, says Mr. Owen, that children living in towns gain strength far more rapidly than those in the surrounding country districts, and he thinks it is owing to the fact that town workers earn higher wages, thus enabling them to procure a better diet for their children.

**Splenic Extract in Therapeutics.**—Dr. W. Cohnstein, of Berlin (*Allgemeine medicinische Central-Zeitung*, 1896, No. 43; *Therapeutische Wochenschrift*, June 14, 1896), having found, like Danilewsky, that the use of a watery extract of the ox's spleen, whether given by the mouth or subcutaneously, gave rise to a notable increase in the number of the red blood-corpuscles in dogs and rabbits, has proceeded to employ it therapeutically. He reports upon its use by several physicians in twenty-three cases. In one of them the disease was leucæmia; the others were examples of anæmia or chlorosis. In the case of leucæmia there was only a transitory effect observed, not really therapeutical. On the other hand, in the majority of the cases of anæmia and chlorosis the action of the extract was very striking. The first signs of improvement were seen in the subjective symptoms of debility, loss of appetite, constipation, headache, and dysmenorrhæa. Objectively, the pallor disappeared, and often there was an increase of the hæmoglobin or of the number of the red blood-corpuscles. In many cases the patients gained flesh notably. In many others there were no objective signs of improvement. In no instance was any unpleasant effect observed.

The splenic extract employed by the author was one known by the trade name of *eurythrol*. It is a watery extract to which salt has been added, partly to preserve it and partly to give it a better flavor. It is described as resembling Liebig's beef extract. The amount to be given daily is from one to two teaspoonfuls, dissolved in hot water.

**Guaiecin in the Treatment of Pulmonary Tuberculosis.**—In the *Centralblatt für innere Medicin* for June 20th, Dr. J. Strauss, an assistant physician in Professor von Noorden's division of the Municipal Hospital in Frankfurt on the Main, reports upon the use of this substance in the treatment of pulmonary tuberculosis. He first remarks that guaiecin is a pyrocatechin-monacetic acid,  $C_6H_4 \begin{matrix} OCH_2COOH \\ OH \end{matrix}$ , obtained by introducing the carboxyl group into guaiacol. His particular object in the employment of the drug was not to ascertain what remedial effect it had, for he takes it for granted that whatever curative action is attributable to any one of such substances as creosote, guaiacol, guaiacol carbonate, guaiecin, etc., must be credited to the others also; he had rather in view an investigation as to the incidental effects of guaiecin, particularly on the stomach and on the kidneys.

The drug was used in the cases of seventy phthisical patients in all stages of the disease, in doses of about seven grains, several times a day. It is described as a tasteless powder. Sixty-one of the seventy patients took it without the slightest disturbance of the digestive

apparatus, although in six of them the creosote treatment had previously had to be discontinued on account of impairment of the appetite, nausea, eructations, or vomiting. The following were among the unpleasant symptoms that the author thinks may have been due to the drug: Impairment of the appetite occurred in two of the cases. Four patients had loss of appetite, nausea, and vomiting which they ascribed to the medicine, but which did not subside on the discontinuance of its use. In two of these four patients the amount of hydrochloric acid in the gastric juice was normal, in one it was too small, and in one it was too large. Two patients were attacked with abdominal pain and diarrhea every time they took guaiaceticin, but the attacks soon subsided when the use of the drug was discontinued. One of these patients had had similar symptoms, and in greater severity, as the result of taking creosote. Of all the seventy cases, therefore, there were only two in which gastro-intestinal disturbances could with certainty be imputed to the use of guaiaceticin.

Headache, vertigo, and pronounced weakness showed themselves in one case on the fourth day of the guaiaceticin treatment, and persisted for five days, when, on the use of the drug being suspended, they at once disappeared.

Albuminuria did not come on in any of the cases, and pre-existing albuminuria was not aggravated by the treatment.

On the whole, the author thinks that, as regards collateral effects, guaiaceticin produces them to a lesser extent than either creosote or guaiacol carbonate.

**A Remarkable Case of Keloid** is reported in the *Monatshefte für praktische Dermatologie* for June 15th by Dr. Ravogli, of Cincinnati, and a very clear portrait of the patient is given. The growth seems not to have been of traumatic origin and the man, a Kentucky negro, had never had syphilis. The most noticeable part of the growth sprang from the region between the chin and the throat and extended backward on the neck.

**Ferrostyptin.**—In the *Therapeutische Wochenschrift* for June 21st this drug is described as a yellow crystalline powder introduced by Dr. A. Eichengruen and made by Dr. L. C. Marquart, of Beuel. It is freely soluble in water, but insoluble in cold alcohol or ether. It is brought forward as a substitute for chloride of iron as a styptic, and is said to have the advantages of being unirritating and antiseptic, which make it particularly suitable for gynecological practice, also in rhinology and dentistry.

**Photography of the Human Stomach by the Roentgen Method.**—In an article on this subject in the *Boston Medical and Surgical Journal* for June 18th, Dr. John C. Hemmeter states that Dr. Becker, of Berlin, made use of the property of solutions of not allowing the Roentgen rays to penetrate in order to photograph the stomach and a loop of intestine of a guinea-pig by distending both with the liquor plumbi subacetici of the German Pharmacopoeia. In the photograph the only parts of the abdominal contents that are visible are the parts that contain the lead-acetate solution. It can not be affirmed, however, says Dr. Hemmeter, that the outlines of the stomach and intestinal loop are well defined, which is explained, perhaps, by the fact that the solution leaked out into the abdominal cavity.

To obtain a photograph of the human stomach a solution having the two following properties is neces-

sary: 1. It must not injure the stomach of the subject to be photographed. 2. It must be impenetrable to the Roentgen rays. Then it will be important to observe in what dilution these solutions may yet refuse penetration to these rays of light.

Dr. Carl Wegele, of Koenigsborn, Westphalia, commenting upon Becker's experiment, suggests the introduction of his spiral electrode into the stomach in such a manner that it should come to lie along the greater curvature of the stomach. A small coin is suggested to be placed over the umbilicus. Both the metal of the electrode and the coin would show in the photograph and thus some idea of the location of the stomach might be obtained. This would, however, says Dr. Hemmeter, give no impression of the size of the organ, as the metal of the electrode would in favorable experiments map out the greater curvature only. Although the duration of exposure for the Roentgen method has been much shortened by the improved methods of the physical laboratory of the University of Jena, the plan to determine the location and size of the stomach by the Roentgen photography can hardly be considered anything but circuitous.

The author thinks that a rapid and most reliable method of determining the location of the stomach is by Einhorn's electro-diaphany; and that its capacity and also its location can be readily ascertained by the use of his intragastric deglutible elastic-rubber bag.

The liquor plumbi subacetici used by Dr. Becker, he says, is not a solution of simple plumbic acetate, but contains also oxide of lead in the proportion of three of the former to one of the latter; besides being poisonous, it acts upon mucous membranes like a corrosive. Dr. Hemmeter does not consider the use of the Roentgen method, on account of its complexity and long duration of exposure, practically useful for determining the size and location of the stomach; if, however, one wishes to experiment with it to ascertain whether there is any value in it, he suggests that the solution of plumbic acetate be injected into his intragastric stomach-shaped rubber bag, which can be made strong enough to hold a sufficient quantity of the solution to distend the adult stomach, and at the same time it can be swallowed easily or pushed down, after it is folded over a thin oesophageal tube. When the bag, which has exactly the shape of the stomach, has reached the cavity of the organ, the plumbic-acetate solution can be slowly filled in through the mouth by means of the oesophageal tube until the bag is distended far enough to closely apply itself to the gastric walls. The umbilicus might be marked by a coin, as suggested by Wegele. A photograph taken in this manner, continues Dr. Hemmeter, would give not only a part of the stomach, but the entire organ, and show its location and size. After the exposure the solution of plumbic acetate would have to be removed by aspiration, for which a stomach pump would be useful for speedy evacuation.

**Rigors in Children.**—In studying this subject, Mr. Gerald R. Baldwin says in the *Lancet* for June 13th that he has employed valuable evidence contained in the surgical case books of the Hospital for Sick Children, Great Ormond Street. They extend over a period of seven or eight years and embrace nearly every variety of surgical disease seen in children. But although the material has been collected only from the surgical notes he has found many cases in which one of the acute specific fevers played a chief or subsidiary part. Before

quoting from the collected statistics, he says, it is as well to consider with what diseases rigors are commonly associated in adults and what are the other symptoms which most frequently accompany them. Certain acute specific fevers, and more especially cases of acute pneumonia, are commonly ushered in by a rigor. When extensive inflammation advances to suppuration one or more rigors may occur. In septic poisoning (sæpæmia) and septic infection (septicæmia) they are not uncommon, while they invariably accompany pyæmia. Of the accompanying symptoms pyrexia is essential; no shivering fit can be truly termed a rigor unless the temperature rises above the normal. The other symptoms depend largely on the nature of the disease; but if it is of septic origin there are generally great bodily depression, rapid, feeble pulse, dry tongue and lips, with, in many instances, vomiting, profuse diarrhoea, and muttering delirium. If the disease is pyæmic, secondary abscesses will be present in the subcutaneous tissues, joints, or viscera.

Rigors occur with extreme rarity in children, says the author. Out of a hundred and thirty cases rigors are mentioned in five only, while one case is said to have begun with shivering and in another frequent shiverings are recorded. The diseases selected for investigation have been chiefly of septic origin; but, in addition to these, he has included others, such as acute specific fevers beginning in the surgical wards and hyperpyrexia of doubtful origin, in which rigors may occur in adults. Roughly classifying the cases they arrange themselves into the following groups: acute abscess, cellulitis, hyperpyrexia, acute specific fevers, complications of mastoid suppuration, acute arthritis, acute periostitis, and acute epiphysitis.

From the statistics collected and the cases quoted by Mr. Baldwin he concludes that rigors are extremely uncommon in children, even in diseases which are acutely septic in character. On the other hand, convulsions are also uncommon in children. In a hundred and thirty cases he has found only five in which rigors occurred—i. e., once in a case of lateral thrombosis, the child being nine years old; once in a boy aged six years and a half, who died from pyæmia following acute abscess; once in a case of tuberculous meningitis occurring after tuberculous dactylitis in a child aged three years; once in a boy aged three years, who had acute periostitis of the tibia; and once in a child aged six years, the rigor being of doubtful origin. Two of these cases ended fatally. In five cases there was a history of convulsions, once in a child aged eleven months, with cellulitis of the foot; once in a case of cellulitis of the thigh and broncho-pneumonia, the child being one year old; once in a child aged two years and a half suffering from acute arthritis; and twice in children with acute periostitis, aged respectively two years and nine months and three years and nine months. The majority of the cases collected might have been accompanied by rigors in adults.

If, says Mr. Baldwin, as is generally supposed, the shivering in a rigor is caused by contraction of the superficial arterioles induced by irritation of the vaso-motor centre by various poisons in the blood, the cause for the extreme rarity of rigors in children is probably to be found in a less perfect development of that centre in them than in adults. The frequency of hyperpyrexia from comparatively trivial causes is another clinical fact which lends its weight to this suggestion. It may be safely concluded then, he says, that rigors are very rare in children, and almost unknown under three years of

age; and that convulsions very rarely take the place of rigors even in infants.

The author thinks that rigors are not of very great clinical value in studying the diseases of childhood. Before the age of seven or eight symptoms apart from signs can never assist so clearly in diagnosis as in older patients. The facial expression, manifestations of pain, and even the pulse itself seldom give the surgeon perfectly reliable information. But rigors may mislead him more than any other manifestation of disease. As a rule, he says, they point to severe infection, and if oft repeated generally to septic infection, but their presence or absence rarely assists in differential diagnosis. To take one instance from among many. In an adult with a profuse and fetid discharge from the ear the occurrence of rigors, especially if associated with other symptoms, such as vomiting and optic neuritis, points to lateral thrombosis.

Why one child has rigors and another has not it is impossible to say. The great fact that these cases appear to point out is that in diagnosis only a minimum amount of weight can be given to the absence or presence of rigors in children.

**Indian Hemp.**—In an editorial in the *Indian Lancet* for May 16th the writer gives a description of the effects of this plant, which is consumed in enormous quantities in the East. In small doses it quickly relieves pain and induces sleep. In larger doses it produces the following effects: Shortly after taking a full dose a pleasant state of intoxication ensues. The consumer perpetually talks, giggles, and sings. Ideas of a delightful kind pass rapidly through his mind, and he is possessed with a feeling of complete happiness and contentment. After a time sleep sets in, generally accompanied by pleasant dreams. But if the dose is excessive, or if the individual is peculiarly susceptible, the consequences are such as to prevent a repetition of the indulgence.

The following vivid description, says the writer, is given by Dr. H. C. Wood of the effects he suffered from an overdose of this drug: A few hours after taking it he was writing a prescription when he became perfectly oblivious to surrounding objects. He continued to write, however, and, on looking up and seeing the patient lying in bed, thought that he had been many hours writing the prescription, and he apologized for remaining so long. He then returned home in a state of ecstatic happiness. He laughed and made comic gestures and imitated the motions of a violinist. He knew he was acting foolishly but could not control himself. This condition lasted for half an hour, and then a change set in. He felt uneasy and his limbs became numb, and he walked constantly about the house. His mouth and throat became painfully dry, and he experienced a strange feeling in his legs, as though they were not a part of his body. A foreboding, an undefined, horrible fear, as of impending death, took possession of him, and he sent for a physician. He had lost all power of measuring time. When the physician arrived the patient was put to bed, but the symptoms grew intensified, and he felt himself mounting upward and expanding until he filled all space. He himself says, "I have never experienced anything like the fearful sense of almost hopeless anguish and utter weariness that was upon me."

This drug, continues the writer, is a native of Western and Central Asia, although it is cultivated in many parts of Europe. The Indian variety only is used in

European medicine. It has two principal forms, one consisting of dried leaves and small stalks, which is called bhang or siddhi in Hindustani, and hashish in the Arabic tongue; the other consists of the flowering shoots, and is called guaza by London drug brokers.

Although hemp is such a powerful drug, it is said not to be fatal, even in the largest doses. The odor is rather pleasant and the taste scarcely perceptible, and for this quality, says the writer, it lends itself, like arsenic, to criminal purposes. In India it is smoked both by Mahomedans and Hindus, either alone or with tobacco. It is also taken as an infusion. The commonest way of using it, however, is in a sweetmeat of a green color, which is composed of flour and various ingredients. Although its usual effect is the production of quiet happiness, and although it is said, like opium, to diminish crime, it sometimes produces furious delirium and renders the consumer perfectly reckless. The assassination of Justice Norman, for instance, in Calcutta, on the steps of the town hall, was perpetrated by a man under the influence of hashish. The Afghan chief, also, who murdered Dr. Forbes, in 1848, was known to have been intoxicated for days previously with charas or bhang. When the drug is consumed for any length of time it produces trembling and great muscular weakness. And a strange effect of it, occasionally, is a most ravenous appetite, which no quantity of food is capable of appeasing. But the astonishing effects produced in the warm East are never seen in colder England.

The use of hemp, says the writer, may be morally indefensible, nevertheless it serves most useful purposes. Some intoxicant appears to be a necessary food for the human nervous system. Hemp is, therefore, an excellent substitute for alcohol among the totally abstaining Mahomedans. It also enables the over-populated Asiatic countries to pull through their frequent famines in a way that would be impossible with Englishmen. And if we judge by the inoffensive Hindu it can not be said to be morally deleterious.

The use of bhang is as old as the hills. The ancient Chinese herbal called Rh-ya, written about the fifth century B. C., notes that there are two kinds of plant—one producing flowers and seeds, and the other flowers only. Many early Hindu works on medicine also, such as the Susruta and Charaka, describe hemp as a potent remedy for certain ailments; while Herodotus states that in his time it grew in India, and articles of clothing were made from it. The Scythians, he said, were in the habit of using it in their baths. They placed the seeds on red-hot coals, and exposed their bodies to the vapor. Early in the Middle Ages the use of bhang spread from India through Persia to the Arabians, but it was not until the sixteenth century that it was introduced into Europe. It did not take there, however, and during Napoleon's eastern expedition it was described as a new discovery by two French scientists. Thirty years later, in consequence of Dr. O'Shaughnessy's experiments in India, hemp became a permanent and valued addition to the British Pharmacopoeia. The famous care-destroyer of the Greeks was, according to Royale, nothing else than Indian hemp. It has furnished our language, continues the writer, with rather an ominous word—assassin, derived from hashishin, the name of a band of Mahomedans whose murderous deeds terrified the Crusaders, and who were so called from the fact that they used hashish in their religious rites. As for stopping the use of bhang by a royal commission, the writer says, we might as well try to keep swallows from building

nests. Considering the antiquity and universality of its use, it is impossible not to conclude that hemp is as necessary to the Mahomedan and Hindu as tobacco or beer is to the Briton. And the balance of evidence points to its comparative harmlessness.

**A Plea for Moderation in Statements regarding the Contagiousness of Pulmonary Consumption.**—In the *Boston Medical and Surgical Journal* for June 25th there is an article on this subject by Dr. Vincent T. Bowditch, of which the following is an abstract:

Recent events have impelled me to say a few words with the hope that by discussion of the subject we may have some influence directly or indirectly upon the community, especially upon the laity, in checking what has of late frequently seemed unnecessary alarm about the contagiousness of tuberculous diseases, especially in its pulmonary form.

In what I am about to say I trust that I shall neither seem to disparage the great advance in medical knowledge due to bacteriology nor to discourage in any way all reasonable efforts to prevent the spread of tuberculosis. I firmly believe that in another generation we shall see a diminution in the general death-rate from this disease, largely due to the precautions which are now so earnestly advocated by the mass of the profession. I only wish to protest against the unreasonable and often, as I deem it, cruel attitude taken by the laity and even by physicians in their desire to prevent the spread of the disease.

Not many weeks ago the people in Boston were treated in their local papers to hot discussions which have been carried on at the city hall relative to the proposed enlargement of a certain institution in the suburbs for the shelter of poor consumptives.

I have been surprised and even shocked to read the statements of some medical men at these hearings, to say nothing of the extravagant words of members of the laity—mostly composed of people living near the institution—who, in their desire to rid themselves of what seemed to them an objectionable neighbor, have given vent to most unwarrantable statements which serve to give the public an unnecessary alarm and create that state of constant apprehension which I firmly believe is a potent factor in producing disease.

The only excuse that I can conceive of for the marked opposition to this special institution is that at one time it was not conducted as a well-regulated hospital for consumptives should be, and that before we knew the importance of destroying the chief source of infection—namely, the sputa—patients were allowed to expectorate upon the grounds about the building, a method which, I have lately been told by one of the trustees, has been absolutely prohibited on pain of dismissal at the first offense.

Not long after these statements had appeared in the papers, I was asked by a layman my opinion upon the subject of the contagiousness of consumption. I told him that doubtless it was a contagious disease under certain conditions, but that with certain precautions, chiefly in the strict care of the sputa, the dangers from contagion were reduced to a minimum. It then came to light that he was one of the opponents of the institution about which such a controversy had occurred, and he almost angrily turned to me and said, "It is abominable that such hospitals should be allowed anywhere in our midst. They are a source of danger to all!"

The gentleman seemed to be oblivious of the fact that these same consumptive patients confined in the walls or in the grounds of the institution were an infinitely less source of danger than if allowed to roam at large, spitting in the street cars, public places, or even in their own homes. His position represents that of thousands who hold the same unreasonable views, and who in their fear of contagion forget the sympathy and kindness due to those who are suffering from consumption; and for these views, the extravagant or careless statements, I regret to say, of our own profession are largely to blame.

When a physician asserts that consumption is "as contagious as small-pox" and that "hospitals for consumptives are a source of danger to the whole surrounding community," I consider him culpable for making perfectly unwarrantable statements that can not be borne out by facts.

It has been proved by observation in the communities near two of the largest sanatoria for consumptives in the world—namely, Goerbersdorf in Silesia and Falkenstein near Frankfort, that consumption has lessened in amount among the entire population since the introduction of the sanatoria there, largely due, it can justly be said, to the strict hygienic rules which are used at the sanatoria for the disposition of sputa, and which are taught to the inhabitants in the surrounding villages.

It is doubtless perfectly true, on the other hand, that in various "open resorts" for consumptives where strict methods for disinfection of the hotels and boarding houses are not enforced, the death-rate among the natives from consumption has increased greatly, the most striking cases being those of Mentone and Nice, where, according to statistics, consumption has greatly increased since the place has become such a common resort for phthisical patients, many of whom through carelessness or ignorance become sources of contagion to others.

Whether this increase of consumption among the natives is due to the lack of strict hygienic rules among the hotels and boarding houses for phthisical patients in Nice and Mentone, or because the native population have changed their former out-of-door occupations to the more confined life of hotel attendants, may be justly questioned, and yet the difference between the experiences at Mentone and at the two great sanatoria just mentioned is very striking.

In a very interesting paper entitled *A Study of the Infectiousness of the Dust in the Adirondack Cottage Sanitarium* (*Medical Record*, December 28, 1895), Dr. Irwin W. Hance has given some results which prove how little danger there is of infection in properly regulated institutions.

Guinea-pigs were inoculated with the dust taken from various rooms of the sanitarium, and tuberculosis was found to be present only in the animals who had been inoculated with the dust from the room of a careless patient who had been complained of for spitting on the floor, a striking example of the absolute necessity of cleanliness in this particular.

In the large hospital for consumptives at Brompton, London, where the same strict hygienic rules are maintained as at the great sanatoria of Germany, the percentage of hospital attendants who have developed phthisis is very small indeed, according to the statements of Dr. C. T. Williams.

Directly bearing upon the subject in question are the scientific and very important experiments of Dele-

pine and Ransome with reference to the germicidal effect of various substances upon the bacilli of tuberculosis. In these experiments exposure to the full rays of the sun for a comparatively short time (a few hours) proved the most efficient germicide of all, it being sufficient to render the bacilli completely inert, the inoculated animals showing no signs of tuberculosis. The experiments were made, it is important to state, with dried sputa, and not with simple cultures of the bacillus.

They found, moreover, that the 1-to-10 or 1-to-100 solution of chlorinated lime proved to be the most efficient method of disinfecting the clothing, the walls, and the floors upon which the sputa had been expectorated.

A. K. Stone and others have proved the extreme vitality of the bacilli when not exposed to the sun—sputa dried for three years in a dark place having produced tuberculosis in animals; but we need the results of more extensive experiments in the direction Ransome has taken, the importance of which in the practical everyday dealing with consumptive patients can hardly be overestimated.

As a result of the experiments of Ransome, it is certainly a legitimate doubt to come to our minds as to how far we need fear infection from sputa which are expectorated on to the open ground exposed to the full rays of sunlight. Not that I would relax one iota in the restriction of the disgusting habit (to say the least) of spitting publicly anywhere; it is only a question as to its danger under the condition of exposure to the sun's rays.

Thus we have scientific facts to help us in trying to show the laity that the consumptive need not be treated like a leper, or as one affected with the plague, but that moderate measures will prevent his being a source of danger to those about him.

It is doubtless natural that the ordinary hotel-keeper should prefer not to receive a guest far advanced in consumption for reasons other than fear of infection; but I have seen too much of the sadness arising from the fairly brutal disregard of the poor sufferer's feelings in some cases not to make me wish to beg for moderation in our statements to the laity lest we be guilty, not only of making assertions not based on scientific truth, but also of adding unnecessarily to the mental suffering of those who are already overburdened with physical ills.

In conclusion, let me emphasize my own position in this matter, lest by any chance I should be misunderstood as wishing to relax in methods for perfect cleanliness about the consumptive patient. I advocate most firmly the destruction of the sputa by fire or other methods of disinfection. I believe also that the rooms occupied by a consumptive patient should be thoroughly cleansed with chlorinated lime or carbolic acid; in short, that all reasonable methods should be adopted to kill the germs of the disease; but I wish to refute the statements that *properly regulated* consumptive hospitals are sources of danger to the community when I believe them to be exactly the opposite, as shown by statistics. I wish also to plead for the consumptive who in his exile is made to feel the forlornness of his condition still more keenly by the selfishness of those who, in their desire to escape the possibility of infection, shut their doors in his face, as it were, utterly regardless of the mental suffering they are inflicting.

Future experimentation will doubtless throw more light upon the subject; but meanwhile let us in our zeal as physicians be careful not to make statements which we may be obliged later to retract as not being founded upon scientific truths.

## Lectures and Addresses.

### A CLINICAL LECTURE\*

#### ON A CASE OPERATED UPON FOR THE RADICAL CURE OF INGUINAL HERNIA AND FOR URETHRO-RECTAL FISTULA.

By GEORGE WOOLSEY, M. D.,

SURGEON TO BELLEVUE HOSPITAL;  
PROFESSOR OF ANATOMY AND CLINICAL SURGERY  
IN THE MEDICAL DEPARTMENT OF THE NEW YORK UNIVERSITY.

GENTLEMEN: The case for operation to-day is one of urethro-rectal fistula connecting the prostatic urethra with the rectum and associated with strictures of the urethra. In addition the patient has a left oblique inguinal hernia.

The patient is a man, thirty-four years of age, who had a first and severe attack of gonorrhœa seven years ago. This was neglected and had lasted some months when he used a strong injection of zinc sulphate, after which the discharge diminished; but he suffered from chordee, the stream became smaller, and there was an occasional gleet discharge. Three years ago a second attack of gonorrhœa, followed by right epididymitis, left him with a still smaller stream, to pass which he had to strain. About a year ago it became necessary to sit down and strain as at stool in order to urinate, and by straining he brought on a left inguinal hernia. At this time, after suffering severe pain in the region of the prostate for a time, he noticed that on straining a few drops only came from the penis, but a large amount from the anus. This condition has persisted until now. Most of the urine is passed from the anus on straining; there is no leakage at other times. He has lost some flesh during the past year, but he has no organic disease.

From the history we can safely make the following diagnosis of the course of the case: Cicatricial urethral stricture of gonorrhœal origin; abscess of the prostate opening into both rectum and urethra and resulting in a urethro-rectal fistula; left inguinal hernia. Notice that nothing is said of fecal mater passing through the urethra. This is the usual condition, owing partly to the oblique direction of the fistula from above and in front downward and backward, and partly to the small size of the fistulous tract.

Such a diagnosis is confirmed by the examination, which revealed a stricture of the deep urethra through which, after the passage of a filiform bougie, a tunneled catheter, No. 6, French scale, could be passed. Through the rectum, the prostate felt hard and enlarged, and in a median depression there was felt a small button of granulations indicating the rectal opening of the fistula.

Such a fistula is not very common. It may result from the breaking down or ulceration of carcinomatous

or tubercular processes in the prostate, but more often it is the result of a prostatic abscess which ruptures into the rectum as well as into the urethra. Under the latter conditions a permanent fistula does not necessarily or usually result. The urethral stricture is largely accountable for the permanence of the fistula in this and other cases by making the passage of urine by the normal route difficult, and by the frequent passage of urine through the fistula preventing its closure.

Such fistulæ have often given much trouble to cure, and many have resisted all attempts at closure. Operations on the plan of Sir Astley-Cooper's have been the most successful. In this operation, through the incision for external urethrotomy and perineal drainage of the bladder, the fistula is divided transversely to its direction between the rectum and the prostatic urethra, and the two halves are curetted. Into the rectal half a little gauze is packed from the perineal incision, without passing through into the rectum, and the prostatic half is opened up into the perineal wound. The gauze packing and the large perineal drainage-tube prevent the urine from passing into the rectum, thus allowing the rectal half to heal while the prostatic half heals with the rest of the perineal incision after the withdrawal of the tube.

The division of the fistula and the longitudinal or lateral displacement of the two halves, so that they no longer correspond or form a continuous tract, are rendered impracticable by the firm connections between the rectum and the prostate and trigone of the bladder. If a procedure such as I have described should fail, a freer exposure of the parts would be indicated. This could be obtained by a transverse incision in front of the anus and slightly concave dorsally or, still better in such a case, by a short median perineal incision curving around to the left of the rectum and then passing backward a variable distance in the median line, an incision which I have employed in one case of "lateral prostatectomy" by von Dittel's method. By such incisions and exposure of the parts between the rectum and the prostate we could divide the fistula, freshen the edges, and suture the rectal part. The rectal portion is the key to the situation, and, if healed, assures success in nearly every case not due to a malignant or a tubercular process.

In this case we operate first for the radical cure of the inguinal hernia, as it is more feasible and more important to have this part of the operation aseptic. The method we employ is a combination of Bassini's and Halsted's. First find the external abdominal ring, by slightly invaginating the scrotum; then incise down to the aponeurosis of the external oblique muscle, for the distance of four inches or more, from a point over the course of the cord one inch below and internal to the external ring upward and outward a little more vertically than the canal and to a point an inch or two beyond the internal ring.

In this incision several veins of some size are usually

\* Delivered in Bellevue Hospital to the students of the University Medical College.

met with, as you see here, and are clamped before or after division. I call your attention to the fact that these vessels rarely require ligature. In fact, in these hernia operations we hardly ever use a ligature on a vessel, but before we are ready to open the sac we clear the field of clamps after first twisting the vessels. In this or any operation where we suture the wound completely the fewer the ligatures the fewer are the possible sources of infection.

The external oblique aponeurosis and the external ring are easily seen and felt, as you see, when we reach them. Introducing the left forefinger well up into the canal in front of its contents, we slit up the canal and search for the sac, expecting to find it in front of the cord. It is often more easily found here in the canal than below the external ring. When it is found it is opened and the opening marked by a clamp.

Starting from the margin of the opening, it is much easier to secure the sac proper and then separate it from its surrounding parts than if we tried to isolate the sac before opening it. For if we try to isolate the sac plus some outside layers, it is much more difficult than if we have the sac alone. Occasionally there is considerable difficulty in separating the sac from the cord and its vessels, but not often if we have the sac alone and nothing else with it. If the cord and its vessels are too roughly handled there is danger of setting up an epididymitis, which we may treat by the local use of guaiacol, the cautery, and dry poultices.

If the canal has not been already slit up to its full extent it is slit up now into and beyond the internal ring, and the weaker and less muscular the abdominal wall the farther beyond the ring is the incision carried. We can now isolate the neck of the sac until it begins to spread out funnel-like above, indicating that we have reached the point where it is continuous with the parietal peritonæum. At the latter point, the sac being empty and pulled out tightly, a ligature loop is passed through and tied around it in a Staffordshire knot. During this act the forefinger in the sac prevents the inclusion of the contents in the ligature. The ligature saves time as compared with a regular suture of the peritonæum, which we sometimes practise, according to Halsted's method, if for any reason the neck of the sac has been split or torn up. In freeing the inner side of the neck of the sac we almost always meet with a layer of fat adherent to the peritonæum of the sac and to the parietal peritonæum. If this fat is excessive we may remove much of it, but if we attempt to remove it all it is very easy to tear through the neck of the sac, and it does no harm to include some of the fat in the ligature.

In isolating the neck of the sac, and especially in removing any excessive fat to its inner side, we should bear in mind the possibility of a hernia of the bladder, which, if not recognized, may lead to serious if not fatal consequences from a wound of that viscus. In a recent case of this kind, of the commoner or extraperitoneal variety, I

fortunately recognized the condition, and was able to reduce the herniated part of the bladder and proceed as usual. Remember that the part of the bladder protruded in such cases bears little if any resemblance to the normal bladder, but is likely to be very much thinned.

For the ligature we use stout catgut, chromicized catgut, or kangaroo tendon, according as the circumstances of the case demand a ligature that will remain unabsorbed a shorter or a longer time. In cases of not too old or too large hernias stout catgut is sufficient in my experience. Let me caution you against using non-absorbable materials for ligatures or buried sutures in hernia operations; for they are very apt to give trouble sooner or later, even after remaining quiet as long as two or three years, though more commonly earlier.

In ligating the neck of the sac we do it as high as possible by making traction on it when the ligature loop is passed through, so that when the traction is let up the inner surface of the parietal peritonæum spreads out smoothly. The same object may be obtained by twisting the neck of the sac and then tying it off, as recommended by Bassini. But it is quite possible that a simple circular ligature may slip off, as I found that it did in one case where, after operating on a hernia, I opened the abdomen for a septic peritonitis due to an injury and not accounted for by the contents of the hernia. The ligature was found to have slipped off, probably in a mild fit of coughing before the laparotomy. Since then I have always passed the ligature through as well as around the neck of the sac to prevent its slipping.

We now cut away the sac to within half an inch of the ligature and see that the cord is well freed up to the internal ring, as it is to be brought out at the external angle of the incision.

I have not often found it necessary to reduce the size of the cord by removing some of the veins, as Halsted has proposed. In the very few cases where I have tried it I have found some difficulty from hæmorrhage or the large number of ligatures required, unless I removed all the veins contained from the pampiniform plexus, for the plexiform arrangement often, or usually, continues up into the canal, making a partial removal difficult. In two recent cases I have found a large amount of fat in and about the cord. This fat I have removed, for if, being left, it should atrophy, it would leave the opening through which the cord passes unnecessarily if not dangerously large.

We now proceed to sew up the canal, beginning just internal to the cord and often placing one suture external to the cord. We include in the suture not only the cut walls of the canal, but pick up with the forceps its dorsal wall, formed by the transversalis fascia and (internally) by the conjoined tendon, and include them in the suture. If we did not pick them up with the forceps we might in passing the needle through them also include or puncture the deep epigastric vessels, or even

wound the external iliac vessels. After passing the necessary number of sutures to close the canal and the external ring, we tie them and find, by examining with the finger, that the canal and external ring are entirely obliterated.

The cord, after it emerges from the abdominal wall, is made to pass between the skin and the external oblique aponeurosis, after Halsted's method, instead of under the aponeurosis according to Bassini's. The latter's method requires an additional layer of sutures, and the cord is in a position where it is more shut in, so that it can not escape from the pressure of a truss, if one is required, and is in danger of being compressed by cicatricial contraction. To avoid its being imbedded in the main scar, and in order to strengthen the latter, I have for some years employed from three to five figure-of-eight or X sutures of silkworm gut through the edges of the skin and those of the aponeurosis, brought together by the deep suture. These sutures were recommended by Dr. Fowler, of Brooklyn, and I think they are of service. When tied, they bring the skin close down to the line of the deep suture, and the cord lies above them, where there is more room than below, between the incision and Poupart's ligament. The ends of the incision are now sewed up by a continuous suture of silk or cat-gut, without drainage, and a proper dressing is applied.

The patient should be kept in bed for four weeks, and for six weeks should do no hard work. Although these wounds uniformly heal by primary union and the patients are thus well, so far as the wound is concerned, in ten days, I do not agree with Kocher in letting them up and out then, so that if poor they need lose little time from work, for the scar is not firm enough at this time to insure safety against recurrence.

As to the results of the operation, there is hardly any mortality in proper cases and in proper hands. The functional results, also, are so excellent that I am not in active search of another method of my own or another's devising, though the number published from time to time would seem to indicate that all do not get such satisfactory results. In view of the low mortality (or the lack of it) and the excellent functional results, we can safely recommend this operation not only to those doing manual labor, in whom a truss is ineffective or painful, but to all hernia patients with whom a truss is either ineffective, irksome, or unpleasant.

We now proceed to operate on the urethro-rectal fistula on the lines of Sir Astley Cooper's operation as described above.

Besides the strictures of the urethra, which we divide by a combined external and internal urethrotomy, we find somewhat of a transverse ridge on the floor of the outlet of the bladder, which in my experience is not an uncommon condition and accounts for many obstinate genito-urinary conditions. This ridge is incised mesially and the vesical outlet fully dilated by the finger. With the aid of a speculum in the rectum we can see what we

described as having felt—namely, two lateral projections of the prostate and a button of granulations in the median depression between them. A bent probe passes in here and touches a large sound in the urethra, and can also be felt on the floor of the prostatic urethra by the finger introduced into that portion. Guided by the finger and the probe, the fistula and the tissues for a little distance around it are completely divided at right angles to the probe.

We now thoroughly scrape with a small, sharp spoon the two halves of the fistula, and pack the rectal half at its prostatic end with a very little iodoform gauze, introduced through the perineal incision. A large rubber perineal tube is now introduced and the bladder is washed out with warm boric-acid solution.

We will leave this tube in for some time, at least two weeks or even more, and remove the packing in five days or a week, and shall then expect to find that the rectal opening has closed. The urethra easily admits a No. 31 sound, French scale, and will no longer be a factor in the case.

NOTE.—The perineal tube was left in nearly three weeks. Nothing marred the closure of the fistula except that, about four or five weeks after the operation, what was described by the nurse and patient as fecal matter passed from the penis on one occasion. This was not seen by the house staff or myself, the occurrence was not repeated, and the patient made a perfect recovery. He now passes urine only through the penis and in a perfect stream.

117 EAST THIRTY-SIXTH STREET.

### A STUDY OF SOME INFANT FOODS IN COMPARISON WITH MOTHERS' MILK.

By R. H. CHITTENDEN, Ph. D.,

PROFESSOR OF PHYSIOLOGICAL CHEMISTRY IN YALE UNIVERSITY.

THE tendency in infant feeding at the present time is clearly toward as close an approximation as possible to woman's milk—to the scientific rather than the empirical method. In view of this fact, it has seemed to the writer a matter of importance to ascertain how near some of the more widely used infant foods approach to this now theoretically accepted standard.

Owing to the varied nature of the so-called "infant" foods—to the lack of any recognized standard of composition for the various sorts of foods, farinaceous, malted, Liebig, etc.—it becomes evident that the most practical and most satisfactory method of comparing an infant food with mothers' milk is to analyze the food as it is prepared for the nursing bottle. Due weight must necessarily be given to the directions for preparing the food for use; for these are plainly of primary importance in determining the real food character and value of the product. It is the food in the nursing bottle that is fed to the infant, and it is the composition of this

product that we need knowledge of. Some of the directions, however, are so vague and offer such a wide variation in the proportion of the several ingredients that it would seem as if they were purely empirical and designed simply to give some food which would in some way agree with the child.

It should be pointed out, however, that many of these foods do not specifically purport to resemble mothers' milk. The general tenor of their makers' statements is that they add something to enrich or improve cows' milk for the nutrition of an infant; for instance, that cows' milk is, by the process of manufacture, by the drying with farinaceous and saccharine matters, made more digestible and wholesome for the infant, or that the addition of malted grains renders the milk more suitable, or better adapted for an infant's food. Moreover, the physical properties and characteristics of most of these foods are such that it would be difficult to suppose it was ever intended that they should resemble mothers' milk. It is, however, contended for nearly all these foods that the casein is in some way rendered digestible, so that it will curdle like mothers' milk, etc.

In preparing these foods for analysis, the directions given by the manufacturer have been followed as closely as possible, and where, as in the case of some of the foods, different proportions are recommended for different ages, the food has been prepared as directed for infants of six months, this being deemed the best course to pursue for comparative study; thus placing all on a fair basis, each to the other, as to the relative composition of the foods as actually in use at six to twelve months.

The analyses, therefore, present the composition of the several foods when ready for the nursing bottle, with water, milk, and cream added as specified in the directions. The accompanying table gives the results obtained, expressed in parts per hundred.

In the following discussion of these foods, it is the food as prepared for the nursing bottle that is to be understood as referred to.

A careful study of these results reveals many inter-

esting facts. Thus, only two of the foods show a specific gravity at all analogous to that which is usually taken as the average for mothers' milk; and these two foods contain an amount of solid matter not far removed from that of mothers' milk. The others have a comparatively low density in harmony with their smaller proportion of solid matter, two, as the table shows, having but about fifty-four per cent. and one sixty-three per cent. of the solid matter present in mothers' milk. Hence, whatever the character of this solid matter, these three foods are far weaker fluids than ordinary breast milk.

The very great difference in the physical properties of these foods should be mentioned, especially in view of the fact that some of the foods when warm are comparatively fluid and become quite thick or gelatinous upon cooling.

Just here, it is well to remember that the solubility of the constituents of milk does not depend upon temperature. Lactose, mineral salts, and maltose are readily soluble in cold milk as well as in cold water; so that cows' milk, or a properly modified milk, is not noticeably thinner when warm than when cold. When, however, fresh milk has been evaporated to dryness, the solid matter so obtained is not soluble or readily diffusible in water, owing to the incorporation of hard casein and fat. In Nestlé's milk food, for instance, there is a very rapid separation of the milk mixture into two distinct layers—viz., an upper thin layer, and a heavier layer containing considerable insoluble albuminoid and starch.

The thickness of a food such as Nestlé's and imperial granum particularly is undoubtedly due to the presence of starch, which thus shows its characteristic behavior upon mixing with water and boiling.

With regard to the amount of mineral matter, two contain approximately the same percentage as mothers' milk, while the others have either an excess or deficiency of these important elements, the excess being in all cases due chiefly to alkaline carbonates. Although the proportion of inorganic salts present in milk is small, the

† By direct estimation.

importance of mineral matters in the nutrition of the infant is not to be ignored or lightly passed over. The growing infant must have a bony framework to support its rapidly developing tissue, and if the necessary elements are not contained in its daily food, how are they obtained?

The albuminoids which are so essential for the growth and well-being of the animal organism, whether young or old, are seen to vary in these foods from 0.81 to 2.62 per cent. Compared with mothers' milk, all but two show wide variations. Imperial granum and milk modified by peptogenic milk powder, however, contain practically the same amount of albuminoids as average breast milk. Mellin's food, on the other hand, contains thirty-one per cent. more albuminoids than mothers' milk itself; malted milk has fifty-seven per cent. and Nestlé's food forty per cent. of the albuminoids present in mothers' milk.

It is to be noted, further, that differences exist in the character of the albuminoids present, as indicated by the fact that in some of the foods a certain proportion of the albuminoids is in an insoluble form. Thus, in imperial granum, more than one fourth of the total albuminoids are insoluble. In Nestlé's food more than one half of the albuminoids are in an insoluble form.

There are still other differences, not shown in the analyses, that need to be considered in connection with the albuminoidal matter of these foods. Thus it is a well-known fact that the albuminoids of human milk differ in a number of ways from the corresponding bodies in cows' milk. Leaving differences in chemical composition, etc., out of consideration, we may merely call attention to the way in which casein behaves when fresh cows' milk is mixed with dilute acid, as the hydrochloric acid of the gastric juice. Woman's milk, when mixed with dilute acid, such as one-per-cent. acetic acid, or 0.2-per-cent. hydrochloric acid, yields a soft, flocculent precipitate of albuminoid, which is very different from the tough and solid curd formed in cows' milk. The difference is not due merely to difference in the proportion of albuminoid contained in the two milks, but rather to the nature of the substance itself. Simple dilution of cows' milk with water is without avail in obviating this tendency of the milk to form tough and more or less indigestible curds. It is obvious, therefore, that any method of modifying cows' milk that aims to produce a product analogous to mothers' milk must take into account this radical difference in the nature of the two caseins.

The very first step in the process of digestion is the precipitation of the casein in the stomach by the combined action of the acid of the gastric juice and the rennet ferment, and with a weak stomach the form in which the casein is precipitated is a mater of some moment. As to how far this difference has been taken into account in the preparation of the foods under consideration, we

can in a measure judge from the behavior of the several foods toward dilute acid.

This may be readily ascertained by placing a given amount, say five cubic centimetres of 0.2-per-cent. hydrochloric acid, on a watch glass, and then allowing the food to fall, drop by drop, upon the acid.

A simple and suggestive method is also to take some bulk, say two ounces of the warm food, in a glass and add the acid little by little, stirring gently. Tested by these methods, it will be found that malted milk and Nestlé's food both yield a fine, flocculent precipitate on the addition of acid. Of malted milk it is stated that the casein of the milk of this food is altered by the action of plant pepsin, as a part of the process of manufacture. The incorporation of fresh, unaltered cows' milk with saccharine and farinaceous matters, and concentration and reduction to a dry pulverulent form, must result in a food containing casein in fine, hard, granular particles, and this may account for the fact that a dried milk food like Nestlé's, when diluted and prepared with water, does not behave at all like fresh milk casein to dilute acid.

We have a striking illustration of this in the behavior of Mellin's food with the acid. Here the casein separates in flocks or curds when the dilute acid is added to the prepared food, thus showing that the addition of soluble maltose and dextrin to fresh milk does not of itself noticeably modify the character of the casein.

In milk modified by the imperial granum, the addition of acid causes a very thick separation of the casein, and the separated casein appears gelatinous rather than curdy, due probably to its intimate mixture with the starch paste of the imperial granum. The lack of the true casein curd common to cows' milk upon the addition of acid is not due in this case to solubility of the casein. It is the result evidently of mechanical mixture of farinaceous matter with the casein, by which the precipitated proteid is kept more finely divided. Further, it must not be overlooked that this result is accomplished by the addition of a substance wholly foreign to the natural food of an infant, and it may well be questioned whether such a mixture is well adapted to its normal digestive functions.

In milk modified by the peptogenic powder, the specific statement is made that the albuminoids of the milk are truly modified by the process to which they are exposed when the diluted milk and cream are warmed with a specified amount of the powder. In conformity with this statement it is found that the precipitate produced by acid, while naturally bulky from the due amount of albuminoids present, is composed of soft, non-adherent coagula. It is further evident, from the bulk of this precipitate, that the proteolytic action made use of in the preparation of the milk for the bottle has by no means resulted in the complete digestion of the proteids of the milk, the transformation resulting simply in a modification of the casein, with solution of a

small amount of proteid, so that the precipitate produced by acid is much less bulky and less coherent than that from similarly diluted cows' milk, to which has been merely added maltose or lactose. So far as our results show, cows' milk, modified by peptogenic milk powder, is not to be classed with predigested foods, for the reason that the proteids of the milk are so altered as to render them closely analogous to the proteids of mothers' milk without converting them wholly into soluble albumoses and peptone.

These observations naturally raise the question of whether any of these foods, when made ready for the nursing bottle, contain active forms of enzymes of any sort, particularly proteolytic or amylolytic. So far as we can find, the answer to this question is entirely in the negative. None of these foods when prepared for use contain any active enzyme capable of converting either starch or proteid.

The enzyme of the peptogenic milk powder is obviously destroyed in the boiling to which the fluid is subjected during the preparation of the food. Hence the conclusion that all of these foods when prepared for the nursing bottle are to be judged solely on the basis of their food value, since none of them possess any recognizable digestive power.

Neither is any one particularly or unduly digestible as compared with mothers' milk. Their utilization by the system depends wholly upon the digestive power of the infant's own secretions.

With reference to the quantity of fat contained in the several foods when prepared for use, only one contains any approach whatever to the amount characteristic of mothers' milk. In the food prepared by the peptogenic milk powder the natural deficiency of fat which results from the dilution of cows' milk has been overcome by the addition of a certain amount of cream, an addition which, as the analyses show, is fully competent to attain the end in view. In all the other foods the deficiency of fat is marked, as the table of analyses shows. The necessity and importance of adding cream or fat to fresh cows' milk, in order to bring the proportion of fat up to that of mothers' milk, is here well illustrated, while the deficiency of fat in the foods prepared with the dried milk products is extreme—very far below that of mothers' milk.

The carbohydrate material of mothers' milk, as well as of cows' milk, is composed solely of milk sugar. In human milk the average amount, according to Leeds, is 6.93, while in cows' milk the percentage of the sugar is nearer 4.5. In malted milk and in Mellin's food the total carbohydrate matter, represented by milk sugar, maltose, and dextrin, is not widely divergent from that of breast milk. It is to be remembered, however, that maltose and dextrin are foreign substances, not contained either in cows' milk or human milk, and, while both are undoubtedly possessed of high food value, yet it is equally evident that Nature gives preference to milk

sugar or lactose as the proper form of carbohydrates for the nutrition of an infant.

As soon as the growing infant acquires the ability to subsist upon solid foods the farinaceous matters naturally consumed are converted into dextrins and maltose by the enzymes of the several digestive juices. But, prior to this period, the food provided by Nature for the sustenance of the young is characterized by the complete absence of every form of carbohydrate matter except milk sugar. It may be said that infants thrive as well upon maltose or sucrose as lactose, but in the writer's judgment there is no good ground for such an assertion. It may be true, but positive proof is wanting. However, at the present time, the writer's purpose is to simply call attention to certain facts bearing upon the chemical composition of infant foods in their relation to mothers' milk; and, limiting ourselves to this point, we see on reference to the table, that only one product compares with breast milk in the kind and proportion of sugar present. All the others contain more or less milk sugar; but in addition to this carbohydrate they are characterized by the presence of variable amounts of maltose, dextrin, cane sugar, soluble starch, or starch, all of which are foreign to natural milk.

The writer would not be understood as speaking in a derogatory way of any of these food products, or as eulogizing one product at the expense of another. They are all, no doubt, of value and useful, but with one exception, when prepared for use, they show wide variation from the composition of human breast milk. It may, perhaps, be a matter of opinion as to what constitutes the best diet for a young infant; but if we are to adopt mothers' milk as the standard, then it is well for us to consider how far and in what respect the infant foods widely used differ from this standard.

Cows' milk is without question the best material available for the nutrition of the infant when the latter is deprived of its natural food, and any modification that will render this fluid more closely analogous to breast milk is certainly to be recommended on physiological grounds. That there is no special difficulty in modifying cows' milk so that it will resemble mothers' milk, both qualitatively and quantitatively, is clearly apparent from the analytical results shown in the table. Cows' milk, modified by the addition of water, cream, and peptogenic milk powder, offers a product containing to the full extent all of the proximate principles present in human breast milk and wholly free from extraneous admixtures. The proportion of solid matter, fat, albuminoids, carbohydrate, and inorganic salts corresponds as closely as one could ask with what is considered as the average chemical composition of mothers' milk, and in this respect the product differs notably from all of the other products examined. Further, the process of modification takes into account the radical difference between cows' casein and human casein, and affords a method by which the former can be modified

to a closer resemblance to the latter without the addition of any substance that will permanently interfere with the purity of the final product.

The general resemblance of milk modified by the peptogenic milk powder to the infant's natural supply is a very striking one. The logical outcome of the present scientific attitudes must ultimately place infant feeding on a practical, exact basis which will supersede the empiricism which has too long prevailed. In the consistent pursuit of this scientific attitude lies the only hope of any real progress.

### EXPERIENCE WITH PILOCARPINE IN THE TREATMENT OF THE URÆMIA OF BRIGHT'S DISEASE.\*

By CHARLES J. PROBEN, M. D.

THE introduction of the active principle of jaborandi leaves by Gubler, lauded for its remarkable physiological effects, and its recommendation for a vast number of diseases, has suggested no greater field of usefulness than in the treatment of anasarca, albuminuria, eclampsia, and uræmia resulting from nephritic disorders. Whatever speculation the theory of uræmia may invite, whether solely due to the retention of urea or other nitrogenous excrementitious substances in the blood, or whether due to other acquired vitiated blood changes, with or without vasomotor disturbances, the most practical inference of relief would appear to be a diversion of this poison to some organ which is capable of temporary augmented elimination. We are cognizant of the fact that these toxic elements produce a most profound impression upon the circulatory apparatus, the nerve centres, and the viscera, and that relief is urgently demanded, especially if coma or eclampsia supervenes.

If strict dietetic regimen, hydrotherapeutics, diuretics, and cathartics prove of no avail, the office of the skin as an eliminator should finally be called into account. A decidedly rapid and energetic impression on the sweat glands is indicated, and what drug at our disposal would seem to meet this demand more vigorously than pilocarpine, the active principle of jaborandi leaves? True, these leaves contain other alkaloids, and an amorphous substance called jaborine, which is akin in its physiological action to atropine and a direct antagonist of pilocarpine; hence none but the crystalline salts of pilocarpine should be prescribed. Two other alkaloids; pilocarpidine and jaboridine, are described by Merck, the former simulating pilocarpine and the latter jaborine, but these are of no interest to us here. Let us rather briefly consider the physiological action of pilocarpine. An infusion of jaborandi leaves requires ten minutes for its physiological action, while a hypodermic injection

of a pilocarpine salt, which is far more trustworthy, requires but from three to five minutes.

The phenomena observed from a full dose in an adult are markedly increased secretions emanating from the skin and the salivary apparatus. Incidentally it acts slightly on the genito-urinary organs, exerting a contractile spasmodic influence on the bladder wall, producing, at times, pain over the pubic region with an irresistible desire to urinate. On the renal organs its action is practically nil, though Tyson attributes to it a slight diuretic action; granting such an action to occur, no beneficial results can be thus attributed to it in Bright's disease.

On the eye, pilocarpine acts as a meiotic, producing slight impairment of vision; its local use finds but a meagre place in ophthalmic practice. As a galactagogue Cheron and Ringer have recommended it in one-twelfth-grain doses. A minor action is manifested on the nasal, lacrymal, and intestinal mucous membrane. A unique effect, and one worthy of more attention than has been bestowed upon it, is its stimulating nutritive effect on the hair, causing it to grow, and to become coarse and darker in color. Andre and Prentiss have demonstrated its practical utility in alopecia by recording and exhibiting some rather remarkable results. The sialagogue effect of pilocarpine is manifested somewhat earlier than the sudorific. The saliva, which at first is thin and aqueous, soon becomes viscid and ropy, and is secreted so rapidly and in such quantity that there is a continual flow from the mouth, so that the person is unable to speak, and has been known to have nearly become suffocated. A similar secretory activity may overcome the tracheal and bronchial mucous membrane, pouring mucus abundantly into the tubes, thus materially impeding respiration. The sialagogue effect may persist for two hours and bear a distinct relationship to the sudorific activity. As a rule, both secretions are very much increased, but one function may be much more active, thus diminishing or partially replacing the other. German authorities estimate the saliva secreted to be from two hundred and fifty to seven hundred and fifty grammes. Americans think it nearer five hundred to a thousand, which must be regarded as an enormous quantity. The secretion is due to a direct stimulation of the submaxillary, sublingual, parotid, and buccal glands, as the action continues after section of the nerves. This peripheral effect suggests its local application to the parched condition of the buccal mucous membrane and tongue in diabetes, and practical experience bears out its utility. No urea is said to be secreted by the saliva (Schwann, Craig, Peliere). After a primary flushing of the face the sudorific effects become visible on the exposed parts, extending rapidly over the whole surface. Half an hour shows the height of this process. The transudation of fluid becomes very profuse, and is visible as little beads exuding from the mouths of the glands, which coalesce, and the quantity becomes so enormous that the sweat

\* Read before the New York County Medical Association, May 18, 1896.

rolls from the body, thoroughly wetting the bedclothes. It has been estimated that thus an adult secretes five hundred to a thousand cubic centimetres of fluid. Brunton thinks the latter figure nearer the truth, while some have assumed that as much as three thousand cubic centimetres is a possibility (Prentiss). This latter amount seems rather exaggerated, even in spite of intrinsic causes which may notably influence the result. Given a person in bed, well covered, in a warm room, with ingestion of copious draughts of warm water in order to supply the loss by transpiration, the sweating stage may be continued for hours, thus materially increasing the quantity. The difficulty of estimating the amount only approximately accounts for the discrepancy existing among the various observers. After the flushing of the face, which is but short in duration, the sweating becomes active in half an hour and persists for four or five hours. During this time the skin is pallid, showing that the sudoresis is not due to a determination of blood to the surface, but rather to a direct action of the drug upon the sudoriparous glands, being a peripheral and not a central action, as the sweating continues despite the section of the nerves. Coincident with the onset of sweating there is a slight rise of the internal temperature, averaging half a degree to one degree Fahrenheit. This is, however, not so constant as the fall, which is secondary, and persists for a day or two. The reduction depends upon the heat loss due to the profuse transpiration and the subsequent vascular depression.

The quantity of solids secreted is still a matter of speculation; it is assumed that about a gramme is abstracted by a "sweat," which is quintuple that normally lost. In uræmia we would naturally expect a large quantity of urinary constituents to be excreted, but in the absence of experimental proof the quantity can only be surmised, Bartholow thinking it to be enormous.

The effects of pilocarpine on the circulatory apparatus are striking and of great practical importance. That it has any but a salutary effect is recognized by the increased frequency of the cardiac beats, the pulsations increasing often forty to fifty a minute, with a decided lowering of the vascular pressure demonstrated by the diminished tension of the arteries. A primary slowing of the pulse, with increased arterial tension, may be recorded, which is, however, evanescent. The undesirable effects of pilocarpine on the circulation are attributed to a relaxation of the arterioles caused by the vasomotor paralysis, and a direct depressing effect on the cardiac muscle, diminishing its energy and increasing the number of cardiac beats. This depression of the heart is very much akin to that caused by nicotine. The toxic effects of pilocarpine are neutralized by atropine; the cardiac beats may be brought back almost to the norm; its action of antagonizing the secretory effects is also quite marked. In three men the perspiration caused by an infusion of *jaborandi* (one drachm each) was distinctly arrested by one one-hundredth of a grain of atropine.

In a case on record the toxic effects of nine tenths of a grain of atropine were neutralized by the hypodermic use of pilocarpine; the enormous dose of nine grains was given in divided doses during two hours with final success. A similar case is recorded in which four grains and a half of pilocarpine were injected during a period of seven hours to neutralize a grain and a half of atropine, with an ultimately favorable result. The antagonism of these drugs, so well established, should call for its more general application in toxic cases, though atropine poisoning has been far less amenable to treatment than pilocarpine poisoning. Following the exhaustive sweats produced by pilocarpine a stage of marked depression appears, in which the vitality is lowered and debility persists for a number of days. The skin is pallid; there are languor, chilliness, frontal headache, dizziness, drowsiness, with disturbances of vision. These symptoms are due to the diminished quantity of fluid in the arterial system, with a lessened vascular tonus. Nausea, vomiting, and diarrhoea may be the onset of a severe and alarming condition. Collapse may confront us, with extreme weakness, contracted pupils, slow, sighing respiration, vertigo, and a feeble, rapid pulse, which is an alarming condition, and for which the appropriate remedy is atropine and the circulatory stimulants. So much for the effects of pilocarpine, and now let us tersely review some of the uses it has been put to.

Its prompt and vigorous action suggests a use in those disturbances of the economy in which the lessened secretion accounts for an accumulation of toxic elements in the blood, which imperatively call for rapid elimination by other channels. It is known that in sweating many diffusible salts are carried off, and that that unknown one or number on which uræmia depends is probably included. Especially is this the inference when the blood is surcharged with these toxic elements. Admitting that pilocarpine has proved itself very beneficial in some of these instances, its application would naturally not have to be restricted were it not for some of the untoward effects which may appear when they are least expected. Not being able to meet the underlying pathological cause, it must be designated a palliative remedial agent, and its use is naturally restricted, but is permissible if it can tide the afflicted over the critical period. Hence we see only temporary, meagre, and uncertain results can be expected from diaphoresis in chronic Bright's disease. In some of these cases inactivity of the skin is noted, especially if accompanied by dropsy, and the slow response to chemical sudorific agents should give the preference to the hot-air bath, hot pack, and similar procedures, which are not as embarrassing to the circulation as pilocarpine. The labor and inconvenience entailed in executing such troublesome measures outside of the hospital account for the preference given the more readily executed and relatively simpler method of hypodermic injection. In extremely urgent and dangerous cases the patient is generally too

exhausted to bear the depressing effects of pilocarpine without jeopardizing his chances of recovery. Even if kept under constant surveillance and as a *dernier resort* such a hazardous measure should, in general, be emphatically condemned.

Barker, Henoch, and Sanger have in good time sounded a word of warning and decried the use of pilocarpine in puerperal eclampsia and the uræmia of chronic Bright's disease. Barker has on record three fatal cases due to its use in puerperal eclampsia (uræmic); one died with an excessive transudation into the pulmonary cells, cerebral oedema, and cardiac paralysis; another with marked effusion into the pleural cavity, and a third with convulsions and symptoms of depression. Sanger reports three cases of puerperal eclampsia treated with pilocarpine; two patients died and one recovered, each experiencing suffocative symptoms from inability to swallow the saliva. Similar cases can be found scattered throughout the literature, but they are meagre compared with the number I expected to see. In view of these facts, are we justified in resorting to so dangerous a remedial agent as pilocarpine, even assuming that salutary effects are obtained, but not sufficient to overbalance those depressing and alarming ones on the circulation which may unexpectedly arise? There is still a division of opinion on this important subject, and I will cite the opinion of some of our authors. On the one hand, we have Wood and Osler, who laud this remedy: the former considers it the most efficient remedy for uræmia at our command, while Osler, after having abandoned its use, seeing several cases of collapse follow, has recently resumed it again with beneficial effects in doses of a sixth to an eighth of a grain. On the other hand, we have Loomis, Strumpell, Barker, Sanger, McLane, Murray, and others who more or less condemn its use. Loomis considers it a dangerous remedy, and says it may be used, but cautiously. Strumpell uses it only exceptionally, giving the preference to hot baths. The American translator, Shattuck, is inclined to use it in large doses in uræmic convulsions (a quarter of a grain), but admits that it sometimes acts as a decided cardiac depressant. These remarks apply solely to the treatment of uræmia and other allied affections of Bright's disease by pilocarpine. Barker has shown its danger, and states that the depressing effects produce wakefulness, an unwelcome condition antagonistic to the hypnotic influence on the nervous system which we desire to attain; from this fact alone he considers its use in eclampsia is contraindicated. In uræmia, after failure of repeated attempts to stimulate the various excretories and eliminate the noxious materials from the blood, very bright expectations are entertained from active stimulation of the secretory apparatus of the skin by pilocarpine. Assuming that one thousand grammes of fluid are thus abstracted, containing a half of one per cent. of urea, and this is a high allowance, the total quantity of urea secreted would barely be one seventh that voided diurnally by the normal kidneys; hence,

amelioration only, and not such brilliant results as depicted, can be expected. Besides, the depressing effects call for the greatest circumspection in its administration in the presence of any indication which may permit of its use. Probably the only justification for its use in uræmia is where there is a simple hypertrophy of the heart with a strong action, and here its effects are said to be immediate and striking. It is not so much the uræmia, eclampsia, or dropsy which confronts us, but the contractile power of the heart which forms the sole guide to the advisability of its administration. The paralyzing effects of pilocarpine on the arterioles and heart muscle prevent the proper propulsion of the blood, necessarily favoring stagnation, thus retarding rather than relieving the circulation.

This stagnation obtains in the pulmonic as well as the systemic circulation, and in the former produces rapid transudation with hyperæmia and resultant oedema of the lungs, a very frequent cause of death when pilocarpine acts unfavorably. Hence any dullness at the posterior portion of the lungs, especially at the base, from decubitus, with fine crepitating or mucous rales and an accentuated pulmonic second sound, forms a distinct contraindication to the use of this drug. General emphysema of the lungs, with a dilated right ventricle, which favors a stagnation in the pulmonary parenchyma, accompanied by impeded breathing and a tendency to cyanosis, also forms another decided contraindication. In pleurisy, with a marked effusion, displacing and consequently crippling the heart, it would be considered hazardous to administer pilocarpine. In coma, especially if intense, the reflex actions are inhibited, and those necessary for the swallowing of the saliva are checked, thus favoring the filling of the bronchial tubes with secretion, a condition which is apt to be followed by a fatal result. We have already seen that the condition of the heart muscle should form the sole guide to the advisability of administering pilocarpine, and the pulse being an indicator of that action may erroneously be used to interpret its intrinsic condition. To accurately ascertain the condition of the cardiac muscle, auscultation with the binaural stethoscope should be preferred. Progressive valvular lesions, especially if with disturbances of compensation; degenerations of the cardiac walls producing impairment of the muscular energy, with a diminished, indistinct, and impaired first sound, a feeble apex beat, and a frequent, irregular, intermittent, or dicrotic pulse form a class distinctly contraindicating the use of the drug. Fatty degeneration, dilatation, the so-called senile heart, and cardiac insufficiency, indicated by an indistinct, feeble, and diffuse apex beat, are included thus. Especially in the aged, in whom fibroid, fatty, and calcareous changes take place in the arteries as an atrophic and retrograde process of senile decay, and similar processes probably occur in the coronary arteries with degeneration of the cardiac muscular fibres, this rule particularly obtains.

To recapitulate briefly, we would say in general that any impairment of the first cardiac sound indicative of inefficient contractile power, with a weak apex beat, diminished arterial tension, and a feeble rapid pulse, would call for the exclusion of pilocarpine from our therapeutics. Hence a thorough examination of the heart is of paramount importance. As my discourse is specially directed to the contraindication for the administration of pilocarpine in the treatment of uræmia, I beg you will pardon me for transgressing the limits of this paper and indulging in a few remarks relative to the modern treatment of uræmia. Far more successful and striking than diaphoresis are the effects of directly attacking the blood and abstracting a certain quantity from the veins and replacing the amount by the introduction of a hot, sterile, saline solution. Beverley Robinson estimates that thus about ten times more urinary constituents are eliminated from the body than by diaphoresis. Such heroic measures have their limitations, but where the danger is imminent, the patient robust, with a high tension pulse, the abstraction of five hundred or six hundred, or even a thousand grammes, with the subsequent replacement of fluid, is followed by the most surprising results. The resulting emptiness of the vascular system may produce syncope, but in order to avoid this, a liberal quantity of hot saline solution (about one or two litres) is supplied, which dilutes the toxic elements and produces the most rapid and prompt diuresis known. It is my opinion that venesection is but rarely indicated, and the fluid to be supplied to the vessels may be taken up by the lymphatics from high rectal enema or cellular infusion. These are, however, subordinate to intravenous infusion, which is a prompt and decided diuretic, washing the urinary salts from the system quickly when a prompt action is required. An experience with two cases of uræmia, using intravenous infusion, leads me to corroborate the immediate effects and results obtained by Beverley Robinson and others. In conclusion, allow me to briefly outline a few histories recording some of the adverse results obtained from pilocarpine in the treatment of uræmia in my earlier experience:

CASE I.—C. A., a woman, aged forty-two years, presented herself to me with two large varicose, indolent ulcers of the legs of over five years' duration. Intermittently they would heal and reopen, so that I suggested Thiersch's skin-grafting. Nothing was detected in the general health or the urine to contraindicate the administration of an anæsthetic. Ether was given, the operation performed, and subsequent union proved satisfactory. The ether, however, produced a recrudescence of an old, undetected kidney lesion, which constantly diminished the quantity of urine, so that at the end of the third week the quantity voided was scarcely half a pint, in spite of diuretic and other treatment. Urine: specific gravity, 1.020; about one per cent. volume albumin; numerous granular and hyaline casts and epithelial cells; urea, five grains to the ounce. Heart and lungs appeared normal; no cerebral symptoms, except somnolence during day and delirium at night. Diagnosis:

Chronic uræmia with interstitial nephritis. The different forms of treatment that were instituted proved unsuccessful, the patient constantly getting worse; even the hot baths and air bath repeated daily failed to relieve, producing but slight sudoresis. At the beginning of the fifth week, as a *dernier resort*, I administered a third of a grain of pilocarpine hydrochloride hypodermically. Within ten minutes I was summoned to the bedside of the patient, who before appeared fairly rational and with a good pulse, and found her condition as follows: Collapse, semi-coma, rapid superficial respirations, accompanied by large rales heard at quite a distance, a feeble, flickering pulse, cyanosis of lips and finger tips, cold extremities, the surface covered by a cold, clammy perspiration, especially so over the face, etc. Auscultating the lungs showed them to be disseminated with large, moist rales, especially posteriorly, the heart sounds feeble, indistinct, and tumultuous. Diagnosis: Collapse from cardiac paralysis, with pulmonary oedema, due to the toxic effects of pilocarpine. Dry cupping, hypodermic injections of glonoin, digitalis, and strychnine proved of but temporary use and the patient succumbed within two hours. None but slight salivation and perspiration was noticed; apparently the pilocarpine had exerted its whole action on the cardiac muscle.

CASE II.—A woman, aged forty years, entered Charity Hospital with slight oedema of feet and eyelids; very anæmic, flabby; ocular disturbances and long-standing history of diminution in quantity of urine. Heart appeared normal, pulsations ninety per minute. Urine: quantity voided diurnally, thirty ounces; albumin, two per cent. by volume; granular casts; renal epithelium and diminished percentage of urea to the ounce. Diagnosis: Chronic interstitial nephritis with uræmia setting in at the late stage. Strict dietetic regimen, cathartics, diuretics, etc., of little avail. After being in bed for ten days, apathy, somnolence, twitching, and other cerebral symptoms developed, for which the hot pack and the hot-air bath were repeatedly ordered. No appreciable result was obtained, and muscular twitchings appeared, for which a fifth of a grain of pilocarpine was given hypodermically, in conjunction with the hot-air bath. About fifteen minutes later I saw the patient in collapse with rapidly increasing pulmonary oedema. No appreciable salagogue effect was noticeable, but a slight diaphoresis, though cold and clammy, covering forehead. The patient succumbed of cardiac paralysis with oedema of the lungs within two hours.

CASE III.—J. K., aged forty-eight years. Inebriate, with symptoms of alcoholic gastritis and diminished excretion of urine, which contained a trace of albumin, numerous granular and hyaline casts, and a specific gravity of 1.020. Bordering on the typhoid condition, with delirium, incoherence of speech, twitchings, and increased reflexes, he was treated for uræmia. Heart sounds normal; pulse 100°, with fairly high tension. Diagnosis: Chronic gastritis, cirrhosis of liver, chronic diffuse nephritis, with uræmic toxæmia. Vasomotor dilators, diuretics, cathartics, hot-air baths, etc., were resorted to without relief. Finally, increased impending nervous disturbances called for heroic measures, and a fifth of a grain of pilocarpine was given hypodermically. As in the two previous cases, collapse supervened: the pulse was fine, rapid, and intermittent, and there appeared symptoms of general venous stasis. A cold perspiration covered the face; pulmonary oedema rapidly set in, with quite marked salivation, which necessitated the laying of the patient on the side in order to allow the saliva to

escape. So marked was that that it materially expedited the dissolution, which occurred in about an hour. Atropine, camphor, and other cardiac stimulants were unable to neutralize the toxic effects of pilocarpine.

The rapidly uniform and fatal action following the use of pilocarpine in the above-cited cases, where apparently no contraindication for its administration existed, has incited me to raise my voice in protest against the use of this drug in the treatment of uræmia, for it has proved itself, not alone in my hands but in those of others, an untrustworthy and dangerous drug. Not in the least do I desire to disparage its use in some ailments where it has proved itself extremely useful and a valuable addition to our materia medica; but in the conditions enumerated above, where it jeopardizes the life of the patient, I emphatically protest against its further use. I doubt not that similar experiences could be recorded by others, were it not for the reluctance of offering our failures for just criticism. The loose statement of our text-books that this remedy may be employed with safety impress the reader that the drug may be resorted to with impunity. In Bright's disease, especially that form in which the circulatory appendages are involved, occurring generally in the senile state, we must reason that cardiac degeneration incapable of detection takes place, and if, for any reason, the use of pilocarpine may seem indicated, the drug should certainly be proscribed. When I was interne at Charity Hospital, the general routine treatment for uræmia was hot-air baths and pilocarpine injections, and I recollect cardiac failure and pulmonary edema were frequent causes of death, coming on shortly after its administration. Why it is that pilocarpine can be given with impunity in some diseases and should prove so dangerous in others, as in nephritis, I am not prepared to say, save that the general invasion of the vascular system by pathological processes produces cardiac changes which impair its energy, making it unable to cope with the depressing effects of the poison given. It has been established, and can not be controverted, that pilocarpine is a marked cardiac depressant and a dangerous remedy to administer in uræmia, that its sphere of usefulness is but a limited one, that it should be banished from our therapeutics of Bright's disease, and that its application should be relegated to another sphere.

970 LEXINGTON AVENUE.

**The Rush Medical College, of Chicago.**—Professor Edwin Klebs has been elected to the chair of pathology. We learn that the college has recently been recognized by the examining board of the Royal College of Physicians and the Royal College of Surgeons, of London, England. This recognition entitles its alumni to all the privileges accorded to the graduates of other institutions recognized by that board.

**A Medical Senator.**—The *Union médicale* says that Dr. Parisot has been elected a senator.

## THE BACTERIOLOGIST AND PATHOLOGIST IN MEDICINE.\*

By HENRY M. BRACKEN, M. D.,

PROFESSOR OF MATERIA MEDICA, THERAPEUTICS, AND CLINICAL MEDICINE,  
UNIVERSITY OF MINNESOTA.

EVERY medical man appreciates, or should appreciate, the importance of the study of bacteriology and pathology. Through their aid the diagnosis of disease may often be assured where formerly there would only have been a diagnosis by conjecture. They make the scientific treatment of disease possible. The physician or surgeon of the present day who is unable to utilize these scientific guides is in a pitiable plight. The medical schools, recognizing these facts, now make it possible for every medical student to acquire a sufficient knowledge of these subjects to serve him as aids in diagnosis when he enters upon his professional work.

But this is the age of specialization in medicine, and there are excellent reasons for specializing bacteriology and pathology. While the general practitioner may have sufficient knowledge of these subjects to use them in his daily duties, he may have neither the time nor the conveniences for going carefully into the necessary detail, and he should be glad to find those who are willing to devote their whole time to such scientific investigation, to whom he can turn for advice. As a matter of fact, these subjects are specialized, and we find in the bacteriologists and pathologists of the present day scientific consultants who should command at one and the same time our respect and their legitimate fees. The possibilities for carrying out such a line of specialization should be as great as in any other branch of medical work. But are they? Do the bacteriologist and pathologist secure proper recognition? I think not. How often do we meet with experiences quite similar to that of the following illustration: A physician with a doubtful case of pulmonary tuberculosis, where an absolute diagnosis without bacteriological investigation is impossible, but where an absolute diagnosis is of the greatest importance to the patient. The physician in charge sends a quantity of sputum to the bacteriologist for examination. The examination is made; a positive diagnosis is given. The patient is governed in his manner of life and place of living by the diagnosis of the bacteriologist and recovers his health. Both the patient and the attending physician should be very grateful to the bacteriologist for his opinion, which practically was the means of saving the patient's life. Notice now the amount of appreciation shown by them. The bacteriologist asks for a modest fee, with the result of calling down upon himself abuse from both physician and patient. The patient says: "I was quite satisfied with my attending physician and was quite willing to follow his advice without your opinion. I do not recognize your right to a fee." The attending physi-

\* Read before the Minnesota State Medical Society, Minneapolis, June 17, 1896.

cian says: "My dear sir, you have done nothing remarkable. I could have made the examination of the sputum myself had I dared to take the time, but I thought that you, with your laboratory conveniences, would be only too glad to do such a little thing as that as a matter of professional courtesy to me." The bacteriologist thus gets nothing but abuse for his painstaking work. The physician who has not been willing to reward science regards the scientist whom he has been treating in such an unprofessional manner with a feeling of contempt, and possibly of pity, because he prefers to follow such a life work rather than to make himself a practising physician. So, too, with the pathologist. He is not given his proper place. For example: A surgeon with a case requiring an operation is in doubt as to the proper course to pursue, or as to the probable outcome of an operation. He calls another surgeon to meet him in consultation over the case. The consultation may be of advantage to the attending surgeon; it may be of advantage to the patient; it may be of little benefit to any one. The consultant, however, is respected by the attending surgeon as well as by the patient and his friends. Without regard to the outcome of the consultation, the consultant expects his fee—often a good round one—and gets it. Contrast with this consultant the pathologist who may be called upon by the surgeon to clear up a doubtful diagnosis in a case where the true character of the disease should be known, if possible, before an operation is performed, in order that the surgeon may determine the limits and character of the operation to be performed. It may also be a case in which it is desirable that the patient or his friends should know the true character of the disease in order that matters of greater or less importance pertaining to the patient may be regulated accordingly. The pathologist, after making a most careful examination, requiring a great deal more time and quite as much skill as that given by the consulting surgeon already referred to in our illustration, gives an opinion that determines the action of both surgeon and patient. The attending surgeon, the patient, and the patient's friends are well satisfied with the pathologist's opinion. The pathologist sends in a request for a modest fee—quite modest as compared with the consulting surgeon's fee—thinking that of course it will be paid willingly. Not so. The patient says: "I did not care for your opinion. The responsibility was upon the attending surgeon. I had perfect confidence in him. It mattered little to me what the outcome of his action would be." The surgeon says: "The patient is quite right in objecting to your fee. It is outrageous for you to make such a charge. I asked for the examination simply out of curiosity. I would have operated without an opinion from you as to the true condition of the patient, and the result would probably have been quite as successful. I simply thought you would be pleased with the opportunity for making such an examination." Thus the poor pathologist goes

unpaid, while the consulting surgeon was well paid. And yet, of these two consultations just described, which had the greater probable value—the one which was only an expression of judgment or the one which was a statement of facts? It is thus, in too many instances, that the general practitioner stands to the scientific medical man. He recognizes and acknowledges the importance of scientific investigation; he appreciates the fact that he has neither the time nor the ability to make such investigations so carefully as can the man who gives his entire attention to scientific matters; but he is not willing to give the scientist the position of a consultant, so far as to demand for him his legitimate place and compensation. It is time that the bacteriologist and the pathologist were recognized as consultants of a high order. Their work requires their constant attention. They must be not only observers but investigators. The results of their investigations have much to do with our knowledge and treatment of disease. The medical man who chooses to follow the life of a scientist rather than that of a practitioner is generally making a financial sacrifice, and we should not increase this burden by expecting him to give us and our patients the benefit of his knowledge without compensation. We should show our appreciation of his work whenever we have opportunity.

So much for the relationship of the scientific specialist in medicine to the general practitioner. There is still another point of view from which we must observe him. One of the functions of State medicine is to prevent or limit the spread of infectious diseases among men and animals. For this purpose all suspected individuals should be subjected to a most rigid inspection. The statement that an infectious disease exists in a given case means the quarantine of the infected individual, or even, in cases of certain infectious diseases among animals, the death of the infected one. At best, quarantine is a hardship. It is often the cause of considerable financial loss. Interested parties have a right to demand a most careful examination of the suspected one before quarantine is forced upon them; an examination that in many instances can not be thorough without the aid of the bacteriologist. This fact is so generally recognized at the present time, that State and municipal boards of health appoint expert bacteriologists to investigate all suspected cases of quarantinable diseases among men and animals. Please notice the limit of responsibility of bacteriologists holding such appointments. It extends only to quarantinable diseases. We may demand of the State or municipal bacteriologist an inspection of tuberculous animals, because tuberculosis among animals is a quarantinable disease, but we have no legal right to ask for an investigation of a tuberculous suspect among men, because this condition is not yet classed as one subject to quarantine, and is therefore not under the control of boards of health. If such an investigation is asked for in the case of a human being, the bacteriologist is then in the position of a consultant, and should be recognized

as such. It is worthy of note, however, that tuberculosis among mankind, typhoid fever, and certain other diseases not yet subject to quarantine, can not too soon be placed, by the proper authorities, under the surveillance of the bacteriologist.

The appointment of bacteriologists for work of this nature should be more general. There ought to be a bacteriologist in every city or town throughout the State, in order that prompt examinations might be made when necessary. Of course, such work can be referred by local boards of health to the State bacteriologist, but this often involves a considerable loss of time. It might not be wise to ask of every local board of health the appointment of a salaried bacteriologist, but it should, when possible, appoint some competent physician to whom proper subjects for investigation might be referred. The State bacteriologist would then be in a position to advise and consult with the local bacteriologists. Many an outbreak of diphtheria or other infectious disease among men, or of tuberculosis, cholera, etc., among animals, might be prevented by the prompt action that would be possible were such appointments common. There is a danger from the appointment of incompetent men to fill these places of responsibility, but such dangers should not and will not exist when the medical profession fully appreciates its duty in preventive medicine. It is true that at present it is not always possible to find a competent bacteriologist in all places where an appointment should be made. Of course, under such circumstances no appointment should be made, for a poor bacteriologist is worse than no bacteriologist at all; he is a very dangerous quantity. This fact simply emphasizes the importance of our medical schools giving more attention to instruction in medical subjects bearing upon preventive medicine. In fact, a special course in State medicine should be a common feature of medical education. It is especially true in medicine that "an ounce of prevention is worth a pound of cure," and this fact should be impressed upon all sanitary authorities, upon the medical profession, and upon the laity.

#### SOME REMARKS ON THE PRINCIPLES OF TREATMENT OF SIMPLE ACUTE LARYNGITIS AND BRONCHITIS.\*

By THOMAS HUBBARD, M. D.,  
TOLEDO, OHIO.

THE purpose of my paper is to encourage authoritative discussion on a certain question, and it can best be served by a text and brief presentation of theories and clinical facts. The literature, both authoritative and current, is full of inconsistencies to the extent of obscuring the therapeutic principles involved.

The pathology of simple acute inflammation of the

upper and middle respiratory tract has received much enlightenment in this decade. We accept with modifications some of the theories bequeathed to us. They have the merit of having been tested by generations of practical clinicians, and form the basis of rational therapeutic principles. They may be briefly summarized as follows:

1. A congestive reaction following exposure to cold.
2. Hyperæmia due to irritation from dust and vapors.
3. Inflammation due to chemic irritation of the mucous membrane, from vicarious elimination of the products of disturbed tissue metabolism incident to certain systemic disorders, such as a general "cold," acute indigestion, lithæmia, and, in general, disturbances caused by suboxidation.
4. Reflex vasomotor disturbances and localized angioneuroses.
5. To these we now add inflammation caused by pathogenic micro-organisms and their products. These may be inhaled, or they may invade the larynx and bronchi from diseased foci of the throat and nose, or from systemic infection.

The term "expectorant" is full of beneficence. It is an excellent thing on general principles to cast out of the pectoral organ that which offends, and likewise the exfoliated cellular *détritus* and spent secretions. "Stimulating expectorant" is a still more felicitous expression. In the days when nauseant and relaxant expectorants were used heroically to unlock the emunctories, and when it was quite the rule to be made more sick in order to get well, stimulating expectorants were a Godsend. The puked, physicked, and phlebotomized patient welcomed a high degree of stimulation.

I will quote an old English medical aphorism as embodying my argument: "Never give stimulating expectorants until the skin is moist and the phlegm loose; it will do no good. You must give ipecac and relaxant expectorants as long as the skin is dry and the phlegm tough."

The gist of my contention is that we are losing sight of the proper relations of these two classes of expectorants, relaxing and stimulating. We are discarding inelegant nauseants, and using indiscreetly and irrationally the stimulating expectorants fortified by sedatives. This has been brought about in part through lack of confidence in the more agreeable relaxing expectorants in popular use, and through perfection in the application of local palliatives.

A few of the essentially conservative features of acute inflammation of a mucous membrane may be mentioned. Whether the cause is of the nature of a chemical irritant, self-produced, or a pathogenic organism, the ultimate object of determination of blood to the membrane is to flush away by sero-mucous flow the offending matter, and to antagonize the specific pathogenic agents by pouring out a host of resisting leucocytes.

\* Read before the American Laryngological Association at its eighteenth annual congress.

From the depths of the glands, and from the folds and interstices, mucus and serum, both aseptic and to a limited degree antagonistic to germ life, are poured out and flush the very substance of the membrane. This is the process called "loosening" the cough. We must keep clearly in mind these essential features of acute catarrhal inflammation, and I would add another very important consideration which applies to the tracheal and bronchial membrane especially. The swelling incident to hyperæmia and congestion of a membrane lining a more or less rigid fibrous and cartilaginous tube means necessarily a condensation of the superficial tissue elements of the membrane. As the calibre of the tube is encroached upon, a given number of epithelial cells must be crowded into a smaller area. This closes the orifices of the muciparous glands and checks mucous flow. Mucus retained in the substance of the membrane may undergo chemical changes, and become acrid and irritating, even though there be no specific pathogenic ferments present. This may cause even sapræmia. Much more injurious to the integrity of delicate epithelial cells are the ptomaines of specific germ origin. The only relief in either instance comes by inducing a free mucous flow.

There is a clinical fact in this connection of great practical importance. An acute inflammation of the respiratory tract is often progressive, much after the manner of erysipelas of the skin. Resolution may be well established in the larynx and trachea, and yet the bronchi may be in the acute stage. How very often our patients seem to have a loose cough and yet complain of a feeling of tightness and pressure over the bronchi! It is a good therapeutic maxim to direct the treatment according to the more severe condition. Neglect of this precaution encourages the development of a progressive capillary bronchitis or catarrhal pneumonia. When the larynx is in the primary acute stage, and the bronchi are in the relaxed condition and secreting freely, the prognosis for quick recovery is more favorable. Often we find that the larynx is being constantly reinfected from an unhealthy throat and nose, and once the tide of mucous flow is established from bronchi toward the throat the larynx is relieved, and speedily recovers the normal condition.

The important processes tending toward recovery are, first, a free flow of mucus and serum from the substance of the membrane, and, second, rapid expectoration. Secretions retained in the larynx and bronchi ferment and irritate the membrane. The fact is reaffirmed that we have two distinct classes of therapeutic agents with which to meet the special indications above mentioned. The skillful use of those first indicated—namely, to encourage free secretion—is the *sine qua non* of successful treatment. The too early use of stimulating expectorants encourages rather the absorption of the inflammatory products than a natural elimination. They are expectorants only after free secretion is established.

Alteratives, astringents, stimulating vapors, and antiseptics have all one predominating effect on an acutely inflamed mucous membrane, which obscures any special therapeutic influence. They are all irritants, and in varying degree antiseptics. We may add that stimulating expectorants are likewise irritating except under certain conditions to be mentioned.

The secondary effect of an irritant on mucous membrane is, as a rule, to produce a sero-mucous flow depleting the tissues. When iodine, alumnol, or nitrate of silver preparations are applied to an acutely inflamed mucous surface, the more delicate epithelial structures are offended, and the membrane weeps in self-defense. Coagulated mucin and incorporated cells, and likewise pathogenic organisms, are flooded away and antagonized. They may be called depletory antiseptics. Tissue congestion is relieved, and the symptoms may be temporarily, very rarely permanently, alleviated. As a rule, the ultimate damage to the membrane is more than the beneficial effect of lessening congestion and removing a part of the offending material, and the reaction which follows is worse than the original condition.

A class of remedies which may appropriately be called vasomotor stimulators, or arterio-capillary contractors, has come into prominence recently, more especially in the treatment of acute laryngitis. Cocaine, atropine, strychnine, and hydrastine are the more commonly used. In mild cases not associated with bronchitis or pharyngitis they may be depended on, and relieve many symptoms, but in more severe cases their use, local and internal, may retard that natural process of resolution which is the first step toward recovery.

Sedatives and local anæsthetics, such as opiates, cocaine, and menthol, should be used with caution. Opiates dry the mucous membrane and thicken the mucus. The effect of cocaine is pernicious. Menthol gives only very transient relief. The best sedative to an inflamed larynx is a flow of non-irritating bronchial mucus. All treatment should be directed toward this end, and all palliative treatment which retards it should be avoided.

Keeping the principles expressed in the precept of Fothergill clearly in mind, the first thing to determine is the choice of a relaxing expectorant. Ipecac is excellent, but very slow in action in ordinary doses. It usually destroys appetite. Vascular sedatives, such as the tartrate of antimony, lobelia, and aconite, produce so great a degree of vasomotor depression and general relaxation that copious diaphoresis is encouraged, and the patient catches more cold, aggravating the condition for which it was given. They may be administered only when the patient will remain in bed, and the same may be said of pilocarpine.

For about five years I have been using apomorphine, freshly compounded in acidulated mixture, and regard it as the best of all relaxing expectorants. In one-thirtieth-grain doses, at two or three hours' intervals, it rarely fails to cause a free sero-mucous flow in twelve

to thirty-six hours. In cases of severe laryngitis and bronchitis rest is an essential adjuvant. Appropriate general treatment is, of course, implied. Codeine sulphate in one-fifth-grain doses, given independently *pro re nata*, is the best sedative.

Apomorphine in acidulated mixture rarely causes nausea in the doses mentioned, and in fact seems rather to aid digestion and increase the appetite for a limited period. It is slightly laxative. It can be given for many days in doses gradually decreasing as the expectoration becomes more free. Since using this remedy I find less and less use for stimulating expectorants and sedatives. The apomorphine should be administered as long as improvement is decided. A sero-mucous bronchial secretion is coughed out very easily. Only in debilitated subjects, or where there is a broncho-pneumonia, have I found it necessary to supplement this treatment with stimulating expectorants. Of these I regard the carbonate of ammonium as the best, administered in a mucilaginous vehicle or as the fresh aromatic spirits.

A clinical study of this question of relative values and indications for relaxing and stimulating expectorants, and a review of the literature over a considerable period, has prompted me to present this paper. I may add that, in fact, the comparison of results in my own practice, and also in cases under the care of others, strengthens my conviction that the aphorism of Fothergill concerning the use of expectorants is sound, and, further, that in just so far as we have drifted away from it have we deteriorated in our principles of therapeutics of simple acute laryngitis and bronchitis.

## THE PROPHYLAXIS OF NASAL CATARRH.\*

By CARL SEILER, M. D.,  
PHILADELPHIA.

THERE is no doubt in the mind of any laryngologist and rhinologist that what is generically known as nasal catarrh is due primarily to two principal causes; in fact, if I may be permitted to state my opinion, that in reality there is but one primary cause which produces this prevalent disease, and that the other is merely a predisposition called into activity by the one.

To quote the opinions of the different authors would be but a waste of time and labor, because a careful scrutiny of their writings has convinced me in the opinion which I have just expressed. They may differ apparently in their interpretation of the causes of simple nasal catarrh, merely in the sense in which I use the term; namely, not depending upon an acquired constitutional or systemic dyscrasia or disease, and in its causation by accidental lesions sustained in later life. I therefore feel justified in my belief that the well-understood causes producing acute inflammation of the anterior and pos-

terior nasal mucous membrane lay the seed for pathological changes in that very mucous membrane, and with every reproduction or recurrence of the acute or subacute (begging to differ with Bosworth) subsequent exacerbation can have but one result, and that is an increase of the pathological changes in the mucous membrane and the turbinated tissue of the nasal chambers. Even but a hasty review of the geographical and anthropological statistics of the prevalence of this disease in different climates and among various people, if followed out to its logical conclusion, must lead the careful observer to doubt that the disease in question is one which is not amenable to prophylaxis, but that modern civilization and modern civilized methods of rearing children, together with the long-continued, baneful inherited proclivities and hygienic prejudices, merely confirm the conclusions arrived at by the student of ancient as well as modern anthropology in its relation to modern diseases.

We must therefore logically look for the earliest causes of nasal catarrh in childhood, in children of civilized nations, in the cities, in the habitation and methods of rearing of children by so-called civilized plans of overclothing, overfeeding, and overcaretaking. It is not only the overheating, overfeeding, and overcare which do the harm; it is the method and unsystematic bringing up of children which cause one attack of simple coryza to run into another, and thus become a subacute catarrh; and also the superstition and indolence of mothers, as well as of the general practitioner, who smother the poor infant that has a cold in its head with flannels and blankets even in the midst of summer, and deny Nature's best remedy—fresh air—dosing it with drugs and antiseptics, and neglect cleanliness and pure asepsis. No wonder that the poor sufferer barely recovers from one cold in the head before he is attacked by another; and no wonder that the pathological changes result by accumulation through such repeated inflammatory processes in hypertrophic changes of the turbinated tissue, or, if any systemic inherited dyscrasia be present, speedily changes it into the atrophic form. It is therefore the duty of the medical adviser to instruct the parents in the preventive measures which should be instituted to prevent this prevalent disease, and it is the general practitioner more than the specialist who is at fault in this matter of carelessly encouraging parents in their neglect by telling them that the child will outgrow the disease; and it is also, therefore, the duty of the specialist, who, above all, is most intimately acquainted with the baneful effects in after life of such neglect, to instruct the general profession.

As already indicated in the foregoing remarks, cleanliness not only of the whole body, but of the nasal cavities in particular, whether a cold in the head is present or not, is the primal and most important prophylactic measure that can and should be instituted to prevent recurrence of acute coryza, prevent accumulation, in-

\* Read before the American Laryngological Association at its eighteenth annual congress.

spissation, and putrefaction of mucus, and then finally prevent systemic infection by the ingestion of the products of putrefaction in the most susceptible system of a child.

In dentistry for a long time this same principle of cleanliness has been insisted upon by the dental surgeons, and they have successfully instructed the parents in taking care, with brush and powder, tooth washes and antiseptic lotions, of not only their own but their children's teeth, to prevent decay, so that the general practitioner—except in remote country towns—is but rarely called upon to extract decayed molars, and the ravages of neglected dental caries, which but a quarter of a century ago were so common, are but rarely seen nowadays even among the least educated classes of our citizens.

Why, therefore, should not the rhinologist follow in the footsteps of the dental surgeon, and bring about in like manner so marked a diminution of this still commonly supposed incurable disease—nasal catarrh—by prophylaxis? It is no more difficult to teach a child to cleanse the nostrils and anterior cavities with an appropriate wash than it is to teach him, as is done in every family, to use the toothbrush; and we all know that the only difficulty encountered is the prejudice of the parents and the natural abhorrence of the child to such a procedure, which, however, are no greater obstacles than the dental surgeon had to encounter in his instituting a reform.

As in all such matters of reform, it is necessary, however, to first instruct the teacher and make him understand the necessity and the all-importance of adhering to the strict observance of minute details in the carrying out of the method to be employed; and I will therefore hastily sum up my opinions as to the best methods to pursue in preventing the growth and development of nasal catarrh in both its forms—hypertrophic and atrophic—in children; that is to say, the simple, uncomplicated, non-traumatic form of the disease, because the others, of course, need more than hygienic and prophylactic measures.

Let therefore a child, as early as possible in life, be taught to snuff up the nose a warm saline or alkaline solution, with or without the addition of antiseptics, either from the hollow of the hand or from a small cup or glass, three or four times morning and evening, and let no amount of prejudice or recommendation by advertisements or other pressure brought to bear upon the parents allow a douche or atomizer or other artificial appliance to be substituted for this natural method of nasal cleansing; because, in the first place, the natural method being more readily applicable to the child's nature, avoids the natural abhorrence of instruments of any kind in the child's mind; and, second, because they are in most instances either ineffectual in accomplishing the purpose of thoroughly cleansing the nasal cavities, or else are, if they do accomplish the purpose, harm-

ful, as in the case of the douche, by the inordinate pressure of the solution upon the organ.

Also let the solution be of not only a chemically non-irritating quality, but also of such temperature and specific gravity that overheating or chilling of the nasal mucous membrane and osmotic action producing pain and sneezing are avoided.

Of course, antiseptics may be added to the solution at the discretion of the physician to prevent putrefaction and self-inoculation with septic material.

As important, however, as this nasal cleansing is the proper feeding and clothing of children, so that overheating of the general system may be avoided, and the skin, especially around the neck and arms, be so hardened by cold-water applications, in the form of sponging morning and night, that moderate exposure will not readily give rise to acute coryza.

Our American children in particular are, in my opinion, as a rule too much clothed, too much confined indoors, and overfed with heat-producing food, so that when they have left the nursery they are mere hothouse plants, and it takes a long course of outdoor sports with boys to inure them to exposure, with a number of often serious effects of exposure, upon the respiratory organs in particular, to make them strong and healthy; and even then, in many instances, the seeds for nasal obstruction and consequent impairment and weakness of the respiratory tract having been sown in the nursery develop into the more remote effects, and particularly phthisis, so that it is not an uncommon observation that many of our athletic college youths, after having graduated, settling down in business for life, are attacked with phthisis or tuberculosis, which was kept in abeyance only by the outdoor exercise which they had at college.

Of course, I could go on to enumerate indefinitely the well-known hygienic rules and maxims, and the baneful effects of their non-observance, but I have said enough, I hope, in my plea for the intelligent and persistent reform by the laryngologist and the physician in the bringing up of children with a view of in a great measure preventing nasal catarrh and its consequences.

## SOME OBSERVATIONS IN LARYNGEAL TUBERCULOSIS.\*

By S. OAKLEY VANDER POEL, M.D.

LARYNGEAL tuberculosis is both a extension and an extension of pre-existing disease. It is a *pyrexia*, because, when clearly established by laryngoscopic examination, there is no doubt that the lungs either are or will shortly become tuberculous, if not obviously so at the time; it is an extension of a disease, because, as a rule (not invariably, although it may be so), the pulmonary tissue first becomes the seat of tubercu-

\* Read before the American Laryngological Association at its eightieth annual congress.

lar growth, mischief appearing subsequently in the larynx.

The question of the order of time or priority existing between laryngeal phthisis and pulmonary phthisis seems to be clinically fairly well established, for most practitioners recognize it as a rule that laryngeal ulceration is preceded by a destructive pulmonary affection; and, according to my experience, I should designate it as a rule that has few exceptions; for the careful examination of the apices of the lungs with reference to the air they contain, and especially with regard to their comparative height, is of cardinal importance in determining this question. The flattening of one apex as compared to the other, as was pointed out by E. Seitz, of Giessen, permits one to recognize slight cicatricial contractions of the parenchyma at a time when the patient, without regard to this point, must have been pronounced sound, as to his lungs, as even the signs of catarrh of the apex and of diminished air contents may fail in individual cases.

It can not, however, be positively denied that exceptions to this rule do occur. For, as Buhl\* contends, "Nothing wonderful is to be found, *a priori*, in such an appearance of laryngeal phthisis, as in a well-pronounced phthisical constitution the first eruption may take place in some other organ than just in the lungs, and sometimes does so take place; and furthermore, we can not deny the possibility that pieces of detritus thrown off by the laryngeal ulcers, and coarser pieces of tissue, may be drawn into the lung during inspiration and here produce phthisis." But from my own clinical experience I would assert that such an order of development is certainly extremely rare.

I would ask your attention, for a few moments, to the consideration of some of the more obscure points in the symptomatology of tuberculous laryngitis.

We occasionally meet with cases of consumption in which there is simple weakness of voice, in which speaking is effected with great effort, and is often reduced to a whisper, or in which voice is completely abolished. This occurs without any organic change in the larynx, examination showing that the tensors of the vocal cords are weakened, the cords appearing shortened and shriveled, the larynx contracting round its centre in attempted vocalization. It thus resembles the aphonia of hysteria, the chief point of difference being that in the latter case the adductors are usually affected and not the tensors, although this difference is not invariable. The fact that both laryngeal nerves arise from the vagus may account for the liability of either set of muscles becoming thus paretic from irritation of the pulmonary branches of that nerve. Trousseau mentions this "nervous aphonia" in cases of pulmonary tuberculosis.

With reference to these motor disturbances which occur here so often, as has been pointed out by Rud

Meyer, "We must distinguish between the muscular paresis which is so frequent at the beginning of laryngeal disease, and which appears to depend on the general anæmia of the soft parts within the larynx, and the paralysis of the right vocal cord, dependent upon paralysis of conduction of the right recurrent laryngeal nerve, which is often found imbedded and constricted in the hard, thickened pleural tissue about the apex of the right lung." The former, as has been demonstrated, may be quickly removed by appropriate treatment, while paralysis of the recurrent laryngeal, just described, is inaccessible to treatment. We have also to notice the existence of muscular paresis in the final stages, when inflammatory cedema has infiltrated the submucous tissue. This may be explained by the cedema interfering with the mobility of the crico-arytenoid articulations, at the same time causing mechanical hindrances to the locomotion of the arytenoid cartilages.

In some cases of pulmonary tuberculosis which have come under my observation I have been led to believe that there are certain premonitory symptoms in the larynx of a catarrhal character that portend the later development of laryngeal tuberculosis. I refer to cases when, at the time, there are no discernible manifestations of the tubercular process. Bosworth contends that a chronic catarrhal process in the larynx does not predispose to tuberculous disease of the organ; that they bear no definite relation to each other, either causative or otherwise; that the influence, therefore, of a chronic laryngitis as a predisposing cause of tuberculous disease is probably greatly overestimated, although it is undoubtedly true that a phthisical patient, suffering with a chronic laryngitis, is more liable to develop tubercular action than one in whom the laryngeal membrane is in a state of health. In this view I am inclined to concur; still, as I stated, the cases to which I refer showed symptoms which I have come to recognize as preliminary to the development of tuberculous trouble. In my cases there was at first no evidence of ulceration or of tumefaction of the posterior laryngeal wall, so characteristic of the later stages, but merely a slight thickening of the mucous membrane associated with the presence of a white, milky, somewhat purulent, mucous fluid, which secretion contains as yet no tubercle bacilli, but which I have come to consider almost pathognomonic. This secretion is chiefly to be found lodged about the aryteno-epiglottic folds, or may coat the interior of the larynx. This catarrhal condition I have seen to persist for six weeks or two months before the characteristic train of symptoms so common to the later stages developed. Then the subjacent membrane often is covered by minute white points, and when scarified they yield very little blood.

A case in point occurred in the person of a young man, twenty-five years of age, who had been the subject of pulmonary tuberculosis for three years, the disease being limited to the right apex, but which had progressed

\* In Sommerbrodt, *loc. cit.*, p. 265.

to the formation of a cavity. He had spent two years in the Adirondacks, which residence had been attended by great amelioration of all his pulmonary symptoms. Cough and night sweats had disappeared; he had gained fifteen pounds in weight; an examination of the chest which I made in August, 1894, in the Adirondacks, showed the cavity to be healed, there were no bacilli in the sputum, and I looked upon the case as one of cured phthisis.

In the following November he presented himself at my office complaining of aphonia, with slight hacking cough. His general condition was favorable, with no return of his old symptoms, and an examination of the sputum was negative; the larynx, however, presented the appearance just described—laryngeal mucous membrane slightly swollen, of a dull gray color, and coated in part with a milky-white, somewhat purulent mucous fluid. It was not thick or tenacious and was readily removed by the spray. Repeated bacteriological examinations failed to disclose the tuberculous bacilli. The secretion was chiefly to be found lodged about the aryano-epiglottic folds. This condition of larynx continued for some six weeks, when it gradually assumed the typical picture of a tuberculous larynx. A further residence in the Adirondacks was of no avail and the case terminated fatally in a few months. When the disease involved the epiglottis, this shriveled and rendered deglutition difficult and painful, while if it were much ulcerated, food would find its way into the larynx.

Tuberculous infiltrations may occur over the arytaenoid cartilages and subsequently soften, or ulceration may occur in the vocal cords, chiefly at their posterior insertions. Frequently, however, the cords escape when there is most extensive ulceration elsewhere. Aphonia may be produced by very little mischief; but, on the other hand, ulceration, unless it attack the vocal cords, may be extensive without there being much aphonia. The prognosis in these cases, notwithstanding the operative interference which of late has been so much in vogue, is still somewhat disheartening.

#### OBSERVATIONS UPON EYE DISEASES AND BLINDNESS IN THE COLORED RACE.\*

BY J. MORRISON RAY, M. D.,

CLINICAL PROFESSOR OF OPHTHALMOLOGY AND OTOLOGY,  
UNIVERSITY OF LOUISVILLE,  
OPHTHALMIC SURGEON TO THE SAINTS-MARY AND ELIZABETH  
AND CITY HOSPITALS.

The negro we must have with us, therefore a study of his propensities to disease and the peculiar characteristics of certain forms when affecting this race is a legitimate field for discussion. The interest centred upon them in a social and political relationship with the whites demands that they shall have their history established

and recorded. The medical men of the localities where they are most abundant should carefully study their demologic peculiarities, basing their investigations as near as possible on incontrovertible facts and scientific data.

Most practitioners of experience are acquainted with certain pathological and aetiological peculiarities presented by negroes. In a general way their tendency to thoracic diseases, tuberculosis in all its manifestations, the acquired and inherited results of syphilis, and their lessened powers of resistance to diseases of the colder latitudes, is familiar to every physician.

The surgeon is aware of the frequency of fibroid tumors, and the tendency to keloid development in the race. On the other hand, family practitioners know the power of resistance this race presents to the forms of miasmatic diseases prevalent in the warmer climates, and many surgeons of large experience have never seen a case of epithelioma in a negro. Billings, in a statistical study of the influence of race on disease, states that the colored race is shorter lived, has a higher infantile mortality, is especially liable to tuberculosis and pneumonia, and less liable to malaria, yellow fever, scarlet fever, and cancer. It is well proved that, subjected to the same environments, the adult negro is less resistant to disease than the adult white. Miserable homes (from a sanitary standpoint), combined with poverty and ignorance of the laws of hygiene and personal care, should furnish a fertile field for the propagation of diseases of a bacterial nature.

Most eye diseases are of such a character as can be looked upon directly, and the different phases of many forms of inflammatory action noted. Thus a study of eye diseases in this race presents many interesting features. While aware of a number of these characteristics, my attention was first drawn to the subject by an interesting comparative study by Dr. Swan M. Burnett, of Washington. Since his paper appeared, I have constantly kept a record of observations with the hope of eventually drawing some comparisons from them. This I have attempted in a preliminary manner in the material offered at this time.

The negro as we find him in this locality is not the negro found in the cotton fields and sugar plantations of the extreme South; rarely do we observe one that does not show the infusion of Caucasian blood. Notwithstanding this attenuation, he presents certain peculiarities in the study of eye inflammations that are not the result of accident or environment.

At my request, Dr. Crittenden Joyes has carefully tabulated, from the records of our clinic at the University of Louisville, one thousand consecutive cases of eye disease, exclusive of defects in refraction, as they presented themselves for treatment previous to May 1, 1896. This includes both the white and colored cases, the proportion being 579 whites to 421 colored, and is a sufficient number for our present purpose.

\* Read before the Kentucky State Medical Society, June 14, 1896.

Comparative Table of 1,000 Cases of Eye Disease (Condensed).

	Whites.	Negroes.
Diseases of the lids.....	90	50
"    "    cornea.....	80	107
"    "    conjunctiva.....	276	149
"    "    iris, ciliary body, and chorioid.....	35	70
"    "    lens.....	31	22
"    "    muscles.....	34	6
"    "    optic nerve and retina.....	14	6
"    "    eyeball and orbit.....	7	4
unclassified.....	12	7
Total.....	579	421

In a review of the comparative tables offered, a number of interesting points are apparent.

The first question that presents itself for solution is the comparative frequency of eye diseases in the two races. Is the negro more often subject to eye diseases than the white? This question seems difficult of a satisfactory answer, since it is impossible to obtain the exact number of each race from which our material for study was drawn. The white race in Kentucky outnumbers the colored nearly six to one. Yet we know that in charitable and clinical work this proportion does not prevail, a much larger comparative percentage seeking aid in such institutions being negroes. The only information obtainable that points toward a greater prevalence of eye disease in the negro is that furnished by the United States Census Bureau. If we accept this as accurate, we find that proportionately the number of blind in the State is greater among the negroes, being for the whites 1 in 960; for the colored, 1 in 843. Kollock asserts that in South Carolina blindness is rampant among the negroes.

A point of great interest furnished by our table of statistical comparison is the relative frequency of different eye diseases in the two races. This reveals the fact that the negro race is remarkably prone to certain forms of eye inflammation, and, on the other hand, presents an apparently complete immunity from certain others.

Of the 1,000 cases tabulated, there were 140 cases of lid troubles found. The negro does not show a single case of trichiasis or entropion, and of seven cases of epithelioma all were in whites. On the other hand, hordeola, chalazia, and eczema were noted as fifty per cent. more common in the negro.

Affections of the conjunctiva furnished 425 cases—276 white, 149 colored. In a study of these a most noticeable feature is the much larger percentage of the phlyctenular variety of conjunctivitis in the negro, and the practically complete immunity of the black to trachoma, only 2 cases being recorded to 63 in the white. These two cases were diagnosed by some of the assistants, and were in all probability cases of folliculosis, or so-called follicular trachoma—a form of conjunctival inflammation that at certain stages of its development is very much in its clinical appearance like true trachoma, yet never presents corneal involvement or cicatricial bands in the palpebral conjunctiva. I am of the

opinion that, while this form is sometimes found in the negro, it is exceedingly rare.

Burnett, in Washington, Theobald, in Baltimore, Baldwin, in Montgomery, and others have verified the findings of the statistics here gathered with reference to the immunity of the negro from trachoma. It appears inexplicable that such a disease as trachoma, the bacterial origin of which seems conclusively proved, and which observation teaches is undoubtedly contagious, should show an aversion for the conjunctiva in the negro. Even if, as is maintained by some, an underlying blood dyscrasia is necessary for its foundation (the so-called lymphatic diathesis), as alleged by Noyes, we see no reason why the negro should escape.

The last word has not been said about this most interesting and oftentimes destructive form of eye inflammation. Why it should follow such a different clinical course in different subjects, often attacking an entire family in an isolated community, or why we see so many in whom for years the inflammation confines itself to one eye, are points upon which further knowledge is required before the question can be settled.

That form of conjunctival inflammation that often prevails during the warm season, and familiarly named summer trachoma, or circumcorneal hypertrophy of the conjunctiva, appears to be as frequent in the negro as in the white. These records show it to be slightly more so, and I am sure during the last few years I have seen a larger proportion of such cases in the colored race. This affection, while often giving very much the appearance of both trachoma and follicular conjunctivitis, is undoubtedly a distinct disease.

In the study of corneal diseases, as presented in the table under consideration, there were found 187 cases—80 white, 107 blacks. Corneal inflammation more often than any other form of eye disease is apt to be the result of some vicious constitutional diathesis. Therefore, we should expect a large preponderance of these diseases among the colored. Our statistics show that they are forty per cent. more common in the negro.

The variety of corneal disease most rife is that form of relapsing destructive ulceration characterized as phlyctenular or strumous. Unlike what is true of the whites, this ulceration is as often found in the adult as in the child. That portion of the eye commonly known as the uveal tract, iris, ciliary body, and chorioid, furnished us in our study 105 cases—35 whites, 70 negroes. Out of 58 cases of acute iritis, 43 were in blacks. Of these 43, 33 were shown to be syphilitic. The iris and ciliary body are the parts of the eye usually first showing the ravages of syphilis, and the negro seems to be many times more prone to this complication. Saussure asserts that seventy per cent. of the negro population of the South either inherits or acquires syphilis.

In the study of iris diseases in the negro, our statistics prove a point we have for a long time noted and emphasized—namely, the peculiar proneness for gum-

matous infiltration to accompany the inflammation. Of six cases of gumma of the iris found, all were in negroes. Not only is the iris frequently the seat of such formation, but the only cases of gumma of the ciliary body that have come under my personal care have been in this race. It has been stated that syphilis in the negro does not present itself in the malignant form often seen in the whites, and that it responds more quickly to proper treatment. With this observation the teachings of the statistics presented do not agree. The forms of syphilitic iritis and cyclitis, with extensive condylomatous developments quickly ruining the eye, are found most often in this race, and, while they respond promptly to proper treatment, the inflammation has usually been of such a violent nature as to destroy the usefulness of the organ before the constitutional effect of the remedial agent has been obtained.

Diseases of the crystalline lens offer 53 cases for study—31 whites, 22 negroes—showing no great difference in the tendency to cataract development in the two races. The optic nerve and retina furnish 20 cases for consideration—14 whites, 6 blacks. Of these six, five were cases of primary atrophy of the optic nerve. The frequency with which non-inflammatory optic atrophy is found in the negro is familiar to all, many of them being cases in which it is impossible after thorough examination to find the cause for its development.

Affections of the eye muscles were found most common in the white race. The point of interest gained from these cases was with reference to the statement that has been made that the negro was practically exempt from uncomplicated squint, and, when present, that it was secondary to some intra-ocular disease or corneal macula. While it may not be found in so large a proportion of cases as in the whites, it is by no means uncommon, being in the relation of one to five in the whites. There are no reasons, from a study of this subject, why we should not find as many cases of convergent squint among the colored race as among the whites, since the same conditions that are the underlying factors in squint are present in both races.

The cases upon which these observations were based were gathered as they presented themselves for treatment, and do not include all the cases we have seen. Exclusion was made of those offering for correction of some defect in refraction, preferring to base our study on eye inflammations and diseases alone. Since the negro has been thrown upon his own resources, the struggle for existence has increased his exposure to diseases that lead to eye complications. The extra amount of work thrown upon this organ subjects it to the same demand as the eye of the white race, without the same vital power of resistance.

Further evidence of the prevailing causes of blindness in this race may be gained by a consideration of the colored inmates of the State institution for their educa-

tion at Louisville. These I was permitted to examine by Professor Hunkton. I found of 39 cases, wards of the State, that 51.3 per cent. were blind from diseases that affected the cornea primarily, and of these 33.3 per cent. were from so-called scrofulous keratitis. In the same institution, of 155 whites examined, 18.1 per cent. were blind, the result of trachoma and its sequela, while the colored children did not present a single instance resulting from "granular lids."

*Tabulated Report of Colored Blind Cases at the Kentucky Institute for the Blind.*

	No. of cases	Per cent
Keratitis, phlyctenular . . . . .	13	33.3
Purulent ophthalmia . . . . .	7	18.0
Congenital and lamellar cataract . . . . .	4	10.3
Iridocyclitis . . . . .	5	12.8
Atrophy of the nerve . . . . .	4	10.3
Retinitis pigmentosa . . . . .	1	2.6
Nystagmus . . . . .	1	2.6
Traumatic and sympathetic . . . . .	3	7.7
General disease (small-pox) . . . . .	1	2.6
	39	100.0

A consideration of the material I have here gathered for study, while not disclosing anything new to most of those familiar with the subject, certainly furnished evidence in support of the statement that the negro race will be found to suffer to a greater percentage from the graver forms of eye disease than the white, and that certainly in this State blindness is more prevalent than among the whites. Further, that a well-defined difference exists in the two races in their proclivity to certain forms of eye disease, the negro being particularly liable to the destructive forms of corneal disease and to the varieties of iritis accompanied by condylomatous developments. On the other side, he presents a peculiar, indescribable immunity from that form of contagious conjunctivitis familiarly known as "granulated lids," and a lessened liability to cancerous growths in this locality. Eye diseases as a class follow a more disastrous course, and consequently a larger number of blind are found.

## Therapeutical Notes.

**The Necessity of Rest in Bed in Influenza.**—In Dr. J. F. Goodhart's article on Influenza, in the first volume of Dr. Thomas Clifford Allbutt's new *System of Medicine*, we find the following:

"There is no specific yet at hand for this disease. This is quite certain from the number of drugs that have been regarded as almost infallible by one observer and another. All are agreed, however, that mildness of attack and speedy recovery are best insured by taking at once to bed, and that it is the worst folly to struggle on with work and to attempt to fight the disease—a plan that, although some came through successfully, was nevertheless the cause of the loss of many lives."

**Terror in Bronchorrhœa.**—The following case is related by Ram Dhari Sinha, V. L. M. S., of the Civil Hospital, Rajputana, in the *Indian Medical Record* for June 1st: The patient, a man sixty-five years old, had suffered from bronchorrhœa incidental to pulmonary phthisis for six years. The average discharge was from two to three pints in twenty-four hours. He appeared very weak, anæmic, languid, and despondent. His eyes were watery and injected. He could hardly digest his meals, and there was a violent paroxysmal cough with watery expectoration. A physical examination elicited rhonchal fremitus, harsh, rough breathing, and sonorous rhonchi, with mucous râles toward the inferior angles of the scapulae.

The previous treatment had consisted of the use of De Jonghe's cod-liver oil, Kepler's emulsion of cod-liver oil with malt, Scott's emulsion of cod-liver oil with hypophosphites of sodium and calcium, and a number of patent pectoral syrups, but there had been no permanent benefit. The cod-liver oil had impaired his digestion and caused diarrhœa, dyspepsia, and constitutional weakness. The author prescribed terror in drachm doses three times a day, and after the third day all the distressing and annoying symptoms began to subside. Within six weeks the patient had gained both weight and strength, and at the time of the report was performing his work as usual.

The author states that he has employed this remedy in seven cases of chronic bronchitis, in two of pneumonia, and in one of phthisis, and that he has always found it answer better than any other remedy, so he recommends it to the profession. It has no taste or odor; it does not disturb the stomach and bowels and it is not nauseating; furthermore, it increases the appetite and helps digestion.

**Subcutaneous Injections of Cocaine.**—In the *Gazette hebdomadaire de médecine et de chirurgie* for June 28th there is an article on cocaine by Dr. G. Maurange in which, among other things, he calls attention to the occasional occurrence of such accidents as vertigo, pallor, and a tendency to faintness after injections of even the smallest amount of cocaine. To obviate these occurrences, he advises that the patient should be lying down when the injection is administered, that a solution not stronger than of one per cent. should be used, and that care should be taken not to throw the injection into a vein.

**Aristol in the Treatment of Burns.**—Dr. Paul Walton (*Wiener medicinische Presse*, 1896, No. 24; *Deutsche Medizinisch-Zeitung*, June 22, 1896) reports that for a year he has employed aristol powder systematically in the Hôpital civil in Ghent in all cases of burns, including the most extensive ones, and with very good results.

**Electricity in the Treatment of Vomiting.**—According to Dr. G. Apostoli (*Bulletin officiel de la Société française d'électrothérapie*, 1895, No. 4; *Centralblatt für Gynäkologie*, June 27, 1896), galvanization of the pneumogastric nerve is an effective remedy for the habitual vomiting of hysterical and pregnant women. The electrodes are placed between the insertions of the sterno-cleido-mastoid muscles, and a current of from five to fifteen (rarely twenty) milliamperes is passed for from five to fifteen minutes, or even for an hour or more, until a result is obtained. The application is made after a meal, once or twice a day at first, at intervals of several days as improvement advances.

THE  
NEW YORK MEDICAL JOURNAL,  
A Weekly Review of Medicine.

Edited by  
FRANK P. FOSTER, M. D.

NEW YORK, SATURDAY, JULY 18, 1896.

THE UNRECOGNIZED CONSULTANT.

PROFESSOR BRACKEN did well to put before the Minnesota State Medical Society, at its recent meeting, the subject of The Bacteriologist and Pathologist in Medicine in an aspect that has been too commonly ignored, that of their title to proper remuneration as consultants in cases in which their special knowledge and skill are called upon to settle a doubt in diagnosis. Dr. Bracken's paper will be found elsewhere in this issue of the *Journal*. We hope it is not often that such rudeness is displayed toward pathologists, microscopists, and bacteriologists as figures in the retorts that Dr. Bracken gives as specimens of what they get when they request payment for their services. There can be little doubt, however, that, rudeness or no rudeness, the value of their investigations is rarely appreciated as it should be or that they are in any way rewarded for their pains. This is all wrong, as Dr. Bracken most forcibly points out. The case ought to call only for statement to be admitted, for no argument worthy of the least consideration can be brought against it.

Two reasons suggest themselves as accounting for the feeling that bacteriologists, pathologists, and microscopists should be content to work without pay, but not as in the least justifying it. One of these is the fact that, while the practitioner is ready enough to bow down before the discoverer or the great investigator in bacteriology, pathology, or microscopy, he has no such feeling for the routine worker in those branches, one who merely applies the knowledge he has obtained from others. Go to, then, O successful and popular practitioner! Where are your discoveries? What evidence can you give us that you have made profound original investigations or are any better than the laboratory plodder? What are you doing in your daily practice beyond applying the knowledge others have taught you? You answer that you are constantly using your reasoning powers, rather than applying humdrum tests, and that the faculty of reasoning is loftier than the combination of carefulness and keenness of perception that rule in the laboratory. Are you not deceiving

yourself just a trifle? Do you really think that a human machine—a being possessed of a stock of special information and endowed with the sense of method—is what you can depend on to set you right in the face of difficulties? Confess, now, that the bacteriologist, the pathologist, and the microscopist are constantly operating nerve centres quite as high as those that guide your footsteps, and are quite as much entitled to good round fees. Consider the chemist. Surely he does not work out of courtesy to you or as your satellite or vassal. Even the anæsthetist, who of old was the youngest doctor or student that could be found, and was expected to find his remuneration in viewing the operation, of which he could generally see little if anything, is now a man who to-morrow may be your peer, and feels that he may. He now presents his bill with as much confidence as you present yours, and with as good reason; and he is paid.

The other occasion of a little loftiness on the part of the practitioner toward the laboratory man is perhaps the mercantile idea—true enough, God knows—that the rub is, not to do the work, but to get it to do. He is the great man who gets the patients; any second-rate fellow might carry them well enough through most of their illnesses or show accuracy enough in diagnosing them with the aid of laboratory appliances; hence he, the great man, is entitled to all the remuneration. But see the fallacy of this notion, to say nothing of its unworthiness; if it applied, the physician or surgeon called in in consultation would find himself obliged to rest content with a pittance or perhaps with the pleasure of observing an interesting case, and we all know that he does not find himself in any such plight. There is, then, no good reason why our friends of the laboratory should not be looked upon as real consultants and treated accordingly. Let them take heart and insist on substantial remuneration, and they will get it. Moreover, the more they get for their services the better will they be appreciated.

#### MARRIAGES OF CONSANGUINITY.

M. PAUL PERRIN has made the consequences of the marriage of near relations the subject of his graduation thesis, and the substance of his argument is given in the *Gazette hebdomadaire de médecine et de chirurgie* for July 2d. He classifies the various opinions held in regard to these marriages as follows: 1. They are almost always unfortunate in their results, and should

be absolutely interdicted. 2. They are in no way harmful, and should be permitted and even recommended. 3. Their influence is good or bad according as the parties are free from constitutional diseases or affected with them; consequently, they are to be permitted or interdicted according to the state of the case.

M. Perrin then considers some of the numerous diseases that have been imputed to such marriages. Idiocy, insanity, and epilepsy, he says, are most commonly inherited, but there are cases in which nothing but consanguinity seems to explain their occurrence. As to infantile convulsions, the causes of them are so numerous that it is impossible to fasten upon this as one of them. Consanguinity may play a part in the production of deaf-mutism, but not constantly. In certain affections of the eye, such as albinism and pigmentary inflammation of the retina, its influence has been observed and, in the case of albinism, pretty definitely proved. M. Perrin does not think that sterility can be imputed to consanguinity pure and simple. If, he says, both the husband and the wife come from large families, their union will probably be very fruitful; if, on the other hand, they are only children, there is a great probability of their remaining childless. In regard to certain congenital deformities, such as polydactylism and clubfoot, they have so often been observed in the children of related parents who were in good health and of good constitution that we are forced to admit the influence of mere consanguinity.

Returning to the three opinions mentioned, M. Perrin says of the first of them, that almost all marriages of consanguinity are productive of unfortunate results, that it is not justified; there is some truth in it incontestably, but it does not take heredity sufficiently into account, and therefore can not be supported. The second goes to the opposite extreme, and charges everything to heredity. Consanguinity and heredity are two parallel ætiological circumstances; they may conspire in the same family to bring about identical morbid consequences, but, on the other hand, the one may exist without the other. So this second opinion must be rejected, notwithstanding the fact that consanguinity in the lower animals generally results in excellent progeny. The third opinion comes nearest to the truth, and may be agreed to with the reservation that in some instances consanguinity of itself alone may exert an unfortunate influence on the children.

The physician who is consulted on the subject may be guided by the following considerations: If the parties

and their parents have no diathesis or any hereditary disease, if they are in full health, of strong constitution, and under favorable climatological and hygienic conditions, the physician should not advise against the marriage, but he should not encourage it, for quite a number of unions fulfilling these requirements have resulted in children presenting serious and irremediable defects. If, however, the physician discovers the least trace of any physical or mental abnormality, he should use his whole influence to prevent the marriage; in cases of concurrent heredity the results would surely be deplorable.

### MINOR PARAGRAPHS.

#### A NEW JOURNAL OF LARYNGOLOGY.

A MONTHLY journal called the *Laryngoscope*, devoted to diseases of the nose, the throat, and the ear, begins its career with the July number, which contains seventy-two large octavo pages of reading matter well printed and well illustrated. It is edited by Dr. Frank M. Rum-bold and Dr. M. A. Goldstein, of St. Louis. The staff of associate editors consists of Dr. M. D. Lederman, of New York, Dr. S. Scott Bishop, of Chicago, Dr. W. Scheppegrell, of New Orleans, and Dr. F. B. Eaton, of San José. A corps of foreign editors is made up of Dr. J. Dundas Grant, of London, Dr. Victor Urbantschitsch, of Vienna, Dr. J. J. Kirk Duncanson, of Edinburgh, Dr. A. Hartmann, of Berlin, Dr. J. K. Kimura, of Tokio, and Dr. G. Sterling Ryerson, of Toronto. The editors state that their intention is "to fill the niche between the strictly special and the general journals with that class of physicians who confine themselves entirely to the treatment of the diseases mentioned or who pay special attention to these troubles while maintaining a general practice."

#### A NEW BELGIAN JOURNAL.

We have received the fifth number of volume one of the *Annales de l'Institut Ste. Anne*, of Brussels, edited by Dr. C. Jacobs, with the assistance of Dr. Thiebaud, Dr. Godart, Dr. Devos, Dr. Borremann, and Dr. Bonneville. It appears to be devoted to gynecology. The number before us is profusely illustrated.

### ITEMS.

**Infectious Diseases in New York.**—We are indebted to the Sanitary Bureau of the Health Department for the following statement of cases and deaths reported during the two weeks ending July 14, 1896:

DISEASES.	Week ending July 7.		Week ending July 14.	
	Cases.	Deaths.	Cases.	Deaths.
Typhoid fever.....	15	3	17	7
Scarlet fever.....	70	7	51	8
Cerebro-spinal meningitis....	2	3	6	4
Measles.....	149	7	194	11
Diphtheria.....	237	37	221	36
Tuberculosis.....	116	121	95	90

**Compulsory Reports of Infectious Diseases.**—Some months ago, Dr. Samuel C. Busey, of Washington, delivered an annual address as president of the Medical Society of the District of Columbia in which he said:

"The experience of the present year has clearly demonstrated the necessity of some compulsory legislation requiring every physician to report to the health department every case of zymotic disease occurring in his practice. No system of sanitation or preventive medicine can be effective without the knowledge of the number and location of every such case of disease, at all times of the year, and more especially during the prevalence of an epidemic. If every case of typhoid fever that has occurred in the District during the present year had been promptly reported to the health department, the fair fame and healthfulness of this city would not have been tarnished by the exaggerated and detrimental reports which have been spread all over the country, and the cases due to milk and water infection and soil pollution could have been classified with almost absolute accuracy. There would have been fewer cases and a lower death-rate. The constantly reiterated statement that this or that family or 'my people' would not permit such reports is a fallacy unworthy of respectful consideration, when the mortuary columns of the local press are teeming with reports of distress and sorrow that bring home to every household the inadequacy of municipal protection from preventable diseases. Every good citizen will willingly submit to a law that offers protection from sorrow, suffering, expense, deaths, and funerals."

**The Buffalo Academy of Medicine.**—The secretary, Dr. Irving W. Potter, announces that the officers of the medical section are desirous of obtaining the titles of any communications which will be offered during the coming year, and it is requested that the titles and the date preferred by the writer be sent to the secretary before August 1st, in order that the programme for the year may be completed.

**The Richmond Academy of Medicine and Surgery.**—At the last regular meeting on July 14th, the order for the evening was a paper on Typhoid Fever, by Dr. W. S. Gordon.

**Change of Address.**—Dr. J. M. Ray, from No. 414 West Chestnut Street to No. 423 West Chestnut Street, Louisville.

**Army Intelligence.**—*Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from July 5 to July 11, 1896:*

BACHE, DALLAS, Colonel and Assistant Surgeon-General, Headquarters Department of the Platte, is granted leave of absence for two months, to take effect on or about July 15, 1896.

**Naval Intelligence.**—*Changes in the Medical Corps of the United States Navy for the Week ending July 11, 1896:*

BRODERICK, R. G., Assistant Surgeon. Ordered to the U. S. Steamer Franklin.

GRAVATT, C. U., Surgeon. Ordered to Norfolk with draft of men, then home, and granted three months' leave of absence.

LOVERING, P. A., Surgeon. Detached from the New York Naval Hospital and ordered to the U. S. Steamer Oregon.

**LOWNDES, C. H. T.**, Passed Assistant Surgeon. Detached from the Washington Navy Yard and ordered to the Naval Hospital at Philadelphia.

**LUNG, G. A.**, Passed Assistant Surgeon. Detached from the U. S. Steamer Thetis, ordered home, and granted two months' leave of absence.

**MARMION, R. A.**, Medical Inspector. Detached from the Board of Inspection and Survey and ordered to the Washington Navy Yard.

**WISE, J. C.**, Medical Inspector. Detached from the Washington Navy Yard and ordered as a member of the Board of Inspection and Survey.

**WHITE, S. S.**, Passed Assistant Surgeon. Detached from the Naval Academy and ordered to the U. S. Steamer Thetis.

#### Society Meetings for the Coming Week:

**MONDAY, July 20th:** Hartford, Conn., Medical Society; Chicago Medical Society; Cleveland Society of the Medical Sciences.

**TUESDAY, July 21st:** Ogdensburg, N. Y., Medical Association; Syracuse, N. Y., Academy of Medicine; Medical Societies of the Counties of Kings and Otsego (annual—Cooperstown), N. Y.; Baltimore Academy of Medicine.

**WEDNESDAY, July 22d:** American Microscopical Society of the City of New York; Medical Society of the County of Albany, N. Y.

**THURSDAY, July 23d:** New York Orthopaedic Society; Pathological Society of Philadelphia.

**FRIDAY, July 24th:** Cleveland Medical Society.

### Births, Marriages, and Deaths.

#### Married.

**FLEMING—NAMMACK.**—In New York, on Wednesday, July 8th, Dr. David P. Fleming and Miss Katherine Nammack, sister of Dr. Charles E. Nammack.

**MAXWELL—PRICE.**—In Meridian, Mississippi, on Thursday, July 9th, Mr. Caldwell Maxwell and Miss Mamie Price, daughter of Dr. C. S. W. Price.

**SMITH—ANDERSON.**—In New York, on Wednesday, July 8th, Mr. Alfred Keene Smith and Miss Kitty Anderson, daughter of Dr. J. Anderson.

**WHITFIELD—TUTTLE.**—In Avon, N. Y., on Tuesday, July 7th, Dr. Arthur Whitfield, of London, England, and Miss Marguerite Tuttle.

#### Died.

**BROWNLEE.**—In San José, California, on Wednesday, June 24th, Dr. J. D. Brownlee, aged seventy-six years.

**DUNN.**—In Yazoo City, Mississippi, on Thursday, July 9th, Dr. Richard L. Dunn.

**GIBBS.**—In Fort Ann, N. Y., on Monday, July 8th, Dr. Theron Z. Gibbs, aged sixty-five years.

**HOPE.**—In New York, on Tuesday, June 26th, Dr. J. S. Hope, of the United States Navy.

**NEELER.**—In Kahoka, Missouri, on Friday, July 3d, Dr. Samuel Neeler, in the sixty-fifth year of his age.

**PEEPLS.**—In Jackson, Mississippi, on Wednesday, July 8th, Dr. R. W. Peepls, in the sixty-fourth year of his age.

**SEXTON.**—In New York, on Saturday, July 11th, Dr. Samuel Sexton, in the sixty-third year of his age.

**STUMP.**—In Utica, N. Y., on Friday, July 10th, Norman J. Stump, only child of Dr. William Stump.

### Letters to the Editor.

#### REFLEX EPILEPSY.

SHELTER ISLAND, N. Y., July 10, 1896

*To the Editor of the New York Medical Journal:*

SIR: Your issue of July 4, 1896, containing Dr. Peterson's letter regarding reflex epilepsy was forwarded to me while in pursuit of pleasure and health.

I trust that in the fall I may have sufficiently recovered from "mental blindness," to which Dr. Peterson seems to think I am at present a victim, to give him all the facts that he challenges me to unearth from medical literature.

Prior to so doing, however, I deem it wise to correct some statements made by Dr. Peterson regarding my personal work upon epileptics, and to call attention to some other paragraphs in his letter that might mislead the general reader, although it is difficult to treat them otherwise than as a jest.

In the first place, Dr. Peterson charges that I have alleged a cure of twenty per cent. of twenty-six cases of epilepsy treated by me through eye treatment alone, and that my records do not justify this statement.

I have ('tis true) reported in detail only twenty-six cases. Of these, twenty-five were reported some years ago, and one last April.

In the summary of the last article (to which I referred Dr. Peterson) I say that up to the date of that article twenty per cent. of my cases of epilepsy had apparently been cured.

Does Dr. Peterson think that only one case of epilepsy (the one reported last April) was all that I had seen in several years; or does he fail to discern the difference between a "recorded" case (in my record books) and a "reported" case? Such little oversights seem to be of no importance in Dr. Peterson's efforts to convict his opponent of "mental blindness."

In the second place, Dr. Peterson "quotes authorities" to sustain his weak position, but fails to mention that he wrote letters to physicians who had sent patients to me (as I suggested he might do) and received at least one report that the patient in question had been entirely free from epilepsy for three or more years.

Dr. Peterson knows, as well as I, that he might quote authorities for centuries back to cast discredit upon methods of treatment that happened either to be unknown to the authors cited, or concerning which the authors cited knew absolutely nothing personally, and whose opinions were therefore based upon second-hand information.

How many of the clinical cases of Dr. Peterson or those observed by others whom he mentions were ever subjected to eye treatment in the hands of any oculist with a large experience in the treatment of heterophoria?

In the third place, Dr. Peterson begins apparently to fear to meet the array of cases that will surely be brought sooner or later to his notice, when he says that he will exclude in his count of authentic and trustworthy cases all in which the existence of "genuine epilepsy" is not well established.

This is no new idea! The same move has been made before by other neurologists to defeat justice to this new method of treatment of functional neuroses, and with what results? Are not certain oculists who originally scoffed at heterophoria to-day operating frequently upon the eye muscles for nervous diseases in New York city? Is recognition (either tacit or in print) not steadily increasing among the oculists of this country and Europe?

Later on, I may conclude to publish some interesting letters received by me from oculists of prominence in various cities upon this point, as well as from some of the leading medical men of Europe, exhibiting the deepest interest in this new field of work.

I should like Dr. Peterson to put in print just what he intends to exclude as not "genuine" cases of epilepsy. Are all genuine cases to be those that did not get well, and is some other term applicable to those in which the patients recovered? Is this fine distinction to be hereafter exercised on all cases in Dr. Peterson's clinic and others, with proofs of the "genuine" type of every case, or is it to be reserved as a weapon to annihilate (with one sweep) all reported cases of restoration to health by eye treatment?

Would it not be sad to think of a judge on the bench giving out decisions in *ex-cathedra* fashion on questions of vital moment after he had thrown out or destroyed all the evidence that failed to establish his preconceived judgment? Is it not amusing to discuss, even for an instant, the possibility of evidence being so tampered with, suppressed, or distorted?

Finally, Dr. Peterson once more endeavors to escape the facts that he expects to meet later by offering the absolutely ridiculous explanation that in any cases where eye treatment has cured "genuine" epilepsy (if such an admission were possible) he must attribute success purely to suggestion—a sort of permanent mental hypnotism of the patient.

Even this explanation is not new! It was lately hashed up and dressed in attractive garb by Dr. Casey A. Wood, of Chicago (*New York Medical Journal*), and my letter in reply is to be found by Dr. Peterson in a later issue!

It is really hard for me to be serious in discussing so absurd an argument. The operation of a graduated tenotomy is absolutely painless; it is often performed by me upon children while they chat with me over their dolls or toys; it does not confine the patient to the bed or prevent any reasonable amusement or occupation more than a few hours; it is not looked forward to by my patients with any dread (as a rule); and it is purposely made light of by me, both prior to and after the operative step, in order to decrease alarm or apprehension.

In my reply to Dr. Casey A. Wood, I made use of about these words:

"A good spanking or a dose of castor oil has ten times the mental suggestion of a graduated tenotomy; yet who ever recorded a cure of epilepsy or other grave neurosis from such a method of treatment with the hope of causing mental suggestion?"

In closing, I would say to Dr. Peterson and others who are really anxious to gain information concerning my methods and results (for scientific ends) that I have nothing to conceal or to fear; and I should be happy at any time to aid them by all means in my power.

Those of us who are earnestly engaged in this new field of neurology and optics are, however, in this work to stay. I am sure that an earnest, painstaking, and con-

scientious investigation of heterophoria will repay all who closely follow the latest methods. Never before in the history of medical science has the investigation of the eye muscles been placed upon so accurate and scientific a basis. The practical results of this work in relieving suffering humanity are creating naturally an enthusiasm among those who are proficient in this field; but not so great, I trust, as to cause them to be "misled by the personal equation" or to affect their reasoning faculties.

AMBROSE L. RANNEY, M. D.

#### BALSAM OF PERU IN THE TREATMENT OF SCABIES.

SAGINAW, MICH., June 9, 1896.

To the Editor of the *New York Medical Journal*:

SIR: It is scarcely worth notice, I suppose, but Dr. Coggeshall, in the *Journal* for June 6th, intimates that I made a mistake when I stated that Waring, in his *Therapeutics*, referred to the use of balsam of Peru in the treatment of scabies. Possibly he has a different edition of Waring. Mine is the third American edition, of 1874, and on page 132, paragraph 371, he *does* state: "In scabies of children, Dr. Monti, of Vienna, has successfully employed frictions with this balsam," referring to balsam of Peru in the preceding paragraphs. I did not intend to say I had used it in scabies, but that it was not a new remedy in that disease. I have found it greatly relieve pruritus in eczema. I may say here that the *Half-yearly Abstract of the Medical Sciences*, vol. xlv, 1867, refers to the *New York Medical Journal* for February, 1867, as authority for the statement that Burchardt, of Berlin, had used the balsam of Peru "against itch with great success."

So far as I can find, Waring nowhere mentions the use of copaiba in scabies. I believe the doctor needs new glasses.

S. E. CAMPBELL, M. D.

#### THE ANTITOXINE TREATMENT OF DIPHTHERIA.

CHICAGO, July 6, 1896.

To the Editor of the *New York Medical Journal*:

SIR: Not so much in defense of antitoxine—which hardly needs any—as in common justice to its "manipulators" in this city, as your correspondent, Dr. Nolan, styles them in his letter published in last week's *Journal*, I ask your publication of the inclosed statement of the facts in the case he therein refers to.

F. W. REILLY, M. D.

[Copy.]

CHICAGO, July 6, 1896.

F. W. REILLY, M. D., Assistant Commissioner of Health.

"DEAR DOCTOR: Referring to the letter in the *New York Medical Journal* of July 4th by Dr. W. J. Nolan, of 285 Loomis Street, I find by the notes in my visiting list I was called on May 27th to that case by Dr. Bergeron, who had been called and, finding it was a severe case of diphtheria, referred the people to me, saying he would prefer not to treat diphtheria. On my arrival I found the case extremely severe, advanced beyond the fourth day, Klebs-Loeffler bacilli, also streptococci and staphylococci in abundance, and every evidence of septicæmia. I gave an unfavorable prognosis, but injected antitoxine with a forlorn hope, and also immunized all the other (five) children in the family.

"Then I was informed by the mother that Dr. Nolan had been called on Sunday, May 23d, made his second visit on Monday, and then abandoned the case. There-

upon they sent for Dr. Bergeron and by him the case was referred to me. The case was strictly a charity case and so known to be by Dr. Bergeron, and I was compelled to furnish medicine at my own expense. The child died as I predicted on my first visit. None of the children immunized contracted the disease. The mother, who was not immunized, contracted diphtheria, was treated with antitoxine, and promptly recovered.

"I did not see the case nor was antitoxine administered until May 27th, the second day after Dr. Nolan had abandoned it. The mother—'the defenseless widow'—had given him the last dollar she had in the house. She is eminently satisfied with what I did for her child, as are all the family, and unstinted in her condemnation of Dr. Nolan for his 'heartless neglect,' as she terms it.

"Respectfully submitted,  
"E. P. MURDOCK, M. D.,  
"Medical Inspector."

#### EXTRAGENITAL CHANCRE.

To the Editor of the New York Medical Journal:

SIR: In your issue of June 6th are reported five cases under the title of Extragenital Chancre.

I think all those who have had much experience with syphilis will see at once that only one of these cases was an initial lesion.

Case I, with a large indurated growth of the finger, could not have been a chancre, because the patient had deep ulcerations of the tonsils and pharynx and perforation of the hard palate, making it a case of tertiary syphilis.

Case II, with a large indurated sore of the index finger of the right hand, and at the same time an ulceration of the tonsils, is, again, a case of tertiary syphilis.

Case III is a plain case of secondary syphilis.

In Case IV there were a sore on the tip of the tongue, mucous patches, and some deep ulcerations. The sore on the tip of the tongue was certainly not a chancre, because the patient could not have had a deep ulceration and chancre at the same time. It was a case of secondary syphilis passing into the tertiary stage.

In Case V, the woman showed a red, glazed induration of the lower lip, of about the size of a small English walnut. I believe this woman had an initial lesion, and that she contracted it by kissing her husband.

I can not agree that the author saved the child from having syphilis by giving the mother hot bichloride douches. The child was born with syphilis, and it was a mistake not to allow the mother to nurse the child, and in this way control the disease in the child by giving the mother syphilitic treatment.

The intensity of the disease in the child will depend upon the time the mother was infected.

The child, unless treated for syphilis, will without doubt break out with the disease, although it may enjoy apparently good health for a long period.

Case VI was that of a married woman with a sore just above the right knee. Here, again, is a tertiary ulceration of the leg mistaken for an initial lesion. This patient had ulceration of the mouth, with intense headaches.

The cases of mine, reported in the *Journal* for May 23d by Dr. E. Harrison Griffin, were all verified by the roseola. If the same precaution had been taken with these cases, they would have all been thrown out except Case V.

J. CLARENCE SHARP, M. D.

## Proceedings of Societies.

### AMERICAN GYNÆCOLOGICAL SOCIETY.

*Twenty-first Annual Meeting, held in New York, on Tuesday, Wednesday, and Thursday, May 26, 27, and 28, 1897.*

The President, Dr. WILLIAM M. POLK, of New York, in the Chair.

*(Continued from column 101, page 700.)*

**The President's Address.**—The PRESIDENT, in his address, reviewed some of the important events that had transpired in connection with the development of gynecology during the twenty-one years of the society's existence. He said that shortly before the birth of the society the field of gynecology had been largely dominated by the cervix, and gynecological practice had appeared to consist chiefly in the use of the cylindrical speculum and the stick of nitrate of silver. In referring to the more important advances that had been made, he enlarged upon the results of Emmet's labors for the prevention and cure of fistula, upon the recent methods for inspecting the bladder and ureters, upon the surgical operations that had been devised for the relief of retrodisplacements of the uterus, and upon the investigations into "surgical fever," and closed his sketch by drawing a vivid picture of the awful ravages of puerperal fever in former days and of the doubt and dread that had pervaded the lying-in chamber.

**The Technics of Vaginal Hysterectomy.**—Dr. PAUL SÉGOND, of Paris, presented, in the French language, a communication on this subject, which was interpreted by Dr. Henroin. He said that he recognized laparotomy as a tried and valuable method of treating septic diseases of the abdominal cavity, and that vaginal hysterectomy was adapted only to a certain class of cases. If there was any doubt about suppurative pelvic disease being bilateral, abdominal section was preferable. There had been numerous modifications of vaginal hysterectomy, but still the operation remained essentially as it had been originally devised by Péan. All the operative procedures, he said, should be done under the guidance of the eye, and in rare instances, where no line of cleavage between the uterus and adjoining organs could be found, the operation must necessarily be incomplete. In his six hundred operations he had not met with a single vaginal hernia, and the vaginal operation not only furnished a complete cure in almost all instances, but contributed very materially to the comfort of the patient, and entirely avoided the abdominal scar. In these six hundred operations he had wounded the bladder six times. It was most liable to be wounded at the time of making the first incision, anterior to the cervix, or just as one was about to open the abdominal cavity. By pulling the cervix backward and forward, one could recognize the situation of the bladder, and by avoiding the use of lateral retractors this accident would be for the most part prevented. He preferred to use a short retractor, which was very gently held against the anterior surface of the uterus. In the cases in which the rectum had been injured, he had always found that healing had been prompt and complete. The most serious consequences followed the wounding of the ureter, which was an accident most prone to occur, either while dissecting back the bladder and anterior vaginal wall or later on, during the efforts to control the hemorrhage. In his cases he had wounded the ureter only twice. He attributed this comparative freedom from the accident to the use of his circular inci-

sion and the lateral incisions, to the avoidance of retractors, and to careful denudation anteriorly. To guard against hæmorrhage, he required his patients to remain in bed for two weeks after this operation, and unless there was a distinct indication for its removal, he allowed the gauze packing to remain unchanged for from five to eight days. He did not remove the forceps for forty-eight hours.

**The Relative Merits of Total or Partial Hysterectomy for Cancer of the Cervix by Ordinary Methods and Supravaginal Excision by the Galvano-cautery.**—Dr. JOHN BYRNE, of Brooklyn, read this paper. He expressed the conviction that the frequent publication of so-called successful hysterectomies, and rarely of the unsuccessful ones, had wrought almost incalculable evil, but the pendulum appeared to be already swinging toward the conservative equilibrium. In twelve hundred and seventy-three colpo-hysterectomies, done by thirty-eight surgeons, both here and abroad, the average primary mortality was 14.6 per cent. In the short space of three years there had been no fewer than a hundred and sixty-three vaginal hysterectomies for cancer in one institution, and at the end of three years only twenty-five per cent. of the patients were living. Twelve per cent. were reported to be still without recurrence. In forty cases that he had operated upon for cancer by supravaginal excision with the galvano-cautery knife, those that he had been able to follow, the average period of exemption from recurrence had been nine years, while in one apparently unpromising case the patient reported herself to be in perfect health at the end of nearly twenty-one years. Dr. Byrne alleged the following advantages for his method:

1. Exemption from traumatism of the parts supposed to be sound.
2. An almost total abolition of the primary mortality.
3. Prolonged immunity from recurrence.

Dr. R. STANSBURY SUTTON, of Pittsburgh, said that he was convinced from the histories of some of his own cases that cases which we occasionally believed to represent a very bad form of cancer were in fact not cases of cancer at all. For true cancer, he was of the opinion that it made but little difference whether the cautery or the ligature was used, for in this country, where we did not usually see cases of cancer until a late stage, recurrence would be the rule. Regarding the removal of fibroids, he had become so convinced of the advantages of the Pryor or Baer operation for large fibroids that he did not care to resort to morcellation through the vagina. In the case of small fibroids, he preferred at present to do an anterior colpotomy, enucleate the fibroid, and, if possible, return the uterus to the pelvic cavity.

Dr. J. E. JANVRIN, of New York, said that, according to his experience, in only about one fourth of the cases of cancer of the uterus did the disease begin in the cervix. He had recently published a paper giving his ultimate results in sixteen cases in which the cancer had begun in the cervix. In these cases he had operated from three years and four months to twelve years ago, and thirty-three and a third per cent. of them had been absolutely cured. His experience had been that when the disease returned in the cicatrix the amount of pain experienced was much less than from the primary disease.

Dr. W. H. WATHEN, of Louisville, said he did not think it was often that more than one retractor was needed at a time in performing vaginal hysterectomy. Where the disease was unilateral, he believed, the diseased tube and ovary could be removed through the vagina with less danger and mutilation than through the abdomen.

Dr. HOWARD A. KELLY, of Baltimore, said that the vaginal sectionists had abandoned the conservative field in the treatment of the appendages and of fibroids. It was not possible by the vaginal route to decide upon what structures could be saved with the same facility as by abdominal section. He also thought the vaginal field must be abandoned for carcinoma, because this disease could be more effectively combated through the abdomen. There was, however, one great advantage of the vaginal operation, and that was that, if the aseptic procedures were faulty, there was less danger to the patient than from an abdominal operation. He had found that morcellation greatly simplified the operation, and also that the careless handling of the retractors was apt to lead to injury of the ureters. Where the patient was exhausted by sepsis, if the pus could be readily evacuated through the vagina, this was the better route to select. In cases in which the uterus was adherent, he certainly would not undertake the vaginal operation.

Dr. MATTHEW D. MANN, of Buffalo, said that in selecting the route we should be guided by the variety of cancer present. Where the vaginal wall and the broad ligaments were not involved in the cancer, or where the disease was confined to the body of the uterus, and this organ was freely movable, the vaginal route was the better one, but these cases represented the minority. As these cases of malignant disease were usually not seen until late, an extensive dissection would ordinarily be required, and hence for these the abdominal route was better.

Dr. A. PALMER DUDLEY, of New York, in comparing the methods of Jacobs and Ségond, said that the healing by the former was slow, owing to the use of the cautery, and that for this reason he preferred Ségond's. In his opinion, when it became necessary, in cases of carcinoma of the uterus, to make the extensive dissections indicated by Dr. Kelly, it was better to refrain from operating altogether.

Dr. BACHE MCE. EMMET, of New York, said that he had found retractors very useful in vaginal hysterectomy. He presented a special clamp that he had devised for use in cases in which a good deal of the work had to be done by the sense of touch. These clamps were so constructed that by simply bringing together the distal ends of the blades they were locked.

Dr. FLORIAN KRUG, of New York, contrasted the present discussion, in which there had been no dissenting voice as to the propriety of removing the uterus in cases of bilateral suppurative disease, with the controversy which had occurred in this society over the same subject only two years ago.

Dr. FORD, of Utica, said that he had been impressed with the fact that in Ségond's original paper removal of the uterus had been recommended for the purpose of giving easier access to the diseased annexa. Even admitting the uterus to be a useless organ, it should not be condemned solely on this account, and he was glad to see that in this country there was a tendency to save it.

Dr. HENRY C. COE, of New York, referring to Dr. Byrne's paper, said that he had become a pessimist concerning the treatment of malignant disease. Very poor results were obtained in cancer of the breast, even by those of much skill and experience in this special field, and the discovery that even after the most extensive operations nodules having a structure suspiciously like that of carcinoma were found did not afford even the most ardent operator much encouragement. Some time ago Dr. E. C. Dudley had argued in favor of using

clamps in operations for malignant disease, on the ground that the resulting sloughing process served to destroy groups of cells beyond the incision made by the knife. If this argument was valid, then there was good reason to believe that the galvano-cautery might possess a value hitherto unappreciated.

Dr. STEPHEN C. GORDON, of Portland, Me., said that it was his practice to do an abdomino-vaginal operation in cases of cancer of the uterus, because the vaginal portion of the cervix could be readily removed through the vagina. The operation could then be completed through the abdomen, and the uterus drawn back through the vagina, thus avoiding the danger of infecting the tissues with the disease. As to the removal of fibroids, he still favored the abdominal operation, for, although he could see little enough by that route, he could see much more than by the vagina.

Dr. BAHR, of Philadelphia, said that if he could believe that the uterus was a useless organ when the appendages were extensively diseased, and also that it was not important to retain the cervix, he would resort to the vaginal operation.

Dr. J. M. BALDY, of Philadelphia, said that a very important objection to vaginal hysterectomy was that it produced a shortening of the vagina amounting to nearly an inch and a half.

(To be continued.)

### Book Notices.

*The Primary Factors of Organic Evolution.* By E. D. COPE, Ph. D., Professor of Zoology and Comparative Anatomy in the University of Pennsylvania. Chicago: The Open Court Publishing Company, 1896. Pp. xvi-547. [Price, \$2.]

THIS book is an accumulation of the results of earnest and painstaking investigation into the regions of biology and paleontology.

From the latter a large amount of evidence is drawn, thus making the work very valuable, especially in view of Professor Cope's wide knowledge in this department of science.

In comparison with most other works on evolution, this fact is at once to be remarked. As the author states, the rapid strides of paleontological research in this country have brought to light masses of facts which have a direct bearing on the subject.

A large share of the references are from American authors, and the writer naturally gives prominence to the views of those who, from the amount of material at their command, should be the better informed.

Professor Cope enrolls himself with the so-called Neo-Lamarckians, whose views are an elaboration of the principles laid down by Lamarck in the early part of the century. Their aim is to find a cause or reason for the variations which, inherited, finally produce new forms, rather than to regard all variations as accidental, "promiscuous, and multifarious," as Darwin does.

The book is divided into three parts: The nature of variation, the causes of variation, and the inheritance of variation.

Under Part I are chapters devoted to variation, phylogeny, parallelism, and catagenesis.

Under Part II are chapters on physiogenesis and nat-

ural selection, and a very strong and interesting chapter on kintogenesis, especially the parts treating of the manner of the evolution of various articulations and forms of teeth in vertebrates.

Part III comprises chapters on heredity, the energy of evolution, the function of consciousness, and the opinions of Neo-Lamarckians.

In the various chapters numerous proofs are brought forward to sustain the axioms advanced, and they are very well grouped and arranged.

The book, although extremely interesting to any one, is better adapted to the student than to the cursory reader. This in itself tends to show the advance of the science of evolution, which does not now so much rest upon a conglomeration of theories as upon a solid foundation of facts.

*Les Artérites. Leur rôle en pathologie.* Par A. BRault, médecin de l'Hôpital Tenon, etc. Paris: G. Masson, 1896. [*Encyclopédie scientifique des aide-mémoire.*]

THIS work is one of a large series of short treatises on various scientific subjects now being published in Paris, and intended, when complete, to form an encyclopædia of the various sciences.

The present volume gives an interesting and fairly complete presentation of the subject of diseases of the arteries. The conversational and argumentative style adopted by the writer might easily lead one to underestimate the real scientific character of the work. The author first describes at length the gross and microscopical characters of lesions of the arteries, and it is to be noted that some points are here properly emphasized which are not usually detailed in text-books of pathology. The chapter on pathogenesis is most valuable and interesting. Here the author reviews three theories advanced in explanation of the "plaque jaune." The first attributes its formation to a granular degeneration of the superficial layers of the intima; the second, to a new formation of connective tissue in the intima; the third, to obliteration of the vasa vasorum which ramify in the adventitia. After an interesting and convincing argument, the writer accepts the second as the correct theory. In regard to the exact point of origin of chronic arteritis, this observer states that he has never seen isolated periarteritis or mesarteritis, but that lesions limited to the intima are of common occurrence. He finds no gross or microscopical differences in the lesions produced by syphilis and those arising in the arteries from other causes.

In the etiology of arteritis chief importance is given to acute articular rheumatism, but the arteritis of typhoid fever is discussed at some length.

Syphilis, tuberculosis, malarial disease, small-pox, saturnism, alcoholism, and gout are separately reviewed in their relation to the arteries, and finally the experimental production of endarteritis is described from the work of several French investigators. The author's own experiments indicate that infection, to be followed by endarteritis, should be preceded by traumatism of the wall of the vessel or a disturbance of its nutrition. Thoma's theory of the origin of arteritis is not mentioned.

A short concluding chapter relates to symptomatology.

*Water Supply.* Considered Principally from a Sanitary Standpoint. By WILLIAM P. MASON, Professor of Chemistry, Rensselaer Polytechnic Institute, etc.

First Edition. First Thousand. New York: John Wiley & Sons. London: Chapman & Hall, Limited. 1896. Pp. vii-504.

It has given us much pleasure to read Professor Mason's work, and we have derived much benefit from the reading. The book is one which may well be commended, not merely to the professional but also to the lay reader, for it is free, for the most part, from exclusive technicality and therefore may be comprehended and enjoyed by all who are interested in the subject. As the author very frankly says, the work is largely a compilation and had of necessity to be so, but it contains, too, much that is original, the union of the two elements providing us with a work on water supply which we think it would be difficult to excel.

The introductory chapter is historical and is satisfactorily brief. The relations of drinking water to disease consume Chapter II, and they are well and forcibly presented. Artificial purification of water occupies the third chapter, and its natural purification the fourth. Chapters on rain, ice, and snow, river and stream water, stored water, ground water, and deep-seated water follow. Chapters X and XI deal with the chemical and the bacteriological examinations of water respectively. Naturally, technicality pervades them, for it is not avoidable. The chapter on bacteriological examination is disappointing and to the physician at least can scarcely convey that sufficiency of information which the subject demands. In Chapter XII the quantity of per-capita daily supply is presented and Chapter XIII contains most important matter upon the action of water upon metals. Several interesting appendices conclude the work.

The book is made the more valuable by the able manner in which it is written. To be sure, the text is often interrupted by statistical and analytical tabulations, but they are required; moreover, they are well introduced and the easy style of the writer is sufficient to atone for the interruption. Illustrations are frequent throughout the book, and as a rule they are good.

*Lectures on Pharmacology for Practitioners and Students.* By Dr. C. BINZ, Director of the Pharmacological Institute in the University of Bonn. Translated from the Second German Edition by ARTHUR C. LATHAM, M. A., M. B. Oxon., M. A. Cantab., Radcliffe Traveling Fellow in the University of Oxford. Volume I. London: The New Sydenham Society, 1895. Pp. vi-389.

A CRITIC of Professor Binz's work in its earlier edition has said that it shows "that pharmacology is more interesting than many physicians and students imagine." The remark is most apt, and nothing has more forcibly impressed us in the reading than the contrast between this work and the typical *materia medica* of the English or the American writer. Tabulation, classification, division, and subdivision seem to exhaust the Anglo-Saxon ability in this field, and the substance or subject-matter wherewith the framework is provided is marasmic and cachectic. We do not in the least underestimate the importance of these works; for students they are suitable and essential, because the student must have his *materia medica* condensed and classified with care and even with minuteness if he is to acquire the knowledge of a subject so extensive. It is destructive to all pleasure in reading, however, this overclassification and tabulation, and for the practitioner it certainly is not essential. It

is in this uninterruptedness that Binz's work excels; from beginning to end, there is the smoothest and most agreeable continuity, and the conversational tone in which the author writes (the work is essentially the lectures delivered to his classes) makes the result pleasing in the highest degree. In fact, one reads this work not only with satisfaction and benefit but also with pleasure and entertainment. It would be well had more pharmacological writers this power to interest while they instruct, for the subject is one which is very badly written of. The subject matter calls for little comment, because it is that which the better works on pharmacology contain; it is the manner in which the facts are presented that is so unusual and so admirable.

*Medical Jurisprudence, Forensic Medicine, and Toxicology.* By R. A. WITTHAUS, A. M., M. D., Professor of Chemistry, Physics, and Hygiene in the University of the City of New York, etc., and TRACY C. BECKER, A. B., LL. B., Professor of Criminal Law and Medical Jurisprudence in the University of Buffalo. With the Collaboration of AUGUST BECKER, Esq.; CHARLES A. BOSTON, Esq.; the Hon. GOODWIN BROWN; W. N. BULLARD, M. D.; G. C. CAMERON, M. D.; J. CLIFTON EDGAR, M. D.; G. J. EDWARDS, Esq.; E. D. FISHER, M. D.; J. C. JOHNSON, M. D.; D. S. LAMB, M. D.; H. P. LOOMIS, M. D.; DAVID MURRAY, Esq.; W. B. OUTTEN, M. D.; ROSEWELL PARK, M. D.; W. T. PARKER, M. D.; J. PARMENTER, M. D.; the Hon. WILLIAM A. POSTE; IRVING C. ROSSE, M. D.; E. V. STODDARD, M. D.; EDWARD S. WOOD, M. D.; GEORGE WOOLSEY, M. D.; and J. H. WOODWARD, M. D. Volume III. New York: William Wood & Co., 1896. Pp. 697.

THE first article in the present volume is on the medico-legal relations of vision and audition and of injuries to the eye and ear, and is written by Dr. J. H. Woodward. The author reviews the methods of determining the degree of acuteness of vision, the several means of detecting simulated blindness, injuries of the orbit, the eyelids, and the eyeball, foreign bodies in the eyes, and sympathetic diseases of the eyes. Injuries of the ear are comprehensively reviewed, and the section affords satisfactory information in regard to ocular and aural troubles that may be of medico-legal interest.

Mr. David Murray and Mr. Guy J. Edwards, of the New York bar, are the joint authors of the section on the Medico-legal Aspect of Insurance, and they have successfully confined themselves to a consideration of those instances in which the practitioners of law and of medicine must co-operate to properly elucidate the questions involved in determining the nature and effect of the contract between the insurer and the insured.

Dr. Edward D. Fisher is the author of the section on the Medical Aspects of Insanity in its Relations to Medical Jurisprudence. In an able preface this author places stress on the necessity of regarding the mind as a whole, and not as if it consisted of independent faculties, and of the necessity of studying each case by itself. The mechanism of thought is briefly reviewed, insanity is defined, and its etiology, symptoms, and pathology are succinctly described. Krafft-Ebing's classification of the forms of insanity is used with some modifications, and the special forms of insanity are described with appropriate detail. The subject has been handled with a great deal of judgment, and the section is likely to meet the wants of both the lawyer and the physician.

One of the editors, Mr. Tracy C. Becker, is the author of the section on Mental Unsoundness in its Legal Relations, in which there is a comprehensive *résumé* of this important subject.

Mr. Goodwin Brown, in the section on the Care and Custody of Incompetent Persons and their Estates, gives a general view of the subject and a very useful and important digest of the statutes of all the States.

This volume sustains the good impression created by the preceding volumes, and the work is a safe guide for the student of this important branch of medicine.

*Transactions of the American Orthopædic Association.*  
Ninth Session, held in Chicago, September 17, 18, and 19, 1895. Volume VIII.

Upon the fly leaf of this book is the following: "The association does not officially indorse the opinions presented in the different papers published in the *Transactions*." It is not too high praise to say that the association could with pride indorse the greater number of the opinions therein expressed. Those papers devoted to the affections of the feet are, without exception, excellent. Dr. Whitman's article, presenting the mechanics of the human foot as a familiar machine, is the best treatise on the subject we have seen. His treatment of flat-foot, as herein expressed, is purely conservative, and the over-correction or twisting of the foot into the club-foot position is insisted on. The after-treatment—viz., by manipulation, massage, and proper exercises—is made, as he says, the most essential part. No less excellent, though less exhaustive, is the paper on Affections of the Arch of the Foot, by Dr. Lovett and Dr. Dane. A thing which is often not clearly understood, or else slightly—the difference between the so-called "flat-foot" and the foot with true pronation, with or without spasm and deformities—is here brought into prominence. The difference in treatment of the two essentially different affections is well expressed in both of the above-mentioned articles. We doubt if such remarkable results as are reported in Tendon Transplantation, by Dr. Goldthwait, will be often met with, as the operation becomes more popular. It seems remarkable that, as in Case I, the peronei muscles, longus and brevis, which are essentially not extensor muscles of the foot, should so completely fulfill that function as is shown in the photograph taken after the operation. Whether or no the patient had the power to raise himself and to support the weight of the body on his toes is not stated. The fact also that such a good result followed in a suppurating wound is unusual. In another case, where all the muscles of the foot were paralyzed except the three peronei, after suturing of the peroneus tertius and the extensor communis digitorum to the tendon of the paralyzed fibularis anticus, these comparatively weak muscles were made to perform the functions of this strong one. Here also we find "entire correction of the valgus and a very fair amount of flexion and extension."

In two cases of spasmodic wryneck, Dr. Halsted Myers has clearly given a fair trial to the use of coniun and atropine in large doses, in conjunction with the usual orthopædic appliances. In both was there an improvement in the spasm and in the movements of the head. To quote the author's words, "We can not ascribe the change to the coniun or to the atropine, since the effect produced by the latter seemed temporary in the doses in which it was possible to give it. The improve-

ment, therefore, must have been due to the direct or indirect action of the braces. They did not increase the muscular spasm, as has been claimed; on the contrary, they relieved the patients, I feel sure, from a great deal of unconscious nervous strain."

Even the most radical surgeons, we think, will hardly agree to the statement, in Dr. Plimpton's article on Excision of the Knee, that a few weeks or months are sufficient to determine whether the mechanical treatment is to be continued or excision resorted to. Here, as elsewhere in this article, the distinction between tuberculous joint disease in children and in adults is not given its proper weight. Again, we meet with the same grouping of these two essentially distinct classes of cases in the statement "all abscesses of joints, whether in children or adults, should be thoroughly drained." Sixty-five excisions of the knee joint without a death show certainly gratifying results. Ten minutes for the entire operation remains, we believe, "the record."

*Medical and Surgical Report of the Presbyterian Hospital in the City of New York.* Volume I. January, 1896.

We have so often protested against the senseless locking-up of valuable information in hospital records, and so often urged the publication of medical reports by our hospitals, as is done by English hospitals, that the action of the Presbyterian Hospital, as expressed in the preface of this volume, can not but give us satisfaction. No doubt an example so excellent will be followed by other hospitals, and when hospital boards in general have reached the magnanimity of the Presbyterian Hospital board of managers we shall have yearly a means of medical improvement and education which will be an aid not merely to the favored few but to all.

The report contains a multitude of things both interesting and important which have been furnished by the records of the Presbyterian Hospital and contributed by various of its medical officers. So much of excellence, indeed, is herein presented that one is almost at a loss to cite those things which are noteworthy in particular. The articles which have given us special pleasure, however, are those upon caisson disease, tetany, tumors of the kidney, cancer of the cæcum in a patient, aged twenty-four, with symptoms resembling those of acute appendicitis, and subdiaphragmatic abscess simulating empyema. A tabulated report of the medical division of the hospital is followed by one of the surgical division, and this by a list of operations performed. The volume concludes with a chapter devoted to the preparation of dressings and surgical appliances as practised in the operating pavilion.

We heartily congratulate the hospital upon its report and the editors and contributors upon the excellence of their work. We congratulate the profession, too, that hereafter one of our hospitals at least will provide us with a report which will give us medical knowledge rather than statistics of sex, race, religious belief, color, and board-paying ability alone. In conclusion, we desire to quote from the preface of this report, that the sentiments therein expressed may be the more widely known. "The management of the Presbyterian Hospital issues this, its first *Medical and Surgical Report*, believing that a permanent record should be made of the valuable and interesting scientific material that is found in the hospital. The first duty of a hospital is to care for the sick. Its next duty is to advance in every possible way the knowl-

edge of the nature and treatment of disease. It is proposed that this shall be the first of a series of similar reports to be published annually."

*How to Feed Children.* A Manual for Mothers, Nurses, and Physicians. By LOUISE E. HOGAN. Philadelphia: J. B. Lippincott Company, 1896. Pp. 5 to 236. [Price, \$1.]

THE scope and object of this little book are well presented in its preface, where we read "It is also hoped that the book will meet the requirements of practitioners, who rarely have the time to direct in detail the management of children's diet. It is not the intention of the author to advise where a physician is needed, but rather to suggest to the mother or nurse when he should be sent for, and how he may be aided in his efforts by the exercise of intelligence and judgment in the selection and preparation of foods indicated for various ages and varying conditions of illness and convalescence."

The writer adheres well to her plan as outlined, and the excellence of the work is largely due to that fact. Clearness and simplicity mark the work throughout and render it an agreeable contrast to those productions whose subject is the same and whose intent perhaps is good, but whose result is to confuse and to alarm, because they seek to teach the mother things which she is not competent to understand. In no place does the writer suggest independence of the physician; on the contrary, she constantly refrains from elaborating her teaching, lest she encroach upon what is more wisely referred to him, and in so doing work a harm. Her teaching is complementary of that of the physician, and nobody who reads the book can fail to observe how well her object is attained. That the work is a compilation is true, but it is compiled from sources of great excellence and the selection is well made. We wish in particular to commend the dietaries and menus, which will certainly be of assistance to those who have the care of children. The recipes, too, are excellent. We feel sure that the book will be of much service to those for whose aid it was written, for it is both ample and comprehensible.

#### BOOKS, ETC., RECEIVED.

*Practical Points in Nursing.* For Nurses in Private Practice. With an Appendix containing Rules for Feeding the Sick; Recipes for Invalid Foods and Beverages; Weights and Measures; Dose List; and a Full Glossary of Medical Terms and Nursing Treatment. By Emily A. M. Stoney, Superintendent of the Training School for Nurses, Carney Hospital, South Boston, Mass. Illustrated with Seventy-three Engravings in the Text and Nine Colored and Half-tone Plates. Philadelphia: W. B. Saunders, 1896. Pp. 12 to 456. [Price, \$1.75.]

*A Manual of Obstetrics.* By W. A. Newman Dorland, A. M., M. D., Assistant Demonstrator of Obstetrics, University of Pennsylvania, etc. With One Hundred and Sixty-three Illustrations in the Text and Six Full-page Plates. Philadelphia: W. B. Saunders, 1896. Pp. 7 to 760. [Price, \$2.50.]

*Clinical Diagnosis.* A Practical Handbook of Chemical and Microscopical Methods. By W. G. Aitchison Robertson, M. D., D. Sc., F. R. C. P. E., F. R. S. E. London: The Scientific Press, Limited, 1896. Pp. 366. [Price, 6s.]

*Familiar Trees and their Leaves.* Described and Illustrated by F. Schuyler Mathews, Author of *Familiar*

*Flowers of Field and Garden*, etc. With over Two Hundred Drawings by the Author, and an Introduction by Professor L. H. Bailey, of Cornell University. New York: D. Appleton & Co., 1896. Pp. x-1 to 318. [Price, \$1.75.]

*Maladies des voies urinaires. Séméiologie.* Par P. Bazy, chirurgien de l'Hôpital Tenon, etc. Paris: Masson et Cie., 1896. Pp. 5 to 212. [*Encyclopédie scientifique des aide-mémoire.*]

*L'Ergotisme. Ignis sacer. Ignis sancti Antonii.* Par le Dr. Edvard Ehlers, de Copenhague. Paris: Masson et Cie., 1896. Pp. 7 to 167. [*Encyclopédie scientifique des aide-mémoire.*]

#### Miscellany.

**The Sting of Bees, Wasps, and Hornets.**—The *Indian Lancet* for June 1st contains an interesting article on this subject by Surgeon-Major R. E. Wrafter, of the Bengal Medical Service, of which the following is an abstract:

The stings of bees, wasps, and hornets are the result of punctured and at the same time poisoned wounds, not made by the insect to obtain food, but in anger and for its own defense. Bees are not always on the alert to use their stings without reason, nor are they in the habit of attacking in concert. As a general rule, they sting only when they are irritated, hurt, or protecting their stores. Some stocks will be found much less excitable than others, the former being often those which are near a road or pathway; they also differ in excitability according to the season. During the rainy season in the plains the bees appear to be less active and less prone to sting than during the hot summer months; during the winter, also, when the temperature sinks to zero, they are inactive.

Into these wounds, which are made with a sharp, hollow dart at the extremity of the body, poison, which is secreted in twisted tubes and poured into a little bag, specially formed as a reservoir, is thrown by the sting dart which protrudes from between a sheath formed by two side plates at the end of the insect's body. The sting of a bee is barbed at the end, and is, consequently, always left in the wound; that of a wasp is pointed only, so that they can sting more than once, which a bee can not do. The agonizing pain which follows the sting of a bee, wasp, or hornet, more especially that of the latter, is probably, for the time, as great as any to which we are liable. The throbbing is intense, and if the skin is thin and loosely connected with the parts beneath, a swelling quickly rises, the skin becomes tight, shiny, and almost transparent, as if air or water (œdema) had been forced beneath it. This swelling comes on very rapidly and spreads very quickly, so that a sting on the finger may cause the whole hand to swell, and the swelling may even extend along the arm; if the eyelid is stung, the eye is quickly closed, or, if the lip, it becomes twice or thrice its usual size. Not infrequently, if the insect has been irritated, it stings with such good will that it leaves a great part, if not the whole, of its stinging organ sticking like a dart in the wound, and though it escapes, it thereby destroys itself. The bee on inserting its sting can not withdraw it excepting by gyrating round to unscrew it, hence the sting is usually left in the flesh and the poison bag is torn out of

the bee and left behind. The hornet's sting is the most severe, and the bee's the least. The wasp, an insect allied to the hornet, is capable of stinging severely also. To be stung by a bee is admittedly a painful accident, but if a person is stung by many bees, he suffers severely, and there are instances on record in which death has resulted from multiple injuries of this kind. No very careful investigation of these cases appears ever to have been made, and the circumstances have generally been such that even a skilled scientific observer would have found it difficult to note the phenomena accurately, but it would seem that so large a dose of insect poison acts very much like snake-venom, and that the main cause of death is shock to the nervous system. The immediate dangers from these injuries are shock and septicæmia, the remote dangers are erysipelas, phlebitis, and pyæmia. The venom of the bee, according to Fontana, bears a close resemblance to that of the viper. It has been observed that the pain of the stings of venomous insects like the bee depends less upon the introduction of the sting into the part than upon that of the venomous fluid.

Professor Dumeril's experiments tend to prove that, when the little poison bag, situated at the base of the sting, has been cut off, a wound with the sting produces no pain. The poison flows from the vesicle through the sting at the instant when this passes into the flesh. The active principle of the venomous fluid is said to be formic acid. When applied to mucous surfaces, even to the conjunctiva, it causes no disagreeable sensation, but when it is introduced into the skin by means of a hypodermic needle it immediately excites very acute pain.

The treatment of all these cases is, in its general principles, the same; local irritation is to be soothed, and if constitutional symptoms occur, they are to be combated by appropriate remedial measures. One or two stings from these insects are not usually considered of serious importance, but when, as sometimes happens, a swarm of wasps or bees attack a person, the number of stings inflicted may induce severe nervous depression, vomiting, and local pain. Or in delicate persons, or children, several stings may cause serious constitutional disturbance. Under such circumstances a stimulant will probably be first required, after which the sting or stings should be removed with a fine-pointed forceps, or, if they are too deep to be laid hold of, the hollow tube of a small key may be placed over the injured part, so that the puncture shall be in the middle, and by pressing it firmly down the skin be caused to rise in the hollow, when the sting will probably start out, or a watery fluid will escape, carrying with it some of the venom. This precaution will prevent the irritating poison from spreading. If a lens is at hand, it will be well to examine each wound, when perhaps the sting may be seen, and it may be extracted with the forceps. Then local applications may be applied.

As the poison is mostly of an acid nature, the application of a little alkali, such as ammonia water, to the injured part, will produce immediate relief. Sodium bicarbonate dissolved in a little water, or liquor potassæ will answer very well, and the application of sweet oil or glycerin, the juice of a plantain leaf, or the pulp of a raw onion has long held a prominent place in domestic materia medica. The pain of these venomous stings is often greatly relieved by the constant application of a piece of linen moistened with pure vinegar or tincture of calendula. The oil of lobelia is said to give prompt relief. A solution of lead acetate is effectual, also dilute carbolic acid. A poultice of powdered ipecac is largely

employed in Australia in cases of venomous stings. Of all these topical remedies alkaline preparations (ammonia or soda) certainly appear to be the most serviceable. The popular remedy of the "blue bag" (which is used in washing) moistened with water is probably useful for this reason. Alkalies seem to neutralize the poison. Should there be much swelling or inflammation, foment the part with hot water.

When the mouth or throat is the part stung, serious symptoms may manifest themselves in œdema and swelling which impedes respiration. When this happens, warm flannels should be applied to the neck, and subsequently a warm poultice of linseed meal, frequently renewed, generally affords relief.

**The Preparations of Strophanthus.**—The July number of the *American Journal of Pharmacy* contains a report of the research committee on pharmacodynamics in which Dr. Horatio C. Wood and Dr. William S. Carter state that the United States Pharmacopœia of 1890 recognizes only one preparation of this important drug—namely, the tincture. It is, however, they think, desirable to give strophanthus with other drugs in pill form, and the object of the research committee was to test the activity of the best commercial strophanthin and also of an extract. In order to determine whether the extract would be an effective preparation, they undertook a series of experiments with the drug. The extract was made by Dr. Charles Rice. A detailed account of the experiments is given, in each of which a solution of the extract, in the proportion of fifteen grains to a thousand cubic centimetres of water, was injected into the jugular vein of dogs.

The authors state that an examination of these experiments will show that the extract of strophanthus is an active preparation. The fact of the great percentage of rise in the last experiment, when the spinal cord had been previously cut and the vasomotor system paralyzed, is, they think, very interesting as an evidence of the little action which this drug has upon the vasomotor centres, as compared with what it has upon the heart and vessel walls. A comparison of these experiments will also show the great difficulty there is in testing drugs by comparative experiments upon the lower animals, the amount of rise in individual cases produced by the injection being entirely out of proportion to the relation between the dose given and the weight of the animal.

In the series of experiments with commercial strophanthin, the solution used was made by dissolving fifteen grains of the drug in a hundred cubic centimetres of water, and it was injected directly into the jugular vein. The results of these experiments are, the authors think, sufficient to show that the commercial strophanthin, as put upon the market by manufacturers of the first class, is an extremely active substance.

As long ago as 1888, Rothziegel and Koralzowski reported the results of the use of strophanthin in forty-four cases of disease. They state that the influence of very small doses, 0.0002 to 0.0003 gramme, is distinctly perceptible in an increase of the force of the pulse in from five to ten minutes; but that usually in cardiac cases the disappearance of the irregularity of the heart's action was not perceived until the second or third day of treatment; that when there was dyspœnia from cardiac disease, the difficulty in breathing disappeared very rapidly. No local irritation was, in their experience, produced by the hypodermic injection of as much as five decimilli-

grammes of the strophanthin. They ordinarily gave from one to three milligrammes in the twenty-four hours; in one case they gave five milligrammes for eight days, without any bad results. In two cases, however, the daily use of three milligrammes for two weeks caused reduction of the pulse-rate to forty-eight a minute, without any other accompanying symptoms. They reached the conclusion that the strophanthin was a good substitute for the tincture of strophanthus.

Dr. Wood and Dr. Carter state that the records of their experiments show that the activity of the strophanthin itself was much more marked in raising the arterial pressure than that of the extract, so that confirmation is afforded of the conclusion of Rothziegel and Koralewski—that strophanthin is a superior preparation of the drug.

They believe, therefore, that the *Pharmacopœia* should recognize the active principle of strophanthus, and give appropriate tests for its purity.

**The Northern Tri-State Medical Association.**—At the regular annual meeting which is to be held in Angola, Ind., on July 21st, the following papers will be read: The Management of Vesicalculus, by Dr. Frederick J. Hodges, of Anderson, Ind.; The Cause and Treatment of Color Blindness, by Dr. F. C. Mayson, of Hillsdale, Mich.; Purpura Hæmorrhagica, by Dr. Frank M. Gier, of Hillsdale, Mich.; Modern Brain Operations, by Dr. Allen de Vilbiss, of Toledo; Salicylate of Sodium in Septic Conditions, by Dr. H. O. Pantzer, of Indianapolis; Some Considerations on the Treatment of Acute Otitis Media, by Dr. A. E. Bulson, of Fort Wayne, Ind.; Embryonic Miscarriage, by Dr. J. R. Dodge, of Hudson, Mich.; Asepsis and Antisepsis: Which, or Both? by Dr. J. B. Greene, of Mishawaka, Ind.; Aseptic Technics in Pelvic and Abdominal Operations Outside of Hospitals, by Dr. C. N. Smith, of Toledo; Conservative Surgery in Tuberculosis of the Testicle, by Dr. J. E. Murphy, of Chicago; The Differential Diagnosis of Insanity, by Dr. C. B. Burr, of Flint, Mich.; Diffuse Cellulitis of the Hand and Forearm, by Dr. W. W. Brand, of Toledo; A Case of Brain Tumor, with an Exhibition of Specimens, by Dr. G. W. McCaskey, of Fort Wayne, Ind.; Obstruction of the Bowels, by Dr. Hal C. Wyman, of Detroit; The Diagnosis of Typhoid Fever, by Dr. W. C. Chapman, of Toledo; Growths of the Rectum, with a Report of Cases, by Dr. H. O. Walker, of Detroit; and The Need of Abdominal Section as an Aid to the General Practitioner in the Diagnosis of Obscure Abdominal Troubles, by Dr. J. H. Carstens, of Detroit.

**The Injection of Saline Fluid into the Axillary Cellular Tissue in Cases of Severe Hæmorrhage.**—The *Lancet* for June 27th contains an account of a case which came under Mr. Arthur Dodd's observation in which he made use of this method of treatment. The author was sent for to attend a multipara in whom excessive hæmorrhage had taken place during the preceding two hours without, apparently, any progress having been made in the labor. He found the patient had lost an enormous quantity of blood and was in a dangerous condition, being blanched and pulseless, and the pains, which had been going on regularly for several hours previously, had entirely left her. Upon examination he found the os only partially dilated and the membranes protruding, but no presentation detectable. He ruptured the membranes, and a large quantity of liquor amni escaped, and he found that the cause of the hæmorrhage was right partial placenta prævia. The patient was in an exceed-

ingly critical condition; there was vomiting, a cold, clammy perspiration, and sighing respirations; the bowels acted involuntarily, and she was pulseless, semiconscious, and apparently rapidly sinking. Two subcutaneous injections of ether were given without the slightest improvement. Transfusion was then performed, about a pint of liquid being used, although, says Mr. Dodd, the case was considered hopeless.

However, after a very brief interval there were indications of slight improvement and a very feeble pulse was detectable at the radials. During the next two hours small quantities of warm milk and brandy were given at frequent intervals. After that time there were decided symptoms of rallying and benefit from the transfusion, and the pains returned. By examination a vertex presentation could be made out and one one-hundredth of a grain of ergotine was injected and delivery accomplished with the forceps.

It may be interesting to note, says the author, that the child, a girl, was stillborn and very large, weighing eight pounds and three quarters and measuring twenty-one inches and a half in length. It was in a state of well-marked rigor mortis, the stiffness of the limbs and body adding considerably to the difficulty of completing delivery, which was accomplished at 12.45 A.M. The movements of the child had been last felt at 6 P.M. The placenta was easily removed, and the position of the part whence the hæmorrhage occurred found well marked on its border. The patient made an uninterrupted recovery, assisted by taking iron in the form of Bland's pills (bi-palatinoids) for several weeks.

The results of the transfusion were rapid absorption of the saline fluid (hardly any swelling remaining at the end of two hours) and decided and rapid improvement of the urgent symptoms, thus enabling the patient to take minute quantities of nourishment; and its advantages are the quick, ready, and easy application of the method, which could be managed at any time single-handed.

The credit of this method of treatment, says Mr. Dodd, is due to Mr. Thomas H. Morse, of Norwich, and it was owing to his suggestions some time ago that he became aware of it. The instrument used is a very slight modification of Mr. Arbuthnot Lane's transfusion apparatus, made by Messrs. Down Brothers, the only difference being that a sharp-pointed needle of a little stouter make is required instead of the blunt one used for introduction into a vein, and the ordinary saline solution is used—i. e., a teaspoonful of common salt to the pint of boiled water cooled down to the proper temperature (100° F.). Having fitted the needle, tube, and syringe together, fill the latter with the solution, then force the steel point of the needle through the skin of the axilla deep enough to move freely into the cellular tissue, and slowly and gently force the fluid into the cellular tissue. Refill the syringe and proceed again until a pint or more has been used.

**The Laws Governing Medical Practice in Pennsylvania.**—The July number of the *University Medical Magazine* contains an article on this subject in which the following synopsis of the law of 1893 is given by Dr. W. D. Hamaker, of Meadville, Pa., who states that there is a lack of knowledge among professional men in regard to this law:

The law of 1893 has been in force since June, 1894, and has for its main object the examination of all who wish to begin the practice of medicine and surgery in Pennsylvania.

This law establishes a medical council, composed of the lieutenant governor, the attorney general, the secretary of internal affairs, the superintendent of public instruction, the president of the State board of health, and the presidents of the three State boards of medical examiners.

The council issues all licenses to practise, and all candidates for examination and license write to the secretary of the council at Harrisburg, presenting their credentials, and receive permission from him to appear before one of the State boards of examiners.

The applicant must present a written application for license, inclosing a fee of twenty-five dollars, together with satisfactory proof that he is over twenty-one years old, is of good moral character, has obtained a competent common school education, has a diploma from a legally incorporated medical college, and has studied medicine for four years, including three regular courses of lectures in different years in a medical college.

The council then issues an order for the applicant to appear before the examining board which he may elect. If the applicant fails to pass, he can appear at any future examination, and for his second examination does not pay an additional fee if he takes it within two years. He may undergo an examination every six months if he wishes.

Physicians licensed by boards of other States are licensed in Pennsylvania, on filing their licenses, duly certified, together with proper affidavits showing the standards of the other States to be equal to that of Pennsylvania.

When the applicant receives his order from the medical council he appears before one of the three State examining boards at the June or the December meeting. The three examining boards are appointed by the governor from the certified lists of members of the Medical Society of the State of Pennsylvania, the Homeopathic State Society, and the Eclectic State Society. Each board consists of seven members, and each member serves for three years, and must be a registered physician in good standing, and shall have practised at least ten years.

Said boards are authorized to take testimony in all matters within their jurisdiction, and the presiding officers of the boards or of any committees may issue subpoenas and administer oaths to witnesses.

Two or more examinations may be held each year (time and place determined by the board). The examinations are in anatomy, physiology, hygiene, chemistry, surgery, obstetrics, pathology, diagnosis, therapeutics, practice of medicine, and materia medica; the questions in therapeutics, practice, and materia medica shall be in harmony with the teachings of the candidate's school of practice. The examinations are in writing. The papers, after having been examined and marked by the boards, are placed on file at Harrisburg for five years, subject to public inspection.

After having received a license to practise the candidate shall exhibit the license to the prothonotary of the county in which he or she desires to practise, whereupon he or she, upon the payment of one dollar, shall be entitled to be registered. A violation of any of the provisions of this act shall be punished by a fine of not more than five hundred dollars for each offense.

Medical officers of the army and navy, marine hospital, and railroad relief departments, internes of hospitals, dentists, druggists, and instrument-makers are exempted.

Physicians of other States can come into the State in consultation with Pennsylvania physicians, and physicians just across the line in other States whose practice extends over into Pennsylvania, can attend their patients, but must not have an office or place to meet patients in this State.

Practitioners duly registered before March 1, 1894, shall not be interfered with, and one such registry shall be sufficient warrant to practise medicine and surgery in any county in this commonwealth.

The law of 1881 was practically repealed by the law of 1893, but part of the law of 1877 is still in force, according to the opinion of Attorney-General McCormick, and according to the decision of the Supreme Court in the case carried up from Bradford County in 1892, in which the court held that the law of 1881 did not entirely repeal the law of 1877. It is not hard to tell what the decision of the court would be if a similar case were carried up under the law of 1893, as this law does not repeal the law of 1877 any more than the law of 1881 did. The law of 1877 relates in part to itinerant or transient physicians, and requires that any physician (otherwise legally qualified) who opens a transient office within the commonwealth or by hand-bill or other form of written or printed advertisement, assigning such transient office or other place to persons seeking medical or surgical advice, or prescribing or itinerating from place to place or from house to house, and proposing to cure any person sick or afflicted by the use of medicine, means, or agency whatsoever, for valuable consideration, shall take out a license from the clerk of courts of the county in which he wishes to practise, for one year, for which he shall pay a license fee of fifty dollars to the county treasurer and a registration fee of five dollars to the clerk of courts. The fine for violation of this law is from two hundred to four hundred dollars.

This law has excited some interest lately, from the fact that a number of physicians (itinerants), who were registered in some county under the act of 1881, have maintained the right to practise as itinerants under section 15 of the law of 1893, which says that one such registry (i. e., under the law of 1881) shall be sufficient warrant to practise medicine and surgery in any county in this commonwealth.

It is clearly established, then, that registration under act of 1881 ceased with the adoption of the law of 1893; that a licensee under the act of 1893 must register in every county in which he may practise; that the physician who registered under act of 1881 is not required to register in every county in which he may practise, and that in addition to being registered under act of 1881 or 1893, a sojourner or itinerant practitioner must comply with the law of 1877. Under the law of 1877 it is not allowable for a physician to open a temporary or transient office even in his own county without taking out an itinerant's license.

**An Interesting Case of Fœtus Inclusus.**—The *Lyon médical* for June 4th cites the following case from the *Journal de médecine de Paris* for May 31st: The patient, a student seventeen years old, received a slight blow on the upper part of the abdomen. Up to this time he had never felt any troublesome symptoms, but after the blow the abdomen increased in size day by day until at the end of two years the swelling had attained the size of a child's head. An operation was then deemed necessary, and it was performed by M. Mayde and M. Sanger, who found, on opening the abdomen, a fœtus which

measured forty-four centimetres. It appeared to be about five months old. The head was rather badly deformed, but the limbs were almost regular in shape. The skin was somewhat retracted and thick. The hairy system was regularly localized and the hair on the head measured not less than thirty centimetres in length. The tumor was situated under the peritoneum not far from the liver, between the mesenteric folds, and contained, besides the fetus, which was of the female sex, an abundant yellow liquid of a gelatinous consistence. The patient died twenty-four hours after the operation.

**Lactation Atrophy of the Uterus.**—In an article on this subject published in the July number of the *American Journal of the Medical Sciences*, Dr. Hiram N. Vineberg, of New York, remarks that it is singular that in this country the subject of lactation atrophy of the uterus has received absolutely no attention. It is even more singular, he says, that the condition seems entirely to have escaped observation. He calls attention to that form of atrophy which accompanies lactation, with or without amenorrhœa, in which the reduction in size is temporary only, the return to the normal size being in some cases dependent upon the cessation of lactation, in others, again, regeneration of the uterine tissue occurring while lactation is going on.

Two varieties of lactation atrophy are recognized, says Dr. Vineberg, the eccentric and the concentric. The term eccentric atrophy is applied to a uterus whose cavity is of the same depth as the ordinary parous organ, but whose walls are appreciably thinner and more flaccid. When the organ is decidedly smaller in all its dimensions, when the cavity from the fundus to the border of the anterior lip of the cervix does not measure more than from 4.5 cm. to 6.5 cm., and the uterine walls are thinner than normal, though they may not be flaccid, the term concentric atrophy is employed. Concentric atrophy may, therefore, be considered as only a higher grade of the eccentric variety. As might be expected, various grades between the two varieties are met with. The terms are merely arbitrary, but serve the useful purpose of concisely designating the degree of atrophy. It is not uncommon to meet with an eccentric atrophy which under continued lactation becomes concentric.

According to the author's observations, the process affects the body and the cervix equally. In some of his cases, he says, it is true, the cervix was much larger in proportion than the body, but it seemed to him that the enlargement was due to a pathological lesion, such as a bad laceration or an accompanying endocervicitis. These observations harmonize with those of Engstroem and Mueller. Thorn, however, states that in his cases the cervix remained unaffected, and that it showed atrophy only in the very highest grades when the external genitalia and the abdominal walls might also become involved in the process. Gottschalk drew similar conclusions from his cases.

Whether or not, says Dr. Vineberg, puerperal atrophy apart from lactation frequently occurs must be left to future investigation. To its non-occurrence, he thinks, may be attributed many of the gynecological cases seen in private practice. The history which every one will readily recognize is usually as follows: The patient has had a normal labor and normal puerperium. At the second, third, or fourth week, the custom varying in accordance with the social standing of the parturient, the attendant physician has dismissed himself, saying that everything was all right. The woman says that she

felt well for some months after labor, but that for the past few months she has suffered from leucorrhœa and a sense of weight in the lower part of the abdomen, and has been tired on the least exertion. There may be and there usually is backache, with more or less of a dull pain extending down both thighs. On examination, one finds redundant vaginal walls, a large uterus of flabby consistence, some leucorrhœal discharge, and abnormal mobility of the uterus owing to a lax condition of the pelvic tissues. The striking feature of these cases is the gradual onset; the patient can scarcely tell just when she began to have symptoms. This picture is most frequently met with among the better classes, in whom lactation is the exception rather than the rule.

Dr. Vineberg states that it is his firm conviction that this condition is the outcome of imperfect involution and could readily be avoided if the attendant physician kept his patient under observation for at least three months after the puerperium. It is his custom at his last visit to request the parturient to present herself at his office for examination once a week or once every two weeks until at least the twelfth puerperal week. By observing this rule he has frequently been able to avert, by timely recognition, the ill consequences accompanying deficient involution.

It naturally follows, he continues, that there is nothing to be said on the treatment of lactation atrophy. The nursing woman should be kept under constant surveillance, an effort should be made to keep up good nutrition, and the period of lactation should not be allowed to be prolonged beyond a reasonable period.

Dr. Vineberg draws the following conclusions: 1. Modern researches tend to prove that post-puerperal involution consists chiefly in a retraction and contraction of the individual muscle fibres whereby the whole uterus is reduced in size.

2. When involution goes on to its full completion the uterus is reduced to a size smaller than that of the non-parous organ.

3. This condition of complete involution is known as post-puerperal "hyperinvolution." It is principally seen in nursing women, and from this circumstance has received the cognomen of *lactation atrophy*.

4. The so-called lactation atrophy is a normal and desirable condition. It is temporary in its duration, but very rarely, under unfavorable circumstances, may become permanent.

5. When the parturient is unable to perform the function of lactation it is the duty of the physician to endeavor to bring about "hyperinvolution" by other means at his disposal. An observance of this course will prevent many a woman from developing a host of gynecological affections which frequently result from imperfect involution.

**The Physiological and Therapeutical Action of the Blister.**—In the issue of the *Journal* for June 20th we published an abstract of an article by M. Huchard on The Rise and Fall of the Use of the Blister, which appeared in the *Journal des praticiens* for May 30th, in which he alluded to the objections that had been made against the employment of the blister and the dangers to which it might give rise. In the same journal for June 6th M. Ferrand contributes a paper which seems to be in the nature of an answer to M. Huchard.

The first question to be considered, he says, is, What is the rôle of the fly blister in infectious diseases? It has been stated that it should be banished from the

treatment of these diseases because it adds a new toxic agent to those which already exist in the organism. The blister is not necessarily toxic. It is a therapeutic agent the physiological properties of which may be employed without exposing the subject to any toxic influence. It is a less dangerous agent, for instance, than the majority of the medicaments in the aromatic series, which easily become dangerous, but for which they are not to be condemned.

The fly blister is a remedy that may render good service, because it is an eliminator and a drastic when it is judiciously employed; it is also a general excitant which influences primarily the circulation and secondarily the nervous system, and in all cases it is capable of arousing the activity of one or the other of these systems when it has declined, as, for example, in infectious diseases, where it often falls so low that it sometimes seems paralyzed. Furthermore, it may exert an antiseptic influence in infectious diseases, as may be proved by the following, says the author: According to the researches of Devoto, which were based upon the works of Lucatello and Antonini, and also according to the studies of Valvassori and Peroni, the fly blister causes the multiplication of the leucocytes, that is, of those elements which attack the infectious microbes in order to accomplish their destruction and annul their deadly influence. The same authors have also demonstrated that the blister notably increases the bactericidal power of the serum. It may be concluded then, he says, that the blister is an eliminator, a neuro-vascular excitant, and an antiseptic.

Concerning the question which was raised in regard to the dangers that the blister might give rise to in the urinary tract, M. Ferrand responds by showing that authors have successfully employed this method in the treatment of diseases of the kidneys and in certain cases of albuminuria. He cites Cruveilhier and Lancereaux as having employed this treatment advantageously; Rayer also reported five cases in which the treatment was successfully employed. He cites many others to prove that a treatment which may be useful in diseases of the kidneys should not be proscribed under the pretext that in certain well-known and exceptional conditions it may give rise to danger.

M. Legendre, continues M. Ferrand, stated that when this treatment was once established in thoracic affections it prevented all other active treatment. What, he asks, are these therapeutic means that the blister renders impossible? Certainly not cupping, plasters, or even baths.

Regarding the renal complications referred to by M. Huchard, says M. Ferrand, there are patients whose renal susceptibilities are great and may be aroused by any excitant. How many patients there are who present symptoms of acute uræmia and even of uræmic encephalopathy from various causes, with which the blister has nothing to do. There are others in whom the skin can not bear the contact of diachylon without erysipelas manifesting itself—those in whom the use of antipyrine gives rise to a violent urticaria; those who become intoxicated with an insignificant dose of opium or of potassium iodide, etc.—and yet we do not proscribe these agents because of the intolerance shown for them in exceptional cases.

To sum up the whole matter, continues M. Ferrand, the blister is a therapeutic agent which must not be abused in its employment; nevertheless, it is a valuable agent because it possesses a well-defined physiological action as follows: On the nervous system, which Brown-Sequard described as being either dynamogenic or in-

hibitory, according to the conditions in each case; a vascular action, producing either anæmia or congestion, according to the time and the distance at which it is observed; a nutritive action, producing atrophy and consequently resolution. Its action is therefore incontestably revulsive, and it is, furthermore, a nervous and vascular tonic.

**The Importance of a Thorough History in Surgical Cases.**—Dr. A. Hille made this the subject of his Gröbsswald inaugural dissertation, in 1895. He cites a number of cases showing the diagnostic importance of the patient's previous history, among them one in which, in the course of a radical operation for scrotal hernia, Helfferich found a diverticulum from the bladder in the hernial sac. It was recognized by its muscular contractions, and so escaped injury. It was subsequently ascertained from the patient that when he held his urine for a long time he had had pain on urinating, radiating to the hernia, and that by pressing on the hernia he could mitigate the pain. It is particularly in recent injuries of joints, says Hille, that the past history is of importance; sometimes it may be ascertained that the joint has been injured long before, perhaps in childhood, in such a manner as to make the diagnosis very difficult if the old injury is unknown or unhealed.

Dr. C. Lauenstein, of Hamburg, who contributes a summary of Hille's dissertation to the *Centralblatt für Chirurgie* for June 27th, refers to Helfferich's advice to young surgeons to make as much use as possible of the history of the patient, and remarks that the previous history is of the utmost value in rare fractures and dislocations, but he is careful to add that it must be most rigorously compared with what is detected by physical examination.

**The Results of Injections of Erysipelas Toxines upon Malignant Growths.**—At a recent meeting of the New York Surgical Society, a report of which is published in the July number of the *Annals of Surgery*, Dr. L. A. Stimson, Dr. A. G. Gerster, and Dr. B. F. Curtis submitted the following report upon the use of erysipelas toxines in the treatment of malignant disease:

"Both before and since our appointment as a committee, we have been able to observe, individually and together, a considerable number of cases treated by this means, and in no case have we found any amelioration which held out a prospect of ultimate cure. We have, on the contrary, observed in some cases that the rate of growth of the disease was much more rapid during the treatment. The treatment also imposes a very severe tax upon the strength of the patient, and apparently hastens the cachexia in most cases.

"We believe that in the instances of apparent cure or marked improvement the correctness of the diagnosis is open to doubt.

"We therefore submit:

"1. That the danger to the patient from this treatment is great.

"2. Moreover, that the alleged successes are so few and doubtful in character that the most that can be fairly alleged for the treatment by toxines is that it may offer a very slight chance of amelioration.

"3. That valuable time has often been lost in operable cases by postponing operation for the sake of giving the method of treatment a trial.

"4. Finally, and most important, that if the method is to be resorted to at all, it should be confined to the absolutely inoperable cases."

## Original Communications.

### HYDROCEPHALIC IDIOCY.

By FREDERICK PETERSON, M. D.,

CLINICAL PROFESSOR OF INSANITY,  
WOMAN'S MEDICAL COLLEGE OF THE NEW YORK INFIRMARY;  
CHIEF OF CLINIC, NERVOUS DEPARTMENT,  
COLLEGE OF PHYSICIANS AND SURGEONS, NEW YORK;  
CONSULTING NEUROLOGIST TO THE RANDALL'S ISLAND HOSPITAL FOR IDIOTS.

HYDROCEPHALUS is a not infrequent cause of idiocy. Producing, as it does, pressure upon the brain substance, with consequent impairment of function, either from the compression alone or from actual destruction by atrophy of the tissues, we note among the multiform results of hydrocephalus, enfeeblement of the mind, varying from simple feeble mindedness to complete idiocy, as well as paralysis, convulsions, blindness, and the like.

Bourneville distinguishes three classes of hydrocephalic idiocy, viz.:

1. Simple or common hydrocephalus.
2. Scapho-hydrocephalus.
3. Symptomatic hydrocephalus.

The first class he again divides into two groups: (1) Simple hydrocephalus without malformation of the brain, and (2) simple hydrocephalus complicated with malformations or lesions, such as absence of the corpus callosum or of the cerebellum. This latter variety may include either the ventricles alone, or, at the same time, the arachnoid cavity, in which case it may be at times encysted in the arachnoid cavity.

To the writer this classification is unnecessarily complex. For instance, the second group is distinguished merely because the head has a scaphoid shape. But, since in simple hydrocephalus there may be several varieties of cranial conformation, as will be noted later, it scarcely seems justifiable to make of scaphocephalus a distinct type. The writer would, therefore, divide hydrocephalus into two classes only, viz.:

- I. Primary hydrocephalus.
- II. Secondary hydrocephalus.

To the first group belong the cases of ordinary hydrocephalus of unknown pathology. In the second class are comprised such cases of hydrocephalus as are secondary to meningo-encephalitis or encephalic tumors.

The condition we are more immediately concerned with is primary hydrocephalus, known variously as chronic hydrocephalus, hydrocephalus internus, and "water on the brain." It consists of an excessive accumulation of fluid in the ventricles of the brain, which expands the cavities to a greater or less degree, sometimes enormously, thus thinning the brain substance surrounding the fluid, and increasing the size of the head by separation and spreading out of the bones. The disorder is congenital or acquired. If acquired in childhood there is enormous development of the cranium. If acquired later in life the expansion of the skull may

be slight or imperceptible. Where defect or malformation of the brain coexists the fluid may be found not only in the ventricular cavities, but also exterior to the brain, constituting the condition of hydrocephalic anencephalus. Occasionally spina bifida coexists.

**ÆTIOLOGY.**—In all cases of hydrocephalus a neuropathic basis is found. Direct heredity is rare, though it is sometimes noted. Bourneville mentions a mother and two children affected with hydrocephalus. We discover commonly among the ascendants various neuroses or psychoses. Alcoholism in the parents is particularly frequent. In twenty-two cases reported by Bourneville, sixteen showed alcoholism in the antecedents, two abstinence, two no alcoholic history, and in two no history could be obtained. Insanity, imbecility, epilepsy, and migraine seem to be especially common conditions among ascendants. Disease of the mother during pregnancy is a not infrequent determining cause, such as instanced by Bourneville in a case having variola during the sixth month of pregnancy. Other conditions—for example, emotional excitement and accidents during pregnancy—seem to exert an influence on its origin. In some instances no determining cause will be ascertained.

**PATHOLOGY AND MORBID ANATOMY.**—The true pathogeny of primary hydrocephalus is unknown. It is generally explained as being due to a chronic intraventricular meningitis, a congestion of the ependyma. But in many of these cases nothing abnormal is observed about the ependyma save thickening. It is possible that a careful study of the manner of secretion of the cerebro-spinal fluid and of the relations existing between the ependyma and the external serous membrane of the brain may help to elucidate the origin of the disorder; for there is some reason for believing that a sort of current of fluid flows from the ventricles into the exterior serous cavity through the foramen of Magendie, the foramina of Mierzejewsky, and two other foramina which have been described but are of uncertain existence. The ventricular walls secrete the cerebro-spinal fluid and the exterior serous cavity absorbs it, according to this theory. Thus, then, there may be three processes by which primary hydrocephalus may be induced: hypersecretion in the ventricular spaces, occlusion of the foramina mentioned, and disorder of the absorbent apparatus. An interesting study of the subject along this line might be made.

When the fluid begins to increase in the ventricles, these become dilated, as a rule equally, occasionally unequally from obliteration of the foramen of Monro. The dilatation may be restricted to the lateral ventricles, or may include the third and fourth also. With the distention of the ventricles compression of the brain substance takes place, giving rise to functional impairment of various kinds and degrees. With increase of pressure, atrophy of the compressed parts occurs. The septum between the ventricles may disappear and the brain en-

velope become thin as paper, so that the hydrocephalus is like one enormous cyst filling the cranial cavity. The basal ganglia and brain stem become flattened. Examination of the cerebral envelope shows atrophy and degeneration of cells and fibres. The distention may go on until the cerebral tissues and the membranes vanish almost altogether. The amount of fluid has been known to reach six, eight, ten, twenty, and even twenty-seven pints. The following is an instance in point (a case from the Randall's Island Hospital for Idiots, the autopsy of which I reported at the New York Pathological Society—see Proceedings, 1894, page 91):

A female child, aged eighteen months; hydrocephalus, whether congenital or acquired unascertained. Circumference of head, 51.5 cm.; antero-posterior diameter, 18 cm.; greatest transverse diameter, 15 cm.; naso-occipital arc, 32 cm.; binauricular arc, 34 cm.

Blindness and nystagmus; widely gaping fontanelles; spastic diplegia; occasional convulsions, and just before death opisthotonus. At the autopsy sixty-four ounces of reddish serum were first removed by tapping the anterior fontanelle. The skull and dura were exceedingly thin. The falx cerebri had disappeared. Cutting through the thin dura, nothing was to be seen in the great cavity of the head of any brain proper. The membranes usually covering the cerebrum had disappeared with that organ. At the base of the skull the floors of the ventricles and the basal ganglia stood out promi-

in the right hemisphere, over the whole of the temporo-occipital region, the wall of cerebral substances was but a millimetre in thickness, and at one place here near the fissure of Sylvius, the brain substance was absent altogether at a space of four centimetres in diameter, closed merely by a fine meningeal veil. In this case, then, the process of complete atrophy of the brain was arrested by death.

As the ventricular cavities dilate, pushing the brain envelope with them, the skull cavity is distended, and the cranial bones are separated, made thinner, and expanded in area. The enlargement of the head is directly proportional to the youth of the patient. Cases beginning before or shortly after birth will present greater expansion of the cranial cavity than such as have a later origin. Sometimes some sutures give way and others become synostosed. Where sutures are separated, Wormian bones often form, or a membranous connection is established between the cranial bones.

Occasionally in these cases of primary hydrocephalus, the defects of brain substance are not due to pressure-atrophy, but there is an associated condition of malformation or defect. Thus, in an autopsy of Bourneville's on a girl, about thirteen years of age, with congenital hydrocephalus, idiocy, and epilepsy, the hemispheres of the cerebellum were totally absent, the cerebellum being represented by the vermis, which was the size of a pigeon's egg. Perhaps such a defect and others which have been described, are due to a pressure-atrophy beginning very early in foetal life.

As regards the pathology of secondary hydrocephalus we possess more definite knowledge. In this the internal hydrocephalus is caused by obstruction of the veins of Galen or by obliteration of the foramina of Monro, Magendie, or Mierzejewski. Common causes are tumors of the cerebellum, such as sarcomata and tubercles. Meningitis may act in the same way. The amount of hydrocephalus, ventricular dilatation, and expansion of the skull thus induced will depend directly upon the youth of the infant or child. As a rule, secondary hydrocephalus never reaches the extent of the primary form, owing to the rapidly fatal nature of its cause. In these cases we seldom see pressure effects beyond flattening of the convolutions and moderate expansion of the cranial vault.

The cases of acute hydrocephalus due to meningitis serosa, and the cases in which a defect of brain substance is counterbalanced by an equal bulk of cerebro-spinal fluid, do not commonly fall under the heading of this paper.

In chronic hydrocephalus internus there seems to be a special susceptibility of the membranes to acute disease, so that at autopsy it is not uncommon to find evidence of an acute meningitis, simple, hæmorrhagic, suppurative, or tubercular.

The fluid found in hydrocephalic idiots has been frequently analyzed. In a case of Bourneville's the analysis of the hydrocephalic fluid, withdrawn nine hours

FIG. 1. The cranial cavity in hydrocephalus, showing basal ganglia and cerebellum intact, but only vestiges of the cerebrum (parts of the temporo-occipital lobes).

nently, and back of these parts, lying on the tentorium, were the only vestiges of a cerebrum, parts of the two occipital lobes. On removing the tentorium, the cerebellum was found to be of about normal size. Microscopical examination showed degeneration and atrophy of the lateral columns of the cord (Fig. 1).

In this case, then, we have to do with distention and atrophy of the encephalon pushed to its greatest extreme.

Case IV, in a series of autopsies by Bourneville, is a good illustration of the nature of the process of compression and atrophy: A girl, a complete idiot, died at the age of about two years. Five hundred grammes of fluid were found in the brain cavity, the brain-envelope having become merely a sac of varying thickness. For instance,

after death, resulted as follows: Color, pale yellow; aspect, clear after standing; reaction, neutral; odor, like that of blood; consistence, slightly viscous; density, 1.006; organic matter, 1.65; salts, 10; total fixed solids, 11.65; phosphoric acid, 0.22; sodium chloride, 0.80; albumin, 0.26; leucocytes, very few; red blood-corpuscles, considerable.

**SYMPTOMATOLOGY.**—The enlargement of the head is ordinarily the first symptom to attract attention. It

FIG. 2.—The naso-occipital arc in oxy-hydrocephalus.

may be so large at birth as to interfere with delivery, or the expansion may not be noteworthy until during the first months or first years of life. While there is commonly a great similarity of cephalic contour in most cases, so that we have come to look upon a certain slope of head as a characteristic type, this is by no means always true, for irregular synostoses may alter the outlines considerably (see Figs. 2, 3, 4, and 5).

In a typical hydrocephalic child the head is quite evenly expanded into a somewhat globular shape, when

FIG. 3.—The naso-occipital arc in scapho-hydrocephalus.

viewed from the lateral aspect (Fig. 6). Looking down upon the outline of the horizontal circumference, it has rather a triangular contour with the apex forward (trigonocephalus). The one illustrated in Fig. 5 has a perfect-

ly round head. The face seems puny and weazened in contrast to the enormous head above it, and is triangular in shape. In young hydrocephalic patients the fontanelles gape widely, and the sutures are often open, so that the pulsations synchronous with the pulse, the hydrocephalic souffle, and fluctuation may be perceptible. In older cases both sutures and fontanelles are commonly closed. Examination with electric light, either in the throat or at the side of the head, will in marked cases show translucency of the skull. Young children,

FIG. 4. The naso-occipital arc in another form of oxy-hydrocephalus.

through weakness of the muscles of the neck, tend to let the heavy head fall forward, backward, or sidewise. Later on the head, even though quite heavy, may be held erect. In very marked cases the head is never held up at all. The forehead may be wrinkled as if in pain, though ordinarily in slowly progressive patients the face is placid. There is generally a superciliary depression.

FIG. 5.—An oxy-hydrocephalic idiot at Randall's Island.

The features are pale, and on the thin white skin of the face and head the blue veins stand out markedly. Dentition is commonly retarded, and the teeth are badly preserved, though sometimes they are exceptionally fine. Squint and nystagmus are not infrequent.

**GENERAL PHYSICAL CONDITION.**—Rhachitic deformities of the thorax are not uncommon, such as the thoracic chaplet, exaggeration of the curvature of the posterior angle of the ribs, and slight kyphosis or scoliosis, or both. The abdomen is frequently enlarged. The pelvis is seldom affected except in rhachitic cases, where its altered position is purely compensatory. There is general muscular weakness. Anæmia and emaciation are common,

and nutrition, as a rule, is so impaired that a great number have a sort of progressive cachexia or marasmus. They usually die of pulmonary congestion. There are exceptional cases, however, in which the general health is excellent. Subnormal bodily temperature is the rule in hydrocephalus. Increase in weight and bodily growth

FIG. 6. — Three cases of hydrocephalic idiocy, showing typical head contours.

often proceed as in normal children, except in cases presenting paralyzes. Puberty is apt to be retarded in bad cases. Learning to walk is retarded considerably, even if no paralysis be present, when the disease begins early. The gait is apt to be affected by the difficulty of balancing the head, so that it is slow, shambling, weak, and awkward to a degree depending upon the extent of the interference.

**PARALYSIS.**—Very often we meet with paralyzes which differ in degree and character as much as do the infantile cerebral palsies in general. They depend usually upon pressure-atrophy of the cerebral segments of the motor tracts. Hence their development is slow—first a paresis, then complete paralysis; we meet with monoplegias, hemiplegias, paraplegias, and diplegias. As a result, we find in the paralytic limbs retardation of growth, exaggerated reflexes, and spastic contractures. Hemiplegia naturally signifies a greater increase of ventricular fluid on one side than on the other, or suggests dilatation of one ventricle alone. I have not observed in this species of infantile cerebral palsy the methemiplegic movements common to other forms. When hydrocephalus is suspected of being secondary to cerebellar neoplasms, the motor disorders characteristic of such lesions should be looked for.

**EPILEPTOID CONVULSIONS.**—Convulsions not only generally usher in the last stages of the disorder, but they are not at all infrequent during its progress, constituting sometimes a real symptomatic epilepsy. Occasionally the epilepsy is local—a hemi-epilepsy—but general convulsions are the rule. While we are disposed, as a rule, to look upon such explosions as cortical in their origin, episodes significant of critical increases of cortical pressure, this is not always true. My case, reported above, of a hydrocephalic child with scarcely any cortex left in its wasted brain (portions, too, of only the temporo-occipital cortex) was further remarkable in that it had occasional convulsions, the last at the time of its death.

**GENERAL AND SPECIAL SENSIBILITY.**—Cutaneous sensibility is rarely affected, except in extreme cases where the sensory tracts are involved. Taste, hearing, and smell likewise seldom suffer. Enfeeblement of vision and great myopia are constant symptoms, and total blindness is quite common. In primary hydrocephalus there is rarely any pain or headache.

**PSYCHOLOGY.**—The mental symptoms in hydrocephalic idiocy vary greatly according to the degree of injury to the intellectual substratum. The tendency is to progressive enfeeblement along all lines of psychic growth, so that we find among them each degree of impairment, from feeble-mindedness to imbecility and complete idiocy. Where the malady is considerable, the patient finds it difficult to support the head, and, consequently, inclines to lie in bed or to sit still with the head hanging down. He gradually loses any play of expression he may have had. The sad, dejected look is commonly the last expression to take its departure. A profound apathy is noticeable in looks, attitudes, and movements. The faculty of attention gradually loses its sharpness and grows more and more unstable.

In the early stages he has all of the normal instincts, but with the evolution of the disorder these fade away, and the patient enters upon a purely vegetative existence, with a tendency to sleep and to speak little if he speak at all. The hydrocephalic idiot is ordinarily timid, fearful, gentle, neither affectionate nor mischievous, with a certain refinement of face, expressive of sadness and languor. Sollier looks upon the hydrocephalic idiot as a complete contrast to the microcephalic. Language is apt to be slowly developed, and later slowly lost. The will is almost absent as a rule. Memory is at first fair, then gradually impaired, and, finally, vanishes wholly. A peculiarity in a considerable number of cases of hydrocephalus is a tendency to sudden accessions of anger, which Bourneville very suggestively compares to the convulsive crises of the malady. Co-ordinated ties, such as antero-posterior and lateral oscillation, are sometimes met with in this as in other forms of idiocy. The sentiment of vanity seems to be rather strong, especially among hydrocephalic females. While the mental faculties are generally much impaired in all directions in severe cases, distinctive psychological features can not be portrayed in connection with hydrocephalic idiots, and it is often remarkable how much intelligence and expression may remain in an individual apparently afflicted to the extreme degree.

**COURSE AND DURATION.**—Nothing is more uncertain than the course of hydrocephalus. Sometimes beginning before birth, the process may cease for a long period or altogether. In the greater number of cases it is a few months after birth before the increase of fluid begins to manifest itself, the infant up to this time developing like normal children. Then convulsive crises or meningitic congestions announce a new inception of the malady. Spontane-

ous recoveries or arrests are not infrequent. On the other hand, the progress may be steady and continuous and slow or rapid. The inception of the disorder may be so insidious and the course so protracted that it is only discovered by accident (the misfit of a cap or hat) that anything is wrong. Some idea of the varying progress of cases may be gathered from the following cephalic measurements taken from Bourneville's reports:

CASE.	I.	II.	III.	IV.	V.	VI.	VII.	VIII.	IX.
YEAR.	1885	1887	1886	1888	1887	1888	1893	1886	1889

Bimauricular diameter.	16.0	16.5	18.0	18.6	11.2	14.5	14.0	15.0	13.5

Rokitansky reports a case of enormous hydrocephalus where spontaneous rupture through one of the sutures took place with the result of ultimate recovery. The common termination of the disease is from bronchopneumonia or meningitis at the average age of three to six years.

DIAGNOSIS.—It is not often that there is any difficulty in diagnosing the affection when progressive enlargement of the head, with separation of the sutures and thinning of the cranial bones, is apparent. There are cases of cerebral hypertrophy and of hyperostosis of the cranial bones which may at times be confused with chronic hydrocephalus, though it must be remembered that the meningitic and convulsive crises of the latter are distinctive. The most puzzling cases are those of hydrocephalus acquired after union of the sutures. These are, however, rare cases, and, as a rule, symptomatic of other cerebral affections. In hydrocephalus which appears to be symptomatic, headache and vomiting, absent in primary hydrocephalus, should suggest neoplasm as a cause. Lumbar puncture for the withdrawal and examination of the cerebro-spinal fluid for bacilli should be resorted to whenever the question of tuberculous meningitis comes up as a question of diagnosis.

The ophthalmoscope should be employed to determine neuritis and atrophy of the optic nerve, not found in cerebral hypertrophy or cranial hyperostosis, but not infrequently in hydrocephalus.

PROGNOSIS.—Naturally, the prognosis is grave. Death in childhood from some intercurrent affection is the usual termination, though spontaneous arrest of the progress of the disease, with a fairly long life subsequently, is known to occur at times. Complete recovery is, of course, extremely rare, for the damage done to the brain by retardation of its development or by abrogation of some of its functions can be only faultily repaired. If much harm has already been done, such as the onset of paralysis of a limb or limbs, or the production of

blindness, the probability of an individual's survival beyond childhood is small. Bourneville quotes Gratiolet as believing that a certain degree of hydrocephalus, by dilating the cranial cavity, may favor the development of the brain, and thus give rise to intellectual growth of a high order, as instanced in the case of Cuvier. It is certainly true that in our social life we occasionally meet with individuals of intellectual superiority whose cephalic contours would indicate an arrested chronic hydrocephalus. Thackeray has been cited as an instance of genius coexisting with hydrocephalus. However this may be, I am inclined to agree with Bourneville that the skull is an elastic vestment of the brain depending for its growth altogether upon the development of the encephalon.

TREATMENT.—The treatment of chronic hydrocephalus of the simple, primary kind is medical or surgical. Bourneville sums up the medical treatment, which he has found successful in some instances, as follows:

1. Compression (Barnard, Trousseau).
2. Revulsives (Gelis).
3. Internal administration of calomel (Gelis).

The head of the child is shaved and a capeline bandage is kept applied for a week. After a week's rest, it is renewed, or, if any incident contraindicates this, daily friction with mercurial ointment is substituted. At the same time calomel is administered twice weekly, in one-and-a-half-grain doses. Every month, for a year or more, a vesicatory is applied to the head for from fifteen to twenty hours, and when it begins to dry compression is again employed. In addition to this, exercise, massage of the limbs, salt baths, douches, tonics, etc., are used as required. Pedagogic treatment is important for this class of cases when cure or arrest of the disorders seems evident.

Thus far surgical procedure of any kind has not proved to be of particular value. Most patients have died as a result of operation. Possibly a more conservative method of operating may be devised in the future. Up to the present time the surgical procedures resorted to have been (1) craniectomy and drainage; (2) puncture of the lateral ventricles; (3) puncture of the fourth ventricle; (4) lumbar puncture.

Craniectomy with drainage may be excluded nowadays altogether from the category of expedients. The patient is almost certain to die as a result of the sudden evacuation of a large amount of fluid.

Puncture of the lateral ventricles, even if carried out carefully and skillfully according to Keen's method (*Medical News*, December 1, 1888), promises but little more, and had best be abandoned as a remedial measure in this class of cases.

Trephining of the occipital bone, three fourths of an inch below the superior curved line, to the right of the middle line, with subsequent enlargement of the opening downward, and the insertion of a probe into the fourth ventricle, is an operation which was proposed by

Parkin (*Lancet*, 1893) and carried out in four cases with the recovery of two. It seems to me that on theoretical grounds this form of procedure has much in its favor, and it deserves more extensive trial. Another similar measure, successfully tried, is trephining in the region of the temple and insertion of the cannula in the sub-arachnoid space of the fissure of Sylvius.

Lumbar puncture, by which is meant the insertion of a drainage needle through an intervertebral space in the lumbar portion of the spinal column into the spinal cavity, has been rather extensively employed of late in a great variety of affections of the central nervous system, hydrocephalus being among them. Jacoby (*New York Medical Journal*, December 28, 1895, and January 4, 1896) has recently made a careful study of the subject of lumbar puncture in connection with a number of central nervous maladies. Quincke seems to have been the originator of the method (Tenth International Congress, 1891), though Wynter (*Lancet*, 1891) proposed it about the same time. It seems to be a simple and harmless procedure, as well as a powerful means of reducing intracranial pressure. An ordinary aspirating needle (a millimetre in diameter, eight centimetres long) is aseptically employed. The space between the third and fourth lumbar vertebrae is selected, five millimetres to the right of the median line, though in children the puncture may be made directly in the median line. An anæsthetic is rarely required. The needle should be pushed in for from two to eight centimetres. The fluid begins to flow out in drops or in a small stream according to the degree of intracranial pressure. The amount of fluid allowed to flow out must be gauged by the indications and conditions. Fürbringer withdrew in one case a hundred and ten cubic centimetres at one time. On removing the needle, the puncture is closed with a little iodoform collodion and a compress with adhesive plaster. Fürbringer, Heubner, and Ewald report temporary improvement in hydrocephalus after lumbar puncture, but the method is as yet too novel and has been too little used to allow of any definite conclusions as to its value in this class of cases. Several cases of recovery from hydrocephalus by means of this measure have been reported.

Operation does not preclude the employment of other means also. Horizontal bandaging of the head with a wide rubber bandage after tapping, and the use of cod-liver oil and phosphorus, are certainly of considerable service, and should not be neglected.

60 WEST FIFTIETH STREET.

**Boxing the Ears.**—A medical magistrate (Dr. Hetley) at Penge has drawn attention to the evil effects of boxing the ears of school children, and to the duty of avoiding this form of punishment, not only from the harm which results to the ear itself, such as rupture of the membrana tympani and concussion of the labyrinth, but from the even more serious consequences caused by the resulting supuration in the middle ear. It should also be recognized that the inattention of children is, as a rule, due to impaired hearing—a condition which in itself often renders the ears more liable to injury from blows.—*Brit. Med. Jour.*

## SOME NOTES ON TWO CASES OF SARCOMA OF THE NASAL CHAMBERS AND ACCESSORY SINUSES.\*

By ARTHUR AMES BLISS, A. M., M. D.,  
PHILADELPHIA.

At the German Hospital, of Philadelphia, during the past year, we have had the unusual experience of receiving two children, one four years of age, the other nine years, suffering from large sarcomatous growths within the nasal chambers.

**CASE I.**—Walter W., aged four years, family history is excellent. One year ago last January (1895) it was noticed that the left nostril of this child was becoming occluded. The surgeon who examined the nares at this time pronounced the case to be one of nasal polypi, and removed considerable spongy, myxomatous tissue. Six days after this operation the growth recurred. The parents of this child state that during the succeeding eight months the occluding mass was cleared away by means of forceps as many as thirty times. After each attempt at removal, however, the growth recurred promptly, each time involving an area larger than before. The child was admitted to the German Hospital on September 2, 1895. I saw the case two weeks later. The condition presented then was as follows: A soft, fungoid mass of coarse granulations was visible just within the left naris, appearing to fill completely this side of the nose. By its pressure the septum had been forced far over into the right naris, being pressed almost against the outer wall of this side. There was tenderness over the maxillary antrum of the left side, but no swelling. The left eyeball protruded from its orbit and was forced forward and outward. The posterior naris was filled completely with a soft myxomatous tissue which pressed downward against the soft palate. The external auditory canal of the left ear was filled with a similar growth of tissue. There appeared to be no involvement of the cervical lymphatics. In attempting to clear away these masses within the nares, I decided not to resect the superior maxilla, believing that such success as we could expect from any attempt at removal would follow as well from a simpler operation. I opened the maxillary antrum of the left side by dissecting the cheek from the underlying bone and raising it so as to expose the canine fossa and that part of the superior maxilla forming the outer wall of the antrum of Highmore. This bony wall was then removed by means of drills and a chisel, so that a good view was obtained of the interior of the antrum. This space was found to be packed tightly with the fungoid mass, which was removed by curettes, and the bony walls scraped. The roof, separating the orbital cavity from the antrum, was found to be intact. Having freed this sinus, I broke down the inner wall by means of cutting forceps, and, using the same instruments, cleared away the tissue within the anterior nares. This resulted in the removal of the larger portion of the lower and middle turbinated bones. I then introduced a forefinger into the posterior nasal space, passing my hand back through the patient's mouth. This finger was used as a curette, and served as a guide for a cutting forceps, which was passed through the left naris into the post-nasal space. The

\* Read before the American Laryngological Association at its eighteenth annual congress.

finger, aided by the cutting forceps, removed the masses of the growth from this area, and the surrounding bony walls were scraped. Considerable hemorrhage attended the different stages of this operation, but the area was thoroughly cleared without having made any large external wound. I packed the antrum with iodoform gauze as a daily dressing, and touched the raw surfaces with a strong solution of nitrate of silver, dusting iodoform into the nares and post-nasal space. The growth did not recur in the area operated upon, but the protrusion of the left eyeball was only very slightly reduced. During the six weeks succeeding the operation, the cervical lymphatic glands at the angle of the jaw and submaxillary region became greatly enlarged. The child began to manifest considerable difficulty in respiration. This was not due to any mechanical occlusion of the larynx by reason of enlarged lymphatic glands, but appeared to be of central origin. A series of short, ineffectual inspirations would be followed by a prolonged expiration, after which the child would breathe easily for a time, until another seizure of the same character would occur. The child was removed to its home on October 12, 1895, and died from exhaustion about six weeks later.

CASE II.—James S., aged nine years; family history good. Admitted to the German Hospital on April 2, 1896. The accompanying photograph illustrates very

CASE II.—Sarcoma of the left naris.

well this child's appearance, showing the growth protruding from the left naris, the marked exophthalmia, and the swelling of the cervical lymphatics of the left side. Until three weeks before admission, the child is said to have been well. His general condition was wretched, and it was not deemed advisable to attempt any operative treatment. He has returned to his home and, at the time of last report, was still living.

These two cases are somewhat unusual in the rapid development of the growths and in the early ages of the patients. As no autopsy was held in Case I, we can not state in what area of the nasal chambers the sarcoma took its origin. There is, however, a certain sequence in symptoms which is suggestive. In Case I the patient complained first of pressure high within the left naris;

then, of occlusion to breathing; then, of pain in the left ear and otorrhœa; then, of rapidly increasing exophthalmia.

The replies elicited from the parents of Case II give a somewhat similar history, although pointing to a much more rapid development. I would suggest, therefore, that both growths had their origin in the middle turbinate of the left side or within the ethmoidal sinuses; that they followed the paths of least resistance from their origin, growing downward to the floor of the naris, forward, backward to the post-nasal space, outward to the antrum. That then they began to work their way into more resisting structures, the Eustachian tube of the left side, involving, perhaps, the lymphatics about it, and thus reaching the ear; into the ethmoidal sinuses, and, later, the sphenoidal sinus, thus forcing the eyeball forward and outward. Finally, they began to involve the lymphatic chain in the neck.

Case I illustrates plainly the need for most radical measures in this class of cases. If the work is not to be most thoroughly done it had better not be attempted.

The method of operation followed in this case gave us free access to all parts of the area involved except the sphenoidal sinus, and, although somewhat more effectually reached, the ethmoidal sinuses. I doubt if a resection of the superior maxilla, and of the entire body of the nose, would have enabled me more effectually to reach these distant recesses into which the growths had penetrated.

#### SOME REMARKS ON ACUTE DISEASE OF THE LINGUAL TONSIL.\*

By H. L. SWAIN, M. D.,  
NEW HAVEN, CONN.

PRIOR to 1884, when medical writers first called attention to the lingual tonsil, little had been observed about the peculiar strip of adenoid tissue situated at the base of the tongue. For many years it had been known to exist, the character of its tissue had been studied macroscopically and microscopically, and since the days of the laryngoscope its likeness had been present in every laryngoscopic picture, forming as it does the background for the epiglottis, and yet its importance had not been dreamed of, so little attention was accorded it while looking into the more interesting and better known larynx. About that time several different writers called attention to the fact that chronic enlargement of this, like any other part of the ring of adenoid tissue which surrounds the upper part of the pharynx, could and did take place, and caused when present certain symptoms, so definite in type that from description alone one might almost diagnose the case.

*A priori* one could have readily deduced the idea

\* Read before the American Laryngological Association at its eighteenth annual congress.

that of course this tissue would also participate in all acute inflammation of adenoid tissue; yes, might itself be the only part attacked; but one finds in literature only very few observations recorded until within a few years. Nowadays one sees rather frequent allusions to this kind of acute inflammation, but I fancy that many—yes, very many—cases of this acute disease pass even to-day unnoticed, masked as they are by trouble higher up and better to be seen, and are surely deserving of much more care than is often accorded them. To judge by literature, this last point is more than emphasized, for such reports as are published are mere accounts of the abscesses, which are of very rare occurrence in proportion to the number of acute troubles of this organ, while if mention is made at all of the simpler forms, it is in the most cursory and superficial way. For example, Seifert,\* writing in 1893, finds mention of some sixteen or seventeen cases of abscess from almost as many different sources, but only makes reference to eight articles where the simple form of trouble was discussed, and of these latter eight some names are included among those reporting abscesses. He had himself had at that time but three or four cases of acute inflammation of the lingual tonsil and one case of abscess.

Simonowski,† writing in the same year, found that he had twenty-two cases of acute inflammation in the lingual tonsil, eight of which had been of the peritonsillar type.

Since then a number of articles have been written on the matter, and some few cases of abscess have been reported; but, so far as my knowledge goes, none of them have considered the subject as thoroughly as the two mentioned.

In 1886 I published the results of some studies on the lingual tonsil, and have ever since been following closely the treatment of the chronic enlargement, alert for its every manifestation, yet only since 1892, when I had my first case of abscess, have I been mindful of the more acute phases. Now, however, I find the acute trouble really so frequent that I have this winter treated at least twenty cases of acute affections, and am sure that I have not correlated all that I might under that head. I have been particular to consider as such only those cases where the lingual tonsil not only looked and felt worse than any other part of the throat, but where the treatment directed to that part was the only treatment which gave any relief to the patient. In almost every case of badly inflamed fauces the lingual adenoid tissue will be red, and *vice versa*, so that the part most inflamed must be considered as claimant for the attention. Frequently, too, a faucial amygdalitis may be followed by the lingual, and, as in the former so in the latter, it may be an acute excitement on a chronically enlarged organ.

However much difference of opinion there might be

as to the frequency of this form of trouble, there can be no doubt of its occasional existence, and so I beg of you to bear with me while we consider some of the details.

In considering what sort of an organ we are dealing with, it must be borne in mind that by situation and in its anatomical peculiarities it is materially different from the faucial tonsil. It consists of an irregular flat strip of tissue stretching across the base of the tongue, lying between the papillæ circumvallatæ and the epiglottis, merging sometimes by direct continuity into the lower outshoots from the faucial tonsils. It is superimposed upon a firm base of solid muscular bands, fasciculæ from which run into its substance and interlace between the crypts. In thickness it is seldom more than an eighth of an inch, and when most thickened rarely measures more than three eighths of an inch. The crypts themselves, instead of being tubes, are shaped irregularly like the bowl of a lamp. Very little loose cellular tissue exists between it and the muscles, except downward and backward, where the muscles of the tongue radiate to meet their attachments on the hyoid bone, palate, and styloid process; there occurs in connection with the epiglottis some looser cellular or connective tissue. Directly over this tonsil must pass everything which goes into the œsophagus, and fluids especially have abundant chance to soak their way into its crypts and through its spongy epithelium, ready to be transported thence into the systemic circulation, for nothing could be richer than the blood and lymphatic supply of this region. So rich, indeed, is the former that the blood-vessels well-nigh form a plexus thick enough to be styled erectile. In fact, that the organ is important in this respect can be readily observed when it is considered how much dilatation the superficial veins suffer when there is any pressure on the larger trunks by enlargement of this organ, as evidenced by the varices so often seen on the base of the tongue anterior to the tonsil. The situation of the tissue further involves that every motion of the tongue in either swallowing or speaking is participated in by it, by no means a small item when it is acutely inflamed, and when enlarged it would most easily hit the epiglottis and the faucial tonsils at the side. This tonsil is developed much later than the faucial; in fact, the actual follicles which gather in the walls of the crypts, and make the distinction of this kind of tissue, are formed after birth. I have found them entirely absent in a child's tongue of six years, and very infrequent in one ten years old.

How different is everything in the faucial tonsil! Larger, thicker, loosely attached, easily adherent, earlier inflamed, and earlier developed, we should expect it to be more susceptible to acute trouble, and, the latter present, we should expect more swelling, more retention of foul products, severer constitutional symptoms, better facilities for deepening and spreading of the inflammation and of formation of abscesses, and finally the chronic enlargement more frequent, greater in size,

\* Fraenkel's *Archiv*, Bd. 5, S. 48.

† Reference in *Inter. Centrall. für Laryngologie*, etc., July, 1894, p. 24.

and more often acutely inflamed. On the other hand, the lingual tonsil is more liable to receive whatever of irritating and septic matter the ingesta of secretion of mouth and throat may contain, for all matter swallowed traverses it, and, being at the bottom of the throat, it gets the drippings from all the rest of the throat and overlying parts. However, these things seem to have little weight except as years go by; for just as in the very young child we more frequently see adenoid enlargement at the vault of the pharynx, in childhood and youth a greater tendency to enlarge the faucial, so in adult life, beginning any time after puberty, there seems to be an increasing tendency to inflame the lingual tonsil. Given, however, acute inflammation, we should expect but little swelling, as there are no adhesions, but little retention of foul products, and so more rarely circumtonsillar or deep-seated inflammation with formation of abscess. Should, however, an abscess develop, we should expect, as in quinsy, to find the formation of pus in the region where there is the nearest approach to a dead space, backward and downward toward the outer edge of the epiglottis. Swelling in this region would lead to pressure on return circulation of the surrounding parts, and there would be involvement of the epiglottis and glottis. In severe cases there would be oedema. As a matter of fact, these cases are rare, and even the severer forms are infrequent, just as we might infer from anatomical conditions. I have seen but two cases of abscess, the last being a year ago, while I have on record forty cases of undoubted acute affections of the lingual tonsil. These I have seen in the last two or three years, and of these only four or five could be called peritonsillar in type. They were all in persons over eighteen years old, and more between the years of twenty-five and forty. Eight in every ten had had previous attacks, or at least I judged them to have had chronic enlargement previously present. They all coughed some, most of them distressingly. Otherwise they had nothing different than one finds in such cases, and certainly presented, as regards frequency of the severe type of disease, marked contrasts to the same disease in the fauces.

In speaking of my cases of the acute inflammation and involvement of this tonsil, I have been particular not to mention their character except to refer to the abscess. Whatever inflammation may attack a faucial tonsil may, of course, inflict itself upon the lingual, and so we distinguish first the simple form, when a chronically enlarged tonsil is acutely reddened, swollen, and painful; the follicular variety, where with constitutional symptoms well marked, either alone or together with the faucial, frequently following the latter on the third or fourth day, the lingual tonsil exhibits well-marked plugs of mucus, which occasionally spread to an actual membrane; the circumtonsillar type, where the deeper structures are affected, and which occasionally results in abscess; and finally, true diphtheria has begun

on the lingual tonsil, or the latter has become involved in a diphtheritic process.

To go into the history of the causation of any or all of these varieties is but to rehearse all that is known on these same matters when connected with the other tonsils.

The first variety spoken of is vastly the more common, and is usually very simple when uncomplicated. The patient complains of having caught cold and has a sore throat. He generally volunteers that it is not in his tonsils, except where they are involved, but lower down, where one swallows, and points to the region of the hyoid bone. There is also the feeling of a lump, which makes swallowing painful, and commonly, if the swelling involves the lateral edge of the tonsil, shooting pains run upward toward the ear. More often than not, especially when there was much previous enlargement, cough is complained of, and, in fact, so frequently is this a cause of cough, as almost the only symptom of the trouble present, that I never fail to try the possibilities of treatment in every case of throat cough which is uncontrolled by simple remedies, or has not a known, definite, and sufficient cause. It always requires something to make a cough. Irritation exists somewhere, and especially when on lying down or going in or out the door, or on using the voice, a sudden explosion and prolonged coughing spell comes on, without raising, and due, as the patient frequently himself is conscious, to a tickle in an especial spot, one will find very often the hyoid region to be indicated. Something seems to be wrong in that region, and it is common to blame the poor larynx for it, often, 'tis true, with right. But sometimes the patient may be more accurate, and point to a spot on one side, and here, as in other cases, without his aid, if accurate observation is made, the physician can find the spot to correspond exactly with the reddest and most swollen spot in the lingual tonsil. This spot will be found to be where it can rub on the epiglottis or on one of the faucial tonsils. Contact of spots usually not in touch with each other in the throat always causes some disturbance of feeling, as is indicated by the feeling of the lump usually present in any enlargement of this tonsil. But sometimes the feeling is interpreted as a tickle which produces cough. The very contact keeps the parts irritated, and, when they become lacking in moisture, of course the friction is more severe. As stated in the anatomical remarks, the lingual tonsil possesses by virtue of its rich supply of blood-vessels possibilities of sudden enlargement by their becoming engorged, amounting to almost an erectile type. Granted now that by acute inflammation the tonsil is swollen and the parts are almost in contact, and the drying and irritating effects of mouth-breathing at night, or in going out, or perhaps mere emotion, suddenly send more blood to the parts. Immediately contact is established, and either or both of two results must ensue. If large surfaces come into contact by the swelling, the patient is con-

scious, sometimes painfully so, of a lump. If a small projecting spot suffers the distention, a small irritation ensues, the exasperating tickle, which continues in spite of everything the person can do, throwing him into convulsions of coughing, if the temperament is such, until by very exhaustion, or mayhap by the skilled physician's touch, the swelling reduces. Then as by magic the cough stops, and the patient dries his tear-stained face, wondering what could have made him have such a time, and he does not have another until those spots come together again; the intervals being short in acute cases, in chronic enlargement even days. If a cough is purely laryngeal, coughing and clearing the throat accomplish something in the way of stopping it. If bronchial, it stops by raising. When it is the lingual tonsil, coughing rather of the two aggravates the trouble. Sometimes, however, as stated, there is no help given the physician by the patient in locating the trouble; in fact, he may confuse him, for, as pointed out in speaking of chronic enlargement, there is sometimes an oppressive feeling produced by this trouble, which is referred to the chest. In the same way occasionally the patient will insist there is a tickle way down in the chest, when curiously enough an application to the lingual tonsil will remove the trouble. I suppose some reflex effect on the vagus explains this deception.

I have spoken at length of this one symptom, because the others of an acute trouble generally last but a day or two, but this one is present at the start, and lasts frequently for weeks afterward; in fact, distressing cough of this type may last for months following one of these attacks. The pain, as in other acute affections, is not always commensurate with the amount of local symptoms, and frequently streaks up toward the ears with each attempt at swallowing. Sometimes an intolerable heat or burning is complained of, which at intervals is very much worse. The feeling of a lump, which is so frequently present, is so strong that frequent and repeated attempts are made to swallow it away, or to hawk it up; each attempt, however, only adds to the pain. Loss of voice is very frequent, but is of a reflex type, fatigue being a prominent item. Often also talking produces pain. The constitutional symptoms amount to fully as much as an ordinary tonsillitis; the frequent occurrence of this variety of trouble in connection with attacks of *la grippe*, however, makes an estimate of the amount of prostration to be attributed to the local trouble very difficult.

The follicular variety, however, has much more fever, decidedly sharper local symptoms, and a quicker decline than the other variety, differing but little from it in the general history except that the pain and local symptoms frequently are closely dependent on the presence of the plugs of mucus in the crypts, and are immensely relieved by their removal. When the whole lingual tonsil is affected, there is a feeling of stiffness on the motion of the tongue. Several of this winter's cases

have shown a marked tendency to affect only a part at a time, and to relapse through two or three weeks, going from one part of the tonsil to another. Where this is the case there is frequently a crescendo in the type, so that I have imagined a very small abscess may have developed in the last spot affected, for the diminuendo has been as sharp as after a quinsy; but I have no absolute assurance. Except for a case of the relapsing type, the patients improve under a simple treatment, and in from three to six days are better of the pain and soreness, the cough, as before stated, frequently being troublesome for a much longer time.

When the peritonsillar infiltration becomes a feature of the trouble, the whole aspect is much more severe. If the extent of the tonsil involved be great, the whole tongue becomes swollen, oftener on one side, so that there is hardly room in the mouth for it. All motions are very difficult, and swallowing on the fifth or sixth day will become well-nigh impossible; although the necessity for it increases owing to the salivation. The epiglottis about this stage, if not before, has become involved, and the whole glottis may be dangerously cedematous. This swelling, aside from the threatening aspect as regards respiration, is very annoying in swallowing. The glands in the neck on one side are swollen; sometimes the entire neck in the hyoid region, and toward the angle of the jaw, will be protruding and hard. The tongue itself posteriorly has the hard, tense feeling to the finger which the palate has in ordinary quinsy. Sometimes also, as in the latter, the focus of pus can be distinctly felt as a soft, pulpy mass. Oftener, however, resorption takes place without this latter, and in the course of ten days or two weeks the patient recovers. In these cases, however, swallowing is a very serious symptom, and the lack of food and nutrition weakens the patient as in the other kind of quinsy. The cough in this variety is a most distressing symptom, for the pain it produces is agonizing. If the abscess opens spontaneously, or is lanced, there is immediate improvement, and rarely does the convalescence exceed a week thereafter.

The treatment of these various forms of lingual inflammation would divide itself into general and local, and the latter into measures carried out by the patient and by the physician. For the general treatment I have nothing further to say but that I am rather fond of trying to break up the inflammation at its beginning. Not succeeding, I always follow the initial medicines, where I have the least indication, with antirheumatics. I am sure they help us frequently to abridge the process. The first night I invariably use a Priesnitz poultice, otherwise nothing different is done than the usual systemic treatment of a tonsillitis.

Locally early in the treatment the patient may use cold, as pieces of ice held in the mouth; later these are also very comforting when the process is well advanced. Every two or three hours the patient is directed to gargle,

if the trouble has advanced, with milk and water, half and half, and as hot as can be borne, at least a glassful being used at once. This is followed immediately by half a glassful of water in which some alkaline preparation has been dissolved. I am accustomed to use potassium chlorate and borax together as being about as soothing and comforting as anything I can find. Between times, in the severer cases, the tedium of the distress in the throat is relieved by spraying with cold solutions of Seiler's tablets. Where the distressing cough comes into play, and, in the phlegmonous types, the swelling is intense, and there is inflammation of the glottis, steam inhalations must be adopted and used freely. The nourishment is, of course, bland, easily digestible, and mostly fluid. As often as I see the patient I apply to the inflamed areas, especially on the spots where I think contact exists, after thorough spraying with an alkaline solution, boro-glyceride, or, more strictly speaking, glycerite of boro-glyceride, and then insufflate directly on top of this a powder of tannin and morphine sulphate, the latter being in about the proportion of two and a half per cent. of the entire mass. An oily spray closes the performance. When serious congestion threatens, scarification of the tonsil gives some relief, as also do leeches applied externally in the hyoid region. If there is phlegmon present, and with it the usual oedema of the glottis, I freely incise the latter so as to let out the fluid. I also warn the patient of the danger of the swelling, and also of the liability of the abscess breaking and the matter getting into the larynx. Tracheotomy is sometimes a necessity. Unless it be to anesthetize the parts for the purpose of incision, etc., I do not ever feel justified in using cocaine, unless it is to make the patient more comfortable while taking some nourishment. Of course, if other parts of the throat are affected at the same time, there has to be something suitable done to them, but that may be considered as treated *pro re nata*.

Now, if not too weary, I will give a brief history of the last case of abscess of the lingual tonsil which I have had:

Mrs. D., aged thirty-five years, had been treated by her family physician for an ordinary tonsillitis of the faucial type, and which, having affected both tonsils—the right last—had got better. She went out one afternoon and was taken worse in the night, sent for her family physician the next morning, and he concluded from the symptoms that she had oedema of the larynx, and referred the case to me. I found the patient somewhat weak and anæmic from the previous illness, but evidently suffering no distress for want of breath. She was hoarse, but not aphonic. The temperature was normal, pulse rather rapid, but she did not make the impression of being a very sick patient. The examination showed the pharynx free from any membrane, the tonsils a trifle red, the right slightly more so than the left. The right arytenoid was very much enlarged and oedematous, the epiglottis not involved. The right vocal cord could not be seen on account of the swelling of the arytenoid

and processus vocalis, which was as large as a small-sized hazelnut. The swollen parts were immediately cocaineized and scarified; this latter was followed by a decided reduction in the swelling, and a great deal of relief to the patient, whose chief complaint was that it hurt her somewhat to swallow and she felt short of breath on exercise. Inhalations of steam and very hot gargles were immediately started. Examination of the urine showed existence of no kidney trouble. In the afternoon of the same day the left side of the larynx had become involved, and the whole glottis was considerably narrowed. The most swollen parts were again scarified, and the patient seemed again relieved. The treatment was made more vigorous, inhalations being taken as hot as the steam could possibly be borne, and were repeated every hour or two if the patient was not sleeping. The nurse was directed not to leave the bedside, and the patient was left for the night. In the morning the left arytenoid was swollen to twice the size that the right was at the beginning, and that side of the epiglottis had begun to be somewhat swollen and thickened. Scarification again relieved the swelling somewhat, and by afternoon the left arytenoid was smaller than the right. On the next day the right arytenoid had increased in size, and the epiglottic ligament was oedematous. The base of the tongue, the lingual tonsil, which had before not attracted my attention, was considerably swollen and very much reddened, and the palato-epiglottic fold was also reddened and enlarged. Numerous and deep punctures were made, those on the oedematous parts to relieve the serum, and on the tongue to let a little blood. The difficulty in swallowing was now a very important item; it was almost impossible for the patient to swallow half a teaspoonful at a time. Coughing was intensely painful, the pain streaking by all motions of the throat up into the ear. The status on the next day remained about the same; there was no fever, and the constitutional symptoms were in no way troublesome, except from lack of nutrition. But a very slight improvement was noted for the next three days, during which time only one puncture of the epiglottis was done. A constant ache was felt in the parts at the side of the neck, but other than that if the patient was quiet she did not suffer. On the ninth day the improvement, however, was distinctly evident, although there was still a great deal of swelling in all the parts previously mentioned, and even on the left side of the larynx the swelling persisted. From then on until the fifteenth day, although the swelling did not leave the right side of the larynx at all, the patient felt very much less pain, could swallow with greater ease, got in considerable semi-solid food, and felt better all round. I was very much at a loss to explain the continuance of the infiltration of the right side of the glottis. On the morning of the following day she complained that in the night she suddenly had become voiceless, during all the previous time having spoken in a perfectly clear voice, but not loudly. The aphonia seemed to be due to an increase in the size of the right arytenoid. A slight pricking did not seem to relieve it at all. The patient remained in this condition in spite of all the treatment we could think of until the twentieth day, when she complained of feeling sick. The throat suddenly became very much sorer to swallow, so that she had almost as much difficulty as she had had on the fourth and fifth day. The aryteno-epiglottic fold and the palato-epiglottic fold became very much swollen. The base of the tongue distinctly projected, and the space between the edge of the epiglottis and

the right base of the tongue was almost obliterated. The tenderness was extreme. Externally over the cornu of the hyoid bone a distinct swelling appeared and became extremely tender. On the following day the patient was worse even than the day before, the swelling in the neck had increased to double the size, the voice was a mere whisper, and from the swelling internally it was thought that an abscess was developing near the base of the epiglottis. We applied poultices externally, and everything internally as hot as could be borne. In the evening a deep puncture was made into the most swollen area, but failed to give any relief or let out any pus. The next day the status was exactly the same, except that nothing had been swallowed for twenty-four hours and the patient was extremely prostrated. Even at this time the patient had only developed a temperature of 100°. The swelling of the parts internally was fully as great as before, but even at this stage did not cause the tongue to protrude at all, and was not accompanied by any increase in the swelling of the parts around the entrance to the larynx; the tongue could also be used with perfect comfort in talking. By evening the external swelling had become as large as a good-sized hen's egg. Another attempt was made to find the abscess cavity, but was unsuccessful. On the next morning the patient reported that up till two o'clock that night she had had no sleep. A dose of morphine, however, had finally taken effect, and she went to sleep. On awakening she found herself very much relieved, could talk audibly, and could swallow without one tenth part of the pain she had had before sleeping. Examination showed a rupture had taken place at the point where the last puncture was made, and the swelling, both internally and externally, had become very much less. From then on the convalescence of the patient was rapid and uneventful, and by the tenth day thereafter the throat was practically well.

## BLOOD DIAGNOSIS.

### AND SOME OF THE

#### MOST IMPORTANT ADVANCES IN THE STUDY OF BLOOD.\*

By F. SCHWYZER, M.D.,

PATHOLOGIST TO THE GERMAN HOSPITAL.

It is since the forties that, together with the development of microscopy and physiological chemistry, the modern study of blood has originated. In the last ten years it has progressed so rapidly that we can look upon our present standpoint with satisfaction, and may expect in the near future a further amplification of our knowledge. We are able to diagnose from the blood a number of distinct diseases; often therapy and prognosis depend altogether upon an examination of the blood, and perhaps we shall succeed in time in establishing tables of blood diagnosis that will enable every physician to recognize not only the special diseases of the blood and malarial infection, but also other diseases due to protozoa, perhaps even measles, scarlet fever, and carcinoma. At present, it is true, the conditions are too complicated, and he will certainly be a great pathologist

who shall bring harmony into the chaos in which we find hæmatology at present.

Blood is an alkaline fluid, consisting of a liquid, plasma, and of solid elements, red and white blood-cells and blood plaques, suspended in it. For an ordinary examination, we need about six drops of blood, which are best obtained by pricking the finger with a broad needle. Of this we employ one drop for a fresh microscopical examination, one for determining the relative and absolute number of red and white blood-cells, one for making from four to six cover-glass preparations, and a few for estimating the amount of hæmoglobin. The examination of the fresh blood is just as important as its staining. Even macroscopically grave changes may be recognized by the coloration of a drop of blood; the power of coagulation may also be judged. If we look with the microscope at a drop of blood under a cover glass, we can, from the size, shape, color, etc., of the red and partly the white blood-corpuscles, draw a conclusion as to whether, for instance, we have to deal with a distinct case of leucæmia or grave anæmia or malarial disease. We may judge of the intensity of an anæmia by the degree of poikilocytosis.

The blood plaques are also to be considered, for in fever and other diseases they are always diminished. Their number is, according to Engel, in an inverse proportion to the number of leucocytes. Coagulation occurs before our eyes; we can see the fibrin filaments form. The red blood-cells soon form the well-known rouleaux; should this phenomenon occur only slowly or incompletely, or should it be absent altogether, we may be sure of having a grave disease of the blood before us. The size of the red blood-corpuscles is best measured in a fresh preparation. They differ considerably in size—in anæmia they have an average diameter of 6  $\mu$ : in a state of congestion, usually one of from 8 to 8½  $\mu$ . According to Limbeck, the red blood-cell in an artery is about one tenth of a diameter larger than that in a vein, from the absorption of oxygen, as he supposes. To me it seems much more probable that this is dependent rather upon the difference of the salty constituents or of the kind of salts in arterial and venous blood. An interesting experiment upon fresh blood is the determination of the resistance of the red corpuscles. This depends upon the facts that the red blood cells retain their hæmoglobin in serum and physiological salt solution, and that they yield their coloring matter to thinner salt solutions and distilled water. Very resisting blood-cells retain their hæmoglobin even in a four-per-cent. solution of salt, whereas weaker ones lose it in five-per-cent. solutions. The indifferent solutions are called isotonic.

The estimation of the blood-corpuscles by means of the Thoma-Zeiss camera is a method of investigation which, if carefully executed, gives very exact results. The older apparatus, such as those of Hayem, Gowers, and Malassez, have been more or less replaced by that of Zeiss.

\* Read at the scientific meeting of the German Hospital and Dispensary Staff, February 18, 1906.

I myself have no experience with any other. The principle which most of the gentlemen are acquainted with is very simple. In a pipette we dilute the blood one hundred times, count the sum of red and white blood-corpuscles in a measured volume of this mixture, and from this compute the number of morphotic elements in a cubic centimetre. The sources of error of this method have been discussed in a monograph by Reinert. It is most important that, in taking the blood, no pressure be exerted upon the finger, as otherwise lymph will exude from the wound, thereby diminishing the absolute number of red blood-corpuscles by from ten to twenty per cent. Alferow has photographed the blood-corpuscles, and thereby materially facilitated the counting. For general practice these and other more complicated methods are unsuitable. Eisholz has introduced a method of counting the leucocytes which, according to my experience, gives good results. Blood is sucked into the pipette up to the mark 1, then half of the bulb is filled with a watery solution of eosin-glycerin, and the rest of the bulb to the mark 101 with a solution of gentian violet. The red blood-corpuscles are dissolved by the glycerin, whereas the leucocytes take a differential stain, so that we obtain not only the absolute, but also the relative number of the different leucocytes.

Within a few years an instrument has appeared as a rival to the Thoma-Zeiss method, called the *hæmatocrite*. This was constructed according to the idea of Hedin, modified later by Gartner. This apparatus consists of a centrifugal machine in which two graduated capillary tubes filled with diluted blood are centrifugalized. These are graduated so as to allow the reading of differences of a hundred thousand red blood-cells. In the last few years several objections have been raised against the apparatus. The results, according to Friedheim, bear no relation either to the amount of hæmoglobin, or to the actual counting, or to the specific gravity, but are rather dependent upon the individual volume of blood-corpuscles. This varies in each individual, and changes, as Koppe has shown, with the degree of swelling of the blood discs. Although it must be conceded that the *hæmatocrite* is not very reliable in its results, yet Leopold Bleibtreu seems to me to be rather abrupt in his judgment in declaring it absolutely without value, and in wishing that it may rapidly disappear from medical laboratories. To me it seems to be sometimes of value to determine the volumes of the red and white blood-cells, and we can certainly draw at least preliminary conclusions from it. I have frequently used the centrifugal machine for separating the leucocytes from the blood. This method is almost indispensable, both for the examination of fixed leucocytes and for obtaining living ones for physiological experiments.

The average number of red blood-corpuscles in a cubic millimetre is estimated at 5,000,000. Women have rather fewer men somewhat more, the newly born usually about 6,000,000. The highest numbers—8,000,000 to

9,000,000—have been observed in congenital stenosis of the pulmonary artery (Bannholzer), the lowest—150,000—in pernicious anæmia (Quincke). The relation of the white to the red blood-corpuscles was given formerly as 1:300 to 600, now as 1:400 to 800, so that numbers below 400 and above 11,000 in a cubic millimetre are no longer to be considered as normal (Halla). Stricker fixes the maximum of the normal at 20,000.

The examination of the fixed cover-glass preparations has been perfected by more recent investigators, especially Ehrlich. The fixing serves to retain the shape of the cells, the granulations of the protoplasm, the structure of the nuclei, and the hæmoglobin. The latter is easily soluble, and is quickly extracted from the red blood-cell as soon as the protecting stroma has been altered. The surest way of fixing the hæmoglobin consists, according to Ehrlich, in long-continued heating up to 115° to 120° C. (in the hot-air stove or on a copper plate). The complicated albumins that are present as granules in the white blood-corpuscles are also fixed in such a manner that in staining they dissolve neither in the protoplasm of the cell body nor in the various fluids. The nuclear structure is also well preserved by the heat. Other fixing media are sublimate alcohol, alcohol and ether (equal parts), or a four-per-cent. solution of formaldehyde. Recently a mixture of one cubic centimetre of formalin and nine cubic centimetres of alcohol has been recommended. This mixture fixes in one minute, and the preparations are directly brought into the staining fluid. Ehrlich's dry method accomplishes at least just as much as the theoretically more correct method of fixing the blood in coagulating solutions, such as Flemming's chromosmioacetic acid, and subsequent imbedding and cutting.

We will now consider the blood-corpuscles separately, and commence with the red ones. Of the red blood-cells we distinguish those with and those without nuclei. Those without nuclei are called "cytes" by Ehrlich, the nucleated ones "blasts." To the "cytes" belong the erythrocytes, the normal ones; then the pathological forms, microcytes, macrocytes, giantocytes, according to their size, and poikilocytes according to their shape. The "blasts" are divided by Ehrlich into normoblasts (nucleated red blood-cells of normal size), microblasts, megaloblasts, and giantoblasts, and, if of irregular form, poikiloblasts. About the occurrence of the various forms we can briefly state the following: The erythrocytes are the elements of normal blood; microcytes are found in all diseased conditions of the blood, with anæmia regularly, in great numbers; they are absent, however, in chlorosis. Poikilocytes, as well as macrocytes and giantocytes, are always present in grave anæmias. Nucleated red blood-cells do not occur in the normal adult. With secondary anæmias we find usually only normoblasts; with primary anæmia, and especially its graver forms, the megaloblasts, giantoblasts, and poikiloblasts appear. In grave consti-

tutional diseases the red blood-cells are sometimes polychromatophile—i. e., they stain partly with acid, partly with basic dyes—a condition that is explained by some authors as a necrobiosis of the erythrocytes.

The leucocytes have been divided according to various principles. Usually they are distinguished according to the form of the nucleus and according to their size. We have (1) uninuclear leucocytes, including the small and large lymphocytes and the *cellules médullaires* of Cornil (2) polymorphously nucleated ones, and (3) multinuclear leucocytes. Of the uninuclear, the small lymphocytes are about as large as a red blood-cell, the large ones of twice the size, and both have a nucleus staining deeply with basic dyes. The nucleus of the *Markzellen*, on the other hand, has very little affinity for stains. The polymorphously nucleated leucocytes have a nucleus rich in chromatin and elongated, but narrow. This allows the cell to pass through the smallest openings. If this elongated nucleus divides into several nuclei also deeply tinged, we get a multinuclear leucocyte. Another method of classification is founded, according to Ehrlich, upon the granulation of the protoplasm. He found in many white blood-corpuscles granular albuminous substances that are chemically different from the protoplasm of the cell. These, according to their reactions, he divided into five groups, and called them the  $\alpha$ ,  $\beta$ ,  $\gamma$ ,  $\delta$ , and  $\epsilon$  granulations. According to more recent researches, the  $\beta$  and  $\delta$  granulations have been dropped, and we distinguish three kinds, according to their affinity for stains—acidophile, basophile, and neutrophile granules. We recognize the acidophile granules by the fact that, from a mixture of an acid and a basic aniline dye—e. g., eosin and methylene blue—they take up the acid one, whereas the basophiles stain with the basic one—e. g., methylene blue. The neutrophile granules, which would more correctly be called neutralophile, stain with the neutral salts of the aniline dyes and with neutral mixtures of acid and basic stains. Thus, a mixture of acid fuchsin and methylene green will tinge the neutrophile granules brownish red. In passing, we will remark that albuminates react toward acid, nucleins toward basic aniline dyes—i. e., albumin behaves like a base, the nuclear substance like an acid.

Practical medicine has unfortunately not gained very much by these color reactions. According to Arnold, a functional significance is to be accorded to the granules, but we can not judge of the origin of the particular cell by the kind of granulation. According to Zenoni, the granules may change in the blood from one form to the other.

Among the granulations, the acidophile especially has awakened great interest. The eosinophile cells occur in normal blood, and average one to five per cent. of the leucocytes. According to Swerschenski, Limbeck, and others, they are increased before an attack of asthma, and appear in the sputum. After the attack they are to be found only sparingly in the blood, whereas the neu-

trophile cells are increased. In malignant lymphoma we find them in great masses; in leucæmia their number is variable. A year ago I found in a leucæmic patient that nearly thirty per cent. of all the leucocytes showed eosinophile granulations; it is now several months since they disappeared and were replaced by non-granular and neutrophile *Markzellen*. Harmssen found in the blood of non-inflammatory hæmothorax, six days after an injury, almost exclusively eosinophile multinuclear cells. This would show that the eosinophile substance may be brought into some relation with hæmoglobin, all the more since Barker has shown in it the presence of iron.

As to the function of the granules, some light is thrown upon it by the paper of Martin Hahn, of Munich. Hankin and Kanthak have asserted that the antiseptic principle of the blood—alexin—is derived from the pseudo-eosinophile cells. Hahn was able to show that alexin was a nuclein derivative, and that it was secreted by living leucocytes, probably of the neutrophile variety. Increase of these leucocytes means also an increase of the antiseptic power of the blood. Pawlowsky succeeded in immunizing rabbits against infection by pneumococci, by exciting leucocytosis by means of injecting papayotin. Loewy and Richter obtained the same results by injecting spermine. If the results of Hahn are confirmed, it remains to be shown which leucocytes contain most of the costly substance alexin. Then the insurance companies will not only look for albumin and sugar, but also for the bactericidal cells of the blood.

A comprehension of the various cell forms named above is only possible if their genesis is known. In the embryo, blood is made long before spleen, lymph glands, and bone marrow have become distinct. At first, large multinuclear cells rich in hæmoglobin are found, from which partly vessels, partly the so-called metrocytes (Engel), are developed. The metrocytes multiply by mitosis, and divide finally into an erythrocyte of the first degree (a megalocyte) and a megaloblast. The latter, again, divides into an ordinary erythrocyte and a nucleated cell, called an erythroblast, or leucoblast, according to whether hæmoglobin is present in the plasma or not. This cell, however, may also disintegrate at once and form a collection of blood plaques. These I, together with Howell, consider as the fragmented nuclei of leucocytes. Lowitt declares them to be precipitated globulin; Bouchet calls them the building stones of the red blood-cells. Mondino and Sala assert that the blood plaques multiply by karyokinesis. The leucocytes develop later in the embryo than the red blood-cells. They originate in the lymph-forming organs which Ziegler designates as parts of the mesenchyme with an embryonal character. The leucocytes, with the exception of the multinuclear, probably belong to the lymph, and are found in the blood as well as in some other organs. In the adult blood-formation goes on in the same way as in the embryo, with the exception that the ery-

throcytes are primarily developed from the bone marrow, secondarily from the spleen. I am sorry that I must refrain from entering upon other theories of the genesis of blood. From this it will be clear that the diseases of the organs forming the erythrocytes are to be strictly distinguished from those of the organs generating the leucocytes. How the different pathological conditions are to be classified as underproduction or overproduction on the part of the blood-forming organs we are as yet unable to decide; and we must not attribute all anomalies of blood composition to these organs. A primary change in the blood may produce an increased destruction of white or red blood-corpuscles. This, again, by charging the blood with the products of destruction, especially of the white blood-cells, would excite an increased formation of leucocytes. The relative number of blood-corpuscles in normal blood seems to be maintained by the fact that destruction and new formation bear an intimate relation to one another. If many leucocytes die, the plasma will contain many nuclein acids and bases, which again are the best means to increase the number of leucocytes threefold in a few hours. If many red ones are destroyed, or oxidation is lessened, a need for oxygen will arise in the bone marrow, and with this perhaps a stimulus to cell division, for the generation of erythrocytes is inversely proportional to the amount of oxygen in the air. Jaruntowski and Schroeder, Mercier, and other authors have carefully studied the relation of the number of blood-corpuscles to the elevation. The higher the latter, the greater the first. A few hundred metres (corresponding to a drop of three and a half to four millimetres of mercury) make an appreciable difference in the number of blood-corpuscles. An artificial lowering of the atmospheric pressure by eighty millimetres produced in animals an increase of seventeen per cent. of the number of red blood-cells and an increase of twenty-five per cent. of the amount of hæmoglobin. If you consider that on the sea level variations of the barometer of sixty to seventy millimetres of mercury are possible, you must assent if I assume that the number of erythrocytes always varies considerably with the barometer. Even if the differences amount only to from three to ten per cent., yet they must make themselves felt, and they explain perhaps the feeling of malaise that many people experience when the barometer falls—an increased need of oxygen of the tissue cells, and consequently an abnormal irritability of the ganglia.

If we consider the blood from a chemical standpoint, we must always keep in mind that all the tissues of the body are permeated by this vital fluid, and that every organ contributes its share to the composition of the fluid blood. Therefore any functional disturbance of a single organ will, to a very great extent, change the constituent parts of the blood. Thus it is evident that diseases of the liver, lungs, kidneys, heart, and digestive organs have a most powerful influence on the blood.

The plasma—i. e., the fluid blood—consists of serum and a fibrinogen substance. Unfortunately, the time at our disposal precludes a consideration of the minutiae of the blood, and I must therefore refrain from a consideration of the pathological admixtures, such as those of bile acids, bile pigments, sugar, glycogen, urea, uric acid, etc. Besides being present in serum, glycogen has been found in leucocytes, and, according to Livierato, quite frequently in pneumonia. In chronic diseases the amount of albumin in the serum is proportionate to the nutritive changes of the body; the poorer the nutrition, the less will be the amount of albumin. The latter is, however, increased in all acute febrile diseases. But in practice the determination of the amount of albumin is a process altogether too complicated to be of immediate diagnostic aid.

The most important of all chemical blood examinations is the determination of the percentage of hæmoglobin. The earlier methods are antiquated (Hayem, Bizzozero), and only the apparatus of Fleischl, that of Gowers, and perhaps that of Henoque remain in use. There is no lack of careful and minute articles on the methods of ascertaining the percentage of hæmoglobin. Most authors give preference to Fleischl's apparatus; not a few, however, such as Lederer, Osterspey, Noorden, and Honigmann, recognize Gowers's apparatus. I myself am in the habit of using Gowers's hæmoglobinometer, and I believe the sources of error are not much greater than in Fleischl's apparatus. The hæmatoscope of Henoque permits not only of a direct reading off of the specific gravity, but also of a spectroscopic determination, which to an experienced eye will perhaps yield the best results. The apparatus has furthermore the advantage that any modifications of the hæmoglobin, the reduced hæmoglobin, and methæmoglobin will be recognized. I shall at this time not enter upon any more detailed account, but proceed to the determination of the specific gravity. Stintzing has given a practical and pretty exact method. He places about five drops of blood on small glass plates of a known weight, and with an accurately fitting cover. He then weighs the drops of blood while fresh, and again after drying for twenty-four hours. From the difference in weight he determines the amount of water. In the same manner the specific gravity of the serum is determined after obtaining the pure serum by means of centrifugalizing blood which has been deprived of its fibrin. Normal blood contains seventy-eight to seventy-nine per cent. of water; pathological blood up to ninety per cent. In chlorosis and leucæmia the solid residue is less diminished than in anæmia. It is noteworthy that in healthy individuals an abundant consumption of water has hardly any influence on the specific gravity of the blood. The majority of authors entertain, in opposition to Schmalz, the opinion that albumin, hæmoglobin, and the amount of water are by no means always in the same proportions to each other, so that no inferences can be drawn from one to

the other. The comparative examinations thus far made will probably in the near future enable us to compile tables by means of which the chemist will be in a position to diagnose certain blood diseases. Thus a fundamental difference between chlorosis and simple anæmia becomes manifest by the fact that in chlorosis, with sixty per cent. of hæmoglobin, there exists considerably more solid residue than in anæmia with the same amount of hæmoglobin. In chlorosis the blood contains more red blood-cells than in anæmia with the same amount of hæmoglobin.

The methods of the quantitative determination of the alkalinity of the blood have lately been subjected by Loewy to thorough investigation. He finds that titrations yield unreliable results, inasmuch as the chemical union of the acid and the bases contained in the blood-cells takes place too slowly. He therefore first renders the blood lake-colored by means of glycerin. The most difficult task is to recognize when sufficient of the reagent has been added to produce the desired reaction. In this connection the method employed by George W. Jacoby and myself is perhaps the easiest. The method has been described in Pfüger's *Archiv*. In uræmia, cholera, and poisoning by acids the alkalinity of the blood is considerably diminished. In sulphuric-acid poisoning the reaction of the blood is even said to become acid.

The study of the coagulability of the blood affords us an insight into one of the most important vital processes. Owing to the labors of Kossel and his pupils, the study of this subject has made great progress. In the year 1892 Alexander Schmidt compiled a work on the study of the blood to which he had devoted his whole lifetime. In this work he modifies considerably his old theory. His new doctrine is so complicated that it is almost incomprehensible. Schmidt has since died, but he lived long enough to witness the tottering of the beautiful structure which he had raised, and he became a silent spectator of the entirely different and happy inroads made by younger investigators. Since his death a further addition to the study of the blood has been published, embodying many interesting ideas, but nothing specially new. The creators of the new and probably lasting doctrine of the coagulability of the blood are Hammarsten, Arthus and Pages, Pekelharing, Kossel, and Lilienfeld. Hammarsten has shown that the fibrino-plastic substance is not essential to the coagulability of the blood, but that the fibrinogen ferment and a soluble calcium salt alone are essential. If the latter is precipitated by means of sodium oxalate, then, according to Arthus and Pages, the blood can not coagulate. Pekelharing found that the fibrin ferment was an organic combination of lime in which the lime had an affinity for the fibrinogen. The theory of Lilienfeld is as follows: The nuclei of the leucocytes contain a complicated albuminous body, nucleohiston, which is composed of a basic, peptonelike, albuminous body, histon, and an acid nucleoproteid, leuconuclein. The substance histon im-

pedes the coagulability, whereas leuconuclein induces it. If the leucocytes disintegrate, the acid leuconuclein becomes dissolved, and unites with the fibrinogen to form thrombosin. The latter forms in combination with lime salts the typical fibrin. Thus we see that fibrin is a combination of nuclein acid, fibrinogen, and lime. Out of the leuconuclein substances (the latter belong in the realm of the nuclein acids) are formed, after trivial chemical changes, the xanthin bases. These are the forerunners of uric acid. Neusser has been able to demonstrate these xanthin bases in the blood of gouty patients. He found numerous uninuclear lymphocytes with basic granules, and he considers these granules to be the disintegrated products of the nuclein. On account of this, and especially on account of the experiments conducted by Richter, the theory of gout has assumed a different aspect. Horbaczewski's theory, which considers uric acid to result from the disintegration of leucocyte granules, seems to be confirmed. Weintraud was enabled to support this theory in a most beautiful manner. He gave a man two pounds of thymus a day (the thymus contains a considerable amount of nuclein), and he observed that the amount of uric acid rose from half a grain (normal) to two grains and a half a day. The number of leucocytes was in this case not correspondingly increased.

Let us consider more carefully the various diseases whose diagnosis and prognosis depend upon an examination of the blood, or which can at least be influenced by it. I have reference to anæmia, leucocytosis, leucæmia, and diseases showing specific blood parasites.

The various forms of anæmia may be caused by a primary diseased condition of the blood-forming organ, of the bone marrow, or by a diseased condition of any other organ which indirectly affects, by its nutritive disturbance, the activity of the bone marrow; or the disease may be produced by the destruction of the red blood-cells. If many of the latter are destroyed, then, according to well-established physiological laws, will their production be increased. Even a sort of compensatory hypertrophy of the bone marrow may be brought about. If this is the case, many immature forms of red blood-cells will enter the circulation. We then find in the blood these immature bodies in the form of macrocytes and microcytes, various erythroblasts, which exhibit at times mitosis—indeed, at times even giant cells containing hæmoglobin. These forms are signs of regenerative attempts; we are, however, by no means in a position to infer from these forms the kind of anæmia that exists. All they indicate is the degree of anæmia. In slight anæmia they are almost entirely absent, so that we can regard only the diminution of the hæmoglobin and of the number of red blood-cells as a general characteristic of anæmic blood.

As regards the various forms of anæmia, Hofmann distinguishes anæmia caused by hæmorrhage, anæmia caused by inanition, chlorosis, and primary pernicious

anæmia. In acute anæmia caused by hæmorrhage the regenerative changes are absent. We simply find a diminution in the amount of hæmoglobin and the number of erythrocytes. This circumstance might be made use of in forensic medicine. Anæmia of inanition admits, unfortunately, of no distinction from anæmia caused by nutritive disturbances. Many attempts have been made to discover microscopical and chemical differences in the blood in cases of anæmia secondary to carcinoma, tuberculosis, and kidney and intestinal diseases. Few facts, however, are to be regarded as definite. Ziemssen finds in chronic parenchymatous nephritis the amount of hæmoglobin always considerably diminished; in chronic interstitial nephritis, however, either normal or increased. In carcinoma ventriculi no increase of leucocytes is said to take place during digestion, whereas in ulcer ventriculi leucocytosis is never lacking. In tuberculosis without fever the blood is nearly normal; in carcinoma, however, the specific gravity, the albumin, and the amount of hæmoglobin, as well as the number of red blood-cells, are diminished. The behavior of the leucocytes in those forms of anæmia which we have mentioned is very variable. The number may be diminished; sometimes, however, there may also exist leucocytosis.

Chlorosis occupies a separate position. It is characterized in part by very pale and quite often somewhat small red blood-cells, hardly diminished in number, and in part by a relatively large diminution in the amount of hæmoglobin. The number of leucocytes is usually normal, and poikilocytosis is absent. Primary or so-called pernicious anæmia consists in extreme diminution of the amount of blood, and in extreme deterioration of the quality. The diagnosis of primary anæmia can not be made with certainty from an examination of the blood alone. Still, an impoverished condition of the relative elements of the blood, in the absence of changes in other organs, enables us to suspect the condition quite early. In true primary anæmia a small movable parasite has often been found in the blood in the form of a glöbule  $1\frac{1}{2}$   $\mu$  in diameter, called *Cercomonas globulus*.

We have yet to regard those diseased conditions of the blood in which an absolute increase of the leucocytes forms the most prominent feature—namely, leucocytosis and leucæmia. These two diseases differ fundamentally, and not in degree only. In the incipient stages leucæmia might be mistaken for leucocytosis, although the actual number of leucocytes usually decides the diagnosis. In leucocytosis we find 15,000—at the most 80,000—leucocytes; in leucæmia, from 50,000 to 400,000 and more. Still, the principal difference is to be attributed to the forms of the leucocytes. The multinuclear cells alone are increased to any appreciable extent in leucocytosis, whereas in leucæmia they occupy a subordinate place as compared with the so-called "Markzellen," which latter are absent from the blood under almost all other conditions.

Leucocytosis, according to my opinion, is always to be regarded as an actual increase of the multinuclear leucocytes circulating in the blood. Nevertheless, according to Goldscheider and Jacob, leucocytosis may be mistaken for transitory changes in the distribution of the leucocytes. These transitory changes in the number of leucocytes—for instance, after an injection of turpentine alcohol—are most probably accounted for by the supposition that these leucocytes remain in a certain isolated territory of the circulation. The seat of origin of the multinuclear cells is the bone marrow, in which they are always to be found in great numbers (Ehrlich, Zenoni). The sudden migration of these cells into the blood circulation seems to be dependent upon a nervous influence on the vessels of the bone marrow. Certain chemical products which enter the blood lead to a specially marked leucocytosis. Thus we find above all the albuminous bodies of the nuclein series and the poisons emitted by bacteria, such as ptomaines and toxalbumoses, creating a marked leucocytosis. Digestive leucocytosis is probably caused by an absorption of the digestive products, whereas in carcinoma leucocytosis will occur only when, through disintegration of a large number of cancer cells, nuclein products are reabsorbed. Whether the multinuclear cells which arise in the blood as a final product of the mature processes of lymphocytes are identical with those that have their origin in the bone marrow remains yet to be demonstrated. Both forms of leucocytes seem to exhibit neutrophile granules.

Limbeck and others have found that leucocytosis is especially prevalent in those infectious diseases which are accompanied by an exudate. This applies above all to purulent, and also to fibrinous, exudates. In the case of "croupous pneumonia" leucocytosis runs about parallel to the fever and spread of the local signs. The more marked the leucocytosis is in relation to the infiltration, the more favorable is the prognosis. With the beginning of the crisis, the number of leucocytes diminishes. If a relapse occurs, the number again increases. In the early stages of typhoid fever there is at times a slight leucocytosis; as a rule, however, the leucocytes are diminished in number as in malarial disease. It is therefore not difficult to distinguish from an examination of the blood between pyæmia and pneumonia, on the one hand, and typhoid and malarial fever on the other.

The study of leucæmia has lately been very much simplified by A. Fraenkel. He discards the old distinction between myelogenic, lymphatic, and splenic forms of leucæmia, for leucæmia is a general disease of the lymph-cell-forming organs, of the lymph apparatus, of the spleen, and of the bone marrow. He recognizes two forms of leucæmia—namely, lymphocythæmia and leucæmia with Cornil's *cellules médullaires*. True lymphocythæmia, as a rule, runs an acute course, but there are also acute forms with a preponderance of *cellules médullaires*. In the chronic forms the cells have time to become granular. Quite often there is a division of

the nuclei of the *cellules médullaires*—a process which is purely of a degenerative nature, and not at all concerned with the formation of multinuclear cells. The importance of the various cells becomes manifest in the following histological consideration: The lymph follicle consists of a pulp and a cortex. The pulp—Flemming's germinative area—is composed of large cells with large, slightly reticulated nuclei in continual active division. The cortex consists of smaller cells, with nuclei rich in delicate reticular network. These nuclei also exhibit many forms of karyokinesis. The former cells correspond to the so-called *cellules médullaires*, which are not at all concerned with the marrow. The latter are the more mature lymphocytes. Under the influence of the leucæmic toxins, they either obtain an excessive proliferation of the cortical cells, which will then flood the blood with lymphocytes, or else a proliferation of the cells of the germinative area. In the latter case the *cellules médullaires* will enter the blood. Highly interesting is the retrogression of leucæmia in septic infection. The examination may yield entirely negative results, so that only leucocytosis can be diagnosticated—i. e., the multinuclear leucocytes displace the uninuclear ones. After the infection has been successfully combated, then these leucæmic cells reappear. As the therapy is absolutely hopeless in these cases, the injection of toxins might be indicated in order to check the cell proliferation, the same as in sarcoma.

Owing to lack of time, I am obliged to abstain from a consideration of the bacteriological blood examination. Let us devote but a few words to Laveran's malaria plasmodia. They are found in the red corpuscles as pigmented protozoa in continual motion. In the stained specimen various forms may be recognized, and the several types of malarial disease distinguished accordingly. The patient ought not to receive any quinine before the examination is made. By means of thorough massage, the plasmodia are said to enter the circulation (Weir Mitchell, Jr.) They are most readily found in the splenic secretion. The examination for malaria plasmodia, unfortunately, consumes considerable time. This may serve as an excuse for administering quinine tentatively. Quinine diminishes the number of leucocytes, and has a deleterious effect upon diseases with leucocytosis. In those diseases it is contraindicated.

We may regard with great satisfaction the latest advances made in hæmatology, yet we must not for a moment lose sight of older investigators, who, with poorer equipments but great intellect, forty or fifty years ago, erected single pillars of this structure, whose completion concerns so many men even at the present time.

Virchow described leucæmia in 1845. His account of the cells is in such striking conformity to our modern ideas that I should like to quote a few sentences: "The cells which I had found were mostly colorless, granular cells, of various diameters. Some had apparently no

nucleus; instead of that, however, a large number of small granules in their interior [these latter we call at present eosinophile cells]. Others had a single round nucleus; others, again, had a flask-shaped nucleus or several nuclei. [The latter correspond to our multinuclear cells.] In some few cells smaller granules were found [neutrophile cells]." Even though Virchow did not use these names, he nevertheless recognized the difference between eosinophile, neutrophile, multinuclear, and uninuclear cells.

100 EAST FIFTY EIGHTH STREET.

## SOME POINTS IN THE TREATMENT OF IMPERMEABLE STRICTURE OF THE URETHRA.

ILLUSTRATED BY FOUR CASES.

REPORTED BY J. S. WIGHT, JR., M. D.,  
BROOKLYN.

SOME patients with stricture of the membranous urethra, fearing operation, neglect to seek the advice of the surgeon. When they are finally obliged to ask assistance, a careful examination shows the stricture to be impermeable. The following cases, operated on by Professor Wight at his clinic at the Long Island College Hospital during the session 1895-'96, will illustrate some points on the treatment of impermeable stricture:

CASE I.—John J., aged forty-two years, was admitted to the hospital October 28, 1895, suffering from retention of urine. At fourteen years of age he had gonorrhœa. For the last ten years he had had trouble in urinating and consulted no one till two days previous to admission to hospital, when his bladder had to be aspirated to give him relief. His physician sent him to the hospital. He was suffering exquisite pain in the hypogastrium, though his bladder was not much distended. No guide could be introduced and aspiration failed to draw off urine. He was given hot baths and later the urine dribbled away. He was given a grain of opium the next morning and another attempt made to enter the bladder, which failed. All subsequent attempts were equally unsuccessful. Perineal section was performed on November 6th, as follows: A lithotomy staff was passed to the stricture; an incision was made through the perineum to the beak of the staff; then a long, straight bistoury was used, cutting through the indurated tissue, along the line of the normal location of the urethra, till the point entered the neck of the bladder; a grooved director was passed through the incision into the bladder and the retained urine ran out; the finger of the surgeon was passed along the groove of the director into the bladder and the strictured portion dilated. Saline irrigation was then used, and a large catheter introduced into the bladder through the perineal wound and retained in position, dressings were applied, and the patient put to bed. Oozing was considerable till the next day, and the dressing had to be repeatedly changed. On the second day following the operation he was taken with severe chills and vomiting. The next day he had severe pain in the right gluteal region, with swelling and slight, deep fluctuation. An aspirating needle drew off a small quantity of bloody serum with escape of gas. That evening he was put under an anæsthetic and a free incision

made through the right gluteal muscles. There was considerable inflammation of the surrounding tissues with some foetid pus. The wound was washed out with a solution of bichloride of mercury and dressings applied. The next morning he was jaundiced and in collapse. He died at 9 A. M. of acute pyæmia. No autopsy was performed.

CASE II.—George C., aged thirty-two years, was admitted to the hospital November 8, 1895, suffering with retention of urine. He had gonorrhœa six years ago followed by stricture. Sounds were passed for a time, and being relieved he neglected further treatment until four years ago, when he had retention, and then the stricture was dilated. Though he had some difficulty in passing water, he saw no physician till six weeks prior to admission to the hospital. A guide was with difficulty passed into the bladder. The stricture again closed down tightly and he came to the hospital with the urine dribbling away from overdilatation. No guide could be introduced. He was given hot baths and put on a grain of opium a day. Three days later a small whalebone guide was passed through the stricture into the bladder. Two days later perineal section was performed, as in Case I. The bladder was allowed to drain through a catheter in the wound, and the dressing changed daily for the first week. The catheter was then taken out, and straight Nos. 15 to 20 American sounds passed through the perinæum into the bladder and also through the pendulous urethra. At the end of five days curved sounds were used. This was continued daily, patient passing less and less urine through the perineal opening till December 14th, when there was a small granulating surface left, and all the urine passed through the urethra. He left the hospital, and I saw him from time to time till the middle of March. I then passed a No. 19 American sound with ease. The wound was entirely healed and urination was painless and free.

CASE III.—Pat M., aged thirty-two years, was admitted to the hospital November 25th, suffering with retention of urine. He had gonorrhœa fifteen years ago. For the last two years he had urinated with difficulty and had learned to pass sounds on himself. About a year and a half ago an abscess formed in the perineum discharging through the urethra. On examination, the bladder was found to be greatly distended. A small whalebone guide was introduced into the bladder through a false passage. Perineal section was performed two days later, as in Case I. An abscess cavity was found in the perinæum, and passing through it and running toward the right ischial tuberosity into the bladder was the guide, which was left in during the operation. This was taken out, and the operation completed as in Case I. The next day the catheter came out and was put back with difficulty. This man was an epileptic, and when the catheter was taken out a week later, an attempt to pass sounds caused convulsions. It was not for several days, and until the opening had closed for an inch along the pendulous urethra, that he could in any way tolerate sounds. The opening into the bladder remained patent. I cocaineized the pendulous urethra and forced a straight sound through. The wound continued to granulate, but the convulsions prevented the proper use of sounds. He was finally anesthetized and a No. 20 American passed. He afterward submitted to their use with more regularity. The wound healed rather slowly, and he left the hospital January 14th, with only a very small sinus left in the perinæum.

CASE IV.—Mr. T., aged forty-five years, was admitted

to the hospital December 20, 1895, suffering with a retention of urine. He had had gonorrhœa seventeen years ago followed by stricture, which he had neglected. A small guide was passed, and the retained urine came away in a very fine stream giving relief. The guide was fastened in, but slipped out later, and all attempts to enter the bladder again were futile. Perineal section was done the next day, as in Case I. The patient was very weak, and it was necessary to hurry the operation, the point of the bistoury entering the neck of the bladder and urine escaping in five minutes from the time of the first incision. There were a number of strictures in the anterior urethra, which were cut with a narrow bistoury on a grooved director from the perineal wound so as to admit a No. 20 sound. A rubber catheter was placed in the pendulous urethra in addition to the one in the bladder. The catheter was removed from the pendulous urethra on the fourth day and straight sounds passed; the other was removed from the bladder at the end of a week and curved sounds passed. The wound healed slowly, and the patient deserted January 6, 1896, with very little urine passing through the perineal wound.

### THE TREATMENT OF SOME TRAUMATIC LESIONS OF KNEE JOINT.

By J. O'CONOR, M. A., M. D., B. CH., TRINITY COLLEGE, DUBLIN,  
SENIOR MEDICAL OFFICER, BRITISH HOSPITAL, BUENOS AIRES.

HEMARTHROSIS.—F. M., aged sixteen years, a groom, was admitted into the British Hospital on the 27th of February, 1896, suffering from a large swelling of the left knee-joint. Three days previously, while exercising a polo pony, he was thrown off and, falling on to some stones, received a contusion of the left knee; he was able to get up and limp home. His parents, seeing that the articulation was considerably swollen, applied cold-water dressings; the patient noticed that the pain was in no way proportionate to the amount of distention.

Two days later he was brought to the hospital; the leg was placed on a McIntyre splint, and, as the joint was considerably distended, aspiration was performed; two ounces of blood were withdrawn, but as the cannula became plugged with clots the joint could not be properly emptied.

On the following morning, as the distention was as much as before tapping, the skin having been thoroughly disinfected, chloroform was administered, and an incision an inch in length made parallel and half an inch internal to the inner border of the patella. On the capsule being opened some five ounces of blood gushed out, followed by clots; the index finger was introduced into the synovial pouch and many adherent clots detached, and removed by irrigation with a 1-in-40 warm carbolic lotion. A gauze drain was inserted and the wound dressed with iodoform gauze and sublimate wool.

First evening, temperature normal, no pain or discomfort. On the fourth day the dressings were changed and the drain removed, the joint appeared quite dry. On the seventh day three silkworm-gut sutures were inserted and the wound was closed; on the eighth day the patient moved his joint through an angle of forty-five degrees; while so doing, some synovial fluid escaped from the wound.

On the twelfth day voluntary movement beyond a right angle was possible without pain. On the fourteenth day the sutures were removed as they were caus-

ing some skin irritation. The patient was allowed out of bed on the nineteenth day and was walking about the garden twelve days later with a normal joint.

My reasons for operating were: First, the presence of such a large amount of clotting blood in the joint; secondly, a strong prejudice against allowing any accumulation of blood to remain in or about a wound, be it external or internal; and thirdly, the certainty that the operation could be carried out aseptically.

To young men entering the curriculum of life it is without doubt a handicap to leave a collection of clotting blood in their knee-joints in the hope that Nature may remove it; we know that the liquid portion probably may be absorbed, but we also know that clots tend to form adhesions, and thus the future utility of the limb runs a great risk of being permanently impaired.

Again, in those whose constitutions are below par, I consider early operation all the more imperative, for an enfeebled body means diminished vitality of the tissue cells, consequently a weakened home defense; a collection of stagnant blood or serum at the normal temperature of the human body provides an excellent medium for the cultivation of the lower forms of organic life; and pathogenic microbes possess the faculty of working their passage from outside, through the blood, to habitations that may be suitable for the propagation of their species; with these premises it may be, at any rate, logically concluded that the removal of the medium before the coccus arrives is expedient surgery.

In carrying out this object, two instruments are useless—a trocar and cannula; the latter is liable to get plugged with clots, then evacuation of even the fluid blood is impeded; fibrinous coagula in the recesses of the synovial pouch are not removed, as was shown in the above-cited case—nothing short of digital shifting sufficed; and when the fluid pressure within the joint is suddenly diminished, fresh hæmorrhage may take place from the ruptured capillaries; if so, we are left *in statu quo antes*.

An incision possesses the following advantages: Thorough elimination of all blood and clots; digital examination, whereby any adhering clots may be removed; the arrest of hæmorrhage, if necessary, by gauze packing, and rest is provided for the injured synovial membrane by a more prolonged drainage; also the over-stretched ligaments are afforded a chance of promptly and permanently contracting to the normal.

**FRACTURE OF THE PATELLA.**—During the past year I opened the knee-joint on four occasions in order to wire transverse fractures of the patella; in each instance the first thing noted was the large amount of blood clot present; next, the constant overlapping of the fragments by the torn prepatellar aponeurosis; and lastly, the amount of oozing that followed refreshing of the broken surfaces. The deductions that naturally followed were, that in all fractures of this bone there must be a considerable quantity of blood effused into the

joint—consequently, a great probability of many adhesions forming, if such an amount of clot is left; that any attempt to unite the fragments without removing the fibrous tissue that overhangs the broken surfaces must be futile so far as perfect bony union is concerned; and lastly, that the apposition brought about by wire sutures does not in all cases arrest the oozing from the revivified surfaces, and there is a chance, if drainage is not provided for, that a fresh collection may take place. Consequently, any operation undertaken for the adjustment of the fragments scientifically and practically necessitates evacuation of all blood and clots, excision of the overlapping fibrous tissue, and prevention by drainage of any subsequent accumulation. Lister's operation fulfills the first two requirements, but not the third, which is equally important, and is best effected by a loose roll of iodoform gauze. This drain may be left in with safety until the fourth day, and the wound united on the seventh by two or three silkworm-gut sutures.

I shall now briefly mention what I consider a most important detail in the after-treatment of traumatic injuries to this joint. A surgeon of such world-wide reputation as Mr. Watson Cheyne recommends early passive motion (I believe within the first week) in cases of fracture of the patella. I confess I have often puzzled over the rationale of such a practice, and I can not arrive at any other conclusion than that its object is to prevent blood clot forming adhesions; for with the limb extended and carefully bandaged on to a straight back splint, undue contraction of the flexors can not be apprehended; if a collection of serum or thickening of the synovial membrane is feared, I do not see how early movement is going to help; and it is presumed that no rheumatic, gouty, or other tendency is present. On the other hand, to start active motion (I use the word active, for I generally have found the muscles, laryngeal included, anything but passive) at a time when we know that bony union has not taken place, and when the traumatic irritation of the surrounding structures can not possibly have subsided, is, in my opinion, a dangerous performance, and likely to bring about the very things that are so essential to avoid—continuance and increase of inflammation, a parent of stiff joints. I think it might be laid down as a fairly safe rule, in the majority of cases of traumatic arthritis, that movement by the patient's own muscles should form the advance guard to any movements by the surgeon.

**ACUTE SYNOVITIS.**—T. T., aged thirty-eight years, stevedore, while working in a ship's hold on January 19, 1896, received a contusion of his right knee by a bag of maize falling on it; he immediately felt pain in the joint, but foolishly continued at his work until the 21st, when, owing to the swelling and pain, he could not stand it any longer. On the 29th of January he was admitted into the hospital. The joint was distended with fluid, patella floating, and he complained of pain on the slightest movement; calor well marked.

The limb was placed on a pillow, which was fixed by sand bags, and a Martin's elastic bandage applied; this treatment was continued for four days without any marked benefit. Three blisters of Scott's dressing and a splint were substituted, and this was continued for three weeks, at the end of which, tumor, dolor, and calor had disappeared; a few days later he was placed in an easy chair beside the bed, with an elastic bandage on the knee; as no relapse followed, five days later he was told to cautiously put his foot to the ground (of course, crutches having been provided). This he did; on the following morning the joint was found in the same condition as on the day of admission to hospital.

It was now determined to incise and drain; and the most scrupulous attention was paid to the disinfection of the limb, hands, instruments, etc. On the 9th of March an incision an inch and a half in length was made parallel to the inner border of the patella, over the most bulging spot, and three ounces of serum and synovial fluid were evacuated; the index finger was then introduced into the synovial pouch, and, as no very marked thickening of membrane was found, a few strands of iodoform gauze were inserted and iodoform gauze dressings applied.

As the temperature did not exceed 99° the dressings were not changed until the fourth day, when they were found soaked with synovial fluid; no pus; a gauze drain was again inserted. The wound was dressed daily for the following three days; by the eighth day all excessive secretion had ceased, and on this date the patient voluntarily and painlessly moved his joint through a right angle. On the thirteenth day four silkworm-gut sutures were inserted and the wound closed; these were removed on the twentieth day, as firm union had taken place; the splint was left off on the twenty-second day and he was allowed to sit up in a chair for one hour. On the twenty-fourth day he walked to the garden with the aid of two sticks; no swelling, pain, or heat followed; on the thirty-sixth day he walked out of the hospital without a limp, normal movement having been completely restored.

Since January 1st three other cases of synovitis of the knee have been treated in a similar manner with equally good results.

Splints, ice-bags, hot irons, blisters, leeches, etc., without doubt served surgery well at a time when pus followed the knife as surely as night follows day; but under the existing conditions of surgical cleanliness there can be no excuse for continuing their service beyond a limited period. And I should think there were very few surgeons who could conscientiously say that the long-continued expectant treatment of this affection was satisfactory, and that the ultimate results paid for the time lost. I will now take the liberty of quoting from Mr. Barker's most excellent treatise in Treves's *System of Surgery*. In describing the treatment of acute synovitis, this gentleman states:

"In many cases, too, where there is much tension from effusion, aspiration of the joint with a sterilized hollow needle is the readiest way of giving relief, and this should be done before the capsule and ligaments have been overstretched, and the synovial membrane permanently altered." Under prognosis: "But when the measure has been too long delayed the synovial

membrane becomes thickened and shrunken and has lost its elasticity and smooth surface, and the subsequent movements of the articulation are permanently impaired."

In this most able appeal for early surgical intervention I most heartily concur, but differ as to the method; for I consider a small incision with gauze drainage infinitely preferable to the use of a grooved needle. By the former no re-accumulation of fluid can take place, as sometimes happens after the latter; the synovial membrane can be examined, and, if any part of it should be very much thickened, it may be excised; rest is assured to the joint for as long as the surgeon chooses, whereas after aspirating it is in some cases only momentary; again, the puncture of a needle may in itself cause hemorrhage into the joint.

If this latter objection should appear far-fetched, let the unbeliever open up some of the wounds that he has just sutured, and he will be astonished at the amount of bleeding on the inner surface that occasionally follows the puncture of a needle, which, if untreated, furnishes a suitable nidus for a wandering microbe. And I think it may be truly said that the gauze drain is to the medium as Listerism to the germ and that the elimination of both germ and medium is an absolute aseptic necessity.

In conclusion, I feel convinced that we should be acting in a manner more becoming, both to our art and to the interests of our patients, if we would only consider ourselves above the sphere of criticism that may emanate from sources infected with septic superstitions, and open the joint in every case of simple traumatic synovitis, which had not yielded (disappearance of excessive fluid) to twenty-one days' thorough expectant treatment; by so doing, permanent thickening of the synovial membrane may be prevented, and many patients saved from having a weak knee for the rest of their lives.

In carrying out this simple operation the most scrupulous cleanliness must be adopted, and the routine which I now employ may serve, in some degree, as a guide to others. The day prior to operation the limb is shaved, scrubbed with soap, and hot soda water; then sponged with turpentine and a piece of antiseptic lint wrung out in 1-in-500 bichloride solution wrapped around the joint and fixed on for the night by sublimate wool and a bandage. The patient having been chloroformed, a nurse removes this dressing with a sterilized scissors and forceps. The field of operation is again sponged with turpentine and washed with 1-in-500 bichloride solution; the thigh and leg are enveloped in towels that have been boiled and soaked all night in 1-in-500 bichloride solution; the same are placed all round so that if an instrument is left down on the table it can not be infected. (All instruments are previously boiled.) The hands and arms having been scrubbed with soap and soda water, are placed for two minutes in a basin of Watson Cheyne's strong lotion. An incision from one to

two inches in length is made parallel to and half an inch internal to the inner side of the patella; as the structures are divided, all bleeding points are secured; when all oozing has ceased, the capsule is seized with a dissecting forceps and opened; two pressure forceps are applied, one on either side, to the cut edges of the capsule, with a flat sponge. External pressure is made directly over the synovial pouch; by this means all the fluid is gently squeezed out. The index finger is next inserted, and, if any thickened tags of synovial membrane are found, they are seized with a torsion forceps and excised. If any hæmorrhage follows this latter procedure a small sponge on a pressure forceps is introduced and direct pressure made; at the same time, external pressure with a large, flat sponge is carried out as before; in this way the bleeding is soon stopped. Three or four sterilized silkworm-gut sutures are inserted through the whole depth of the incision, including the capsule (by the forceps previously placed on the incised edges this can be accurately done); they are tied loosely, and ample space left for the introduction of a few strands of iodoform gauze into the synovial pouch. Iodoform is dusted freely all round and the dressing consists of iodoform gauze and sublimate wool. A McIntyre splint is applied; this is fixed above and below the wound with domette bandages.

The dressings and drain are removed every two days, and if on the seventh day the secretion of synovial fluid has decreased to normal, the edges are united by the silkworm-gut sutures already inserted. These are removed on the fourteenth day, and, if the union is firm, the patient is allowed out of bed on the sixteenth with instructions to daily increase the range of movement. No knee-cap or elastic bandages are applied; these can be profitably relegated to the limbo of unreliable trusses and fantastic pessaries.

In this age of asepticism, to sentence an unfortunate breadwinner to a term of two, four, or six months on splints or on the broad of his back, for water on the knee, is to my mind an unjustifiable and unsurgical procedure, and, as Mr. Arbuthnot Lane very tersely remarks, writing on the treatment of simple fractures, "The commercial value of a limb nowadays deserves the serious consideration of every surgeon."

As the struggle for existence became more keen, it seems as if Nature had risen to the occasion, and brought forth a Lister to propound the art of antiseptics, in order that the full physiological activity of wounded limbs might be so speedily restored that their owners might not be compelled to drop out of the race and become candidates for parish relief.

**The Fifteenth Annual Announcement of the New York Post-graduate Medical School and Hospital** has just been issued. It appears that five hundred and forty-two physicians have attended the courses at the institution during the past year, and that more than a thousand operations were performed in the hospital.

## Therapeutical Notes.

**Arsenic in the Treatment of Gastralgia.**—In the *Lancet* for July 4th Sir James Sawyer, M. D., of Birmingham, says: "Further observation in practice has confirmed my favorable opinion of the curative efficacy of arsenic in the various painful neuroses included under the name gastralgia. I have already laid before the profession my earlier experience in this subject. Romberg's well-known description of gastralgia is classical. He distinguished two forms of the malady—gastrodynia neuralgia, which he held to be hyperæsthesia of the gastric branches of the pneumogastric nerve, and neuralgia coeliaca, which he attributed to hyperæsthesia of the solar plexus. Clinical experience confirms the views of Niemeyer and of Henoch that this distinction is difficult and of doubtful utility in practice. Gastralgic affections, severe and slight, are rare in hospital practice, and frequent among private patients, especially in those of nervous temperament. I need scarcely observe that for obvious reasons the diagnosis of gastralgia is one which should neither be lightly made nor negligently maintained. But pain arising in the stomach when the organ is empty and relieved by the ingestion of food is almost diagnostic, as the late Dr. Wilson Fox taught, of its nervous nature and origin. With due regard to the causal concomitants and antecedents of gastralgia arsenic cures the disease. It is best to give the drug in a pilular form. I exhibit a twenty-fourth of a grain of arsenious acid made into a pill with two or three grains of some tonic vegetable extract, such as gentian, three times daily halfway between meals. Scarcely any other medicinal treatment is needed in cases of moderate severity and the use of the remedy should be continued for some weeks. In severer cases I use counter-irritation to the epigastrium of duly proportioned activity. I have usually found a full and varied dietary suit gastralgic patients far better than a restricted 'dyspeptic' regimen. It is in such cases that Trousseau's maxim is so true—that we should know what a patient does eat before we advise him upon what he may feed."

**Glycerin in Certain Affections of the Stomach.**—In the same article, Sir James Sawyer remarks that some years ago Dr. Sydney Ringer recommended the administration of glycerin by the mouth in certain affections of the stomach. Acting upon his suggestion, he has since treated many cases of painful gastric digestion, such as are usually attributed to subacute or chronic catarrh of the gastric mucous membrane, with glycerin with satisfactory results. So far as he has seen, this employment of glycerin is not widely extended in professional practice, and he has not noticed further reference to it in the periodicals. The familiar routine seems to be a ringing of changes upon bismuth, alkalies, acids, and digestives. Many cases of gastric maladies of the kind indicated yield to glycerin; he gives a drachm, a drachm and a half, and sometimes even two drachms, with a little of some simple bitter stomachic tincture, diluted to an ounce with water, thrice daily, between meals.

**A New Physician Extraordinary to the British Queen.**—The *Lancet* announces that Dr. Samuel Wilks has been appointed one of Her Britannic Majesty's physicians extraordinary.

THE  
NEW YORK MEDICAL JOURNAL,

*A Weekly Review of Medicine.*

FRANK P. FOSTER, M. D.

NEW YORK, SATURDAY, JULY 25, 1896.

POTATO POISONING.

IN the July number of the *Centralblatt für die gesammte Therapie* there is a condensed account, from the *Archiv für experimentelle Pathologie und Pharmacologie* and the *Correspondenz-Blatt für schweizer Aerzte*, of an investigation into the proportion of solanine contained in potatoes under various circumstances. The inquiry was undertaken apropos of certain cases of poisoning among French and German soldiers attributed to potatoes. It seems that in 1892 three hundred and fifty-seven men of the garrison in Alsace were seized, one after another, with frontal headache, severe colicky pains in the stomach and bowels, vomiting, diarrhoea, prostration, and moderate stupor. In a few cases there were pallor of the face, blueness of the lips, great dilatation of the pupils, brief faintness, and acceleration of the pulse followed by its retardation. In the severer cases there was a rise of the temperature to from 101° to 103° F. In only one case was there collapse, and in that it was of brief duration. In the course of ten days all the men were well. Not long afterward ninety men of another garrison belonging to the same army corps were attacked with similar symptoms, and in 1893 a hundred and eighty-six men belonging to a battalion of infantry and to one company of another battalion were taken with vomiting and diarrhoea, together with great weakness, abdominal cramps, and pains in the back and limbs, but without dilatation of the pupils. Although the cases at first seemed severe, they all ended in speedy recovery. A few years before, the same symptoms had occurred in a division of the Lyons garrison and been attributed to eating bad potatoes. While it was chiefly new, unripe potatoes that were eaten in Alsace, the French soldiers ate old ones that were sprouting.

From the chemical investigation made to clear up these cases it appears that potatoes that are fresh and have not sprouted contain, from November to February, from 0.04 to 0.046 per cent. of solanine, and, when peeled, only from 0.02 to 0.025 per cent. Old potatoes that have sprouted, in the period from March to July,

may contain from 0.08 to 0.116 per cent. of solanine. When potatoes had been made to sprout artificially and the sprouts were about a tenth of an inch long the chemist found 0.212 per cent. of solanine. The alkaloid is especially plentiful in the sprouts themselves; in a sprout a third of an inch long he found about five per cent. of it, but it decreases with the growth of the sprout, so that in one a little over three inches long he found only 2.7 per cent. Especially significant were the examinations of spoiled potatoes. Those that were withered and softened were found to contain 0.144 per cent. of the alkaloid. In a piece a year old, black internally and beset with fungi, 1.34 per cent. of solanine was found. Sound potatoes containing 0.043 per cent. of solanine were inoculated with the fungous growths, and at the end of two months, although but few of the inoculations had proved effective, they were found to contain 0.08 per cent. of the alkaloid. The dwarf potatoes produced by sprouting in the cellar were found particularly rich in solanine, containing as much as 0.52 per cent. The conclusion was reached that potatoes must contain an exceptional proportion of solanine to be poisonous, and be old, withered, or sprouting.

THE RESUMPTION OF WORK AFTER PARTURITION.

THE Paris Society of Public Medicine and Professional Hygiene was lately fretted for the third time with the discussion of a proposition to seek for legislation restraining working women from resuming their occupation within less than four weeks after their confinement, or at least providing for their maintenance for that length of time at the public expense in case of need. M. Dion, who insisted on the measure, reminded his hearers that three years before a legislative committee had asked M. Pajot, the president of the Obstetrical Society, if it was dangerous for a woman to engage in an industrial occupation within four weeks after having given birth to a child, and the society had unanimously answered in the affirmative. M. Dion conceded that there would be difficulty in fixing the rate of indemnity, so only the following resolutions in general terms were submitted to the meeting: 1. That the public authorities should make provision for assuring to lying-in women a rest of four weeks before resuming industrial work. 2. A maternity fund should be created in each commune, to be maintained at the expense of both the commune and the nation.

M. Poitou-Duplessis, in the name of personal lib-

erty, violently opposed the idea of regulating such a matter by law, but M. Langlet, whose name is appended to the report of the meeting published in the *Presse médicale* for June 27th, suggests that the speaker must have forgotten that all measures of public hygiene necessarily rested on constant violation of individual liberty, and he gives as instances compulsory vaccination, the declaration of infectious diseases, and the enforcement of disinfection. The reporter further points out that M. Poitou-Duplessis was particularly unfortunate in holding up England as furnishing an example to be followed, for England was the first country to regulate labor by law in the interest of hygiene.

Another gentleman protested on different grounds. In his opinion, it was useless to insure a woman four weeks of rest after confinement; she should rest for two months before parturition and for at least six weeks after it. This proposition, says the reporter, being absolutely impracticable, can have had only one purpose, that of causing the vote to be adverse to every prophylactic measure. The report closes with the statements that the meeting was far from agreed on the subject and that the resolutions were passed by a bare majority.

Leaving entirely out of view the political and economic aspects of such a question, and they seem to us highly important, one may safely say that some such course as the resolutions favored would be of great value from the hygienic point of view. We are not prepared, however, to say that the period of four weeks' rest is either necessary in the majority of cases or sufficient in those in which it is really needed, but as a minimum requirement it would doubtless do some good.

### MINOR PARAGRAPHS.

#### A CONGENITAL CHORDA TENDINEA IN THE AORTA.

DR. RÖHRLE (*Deutsche medicinische Wochenschrift*, 1896, No. 17; *Deutsche Medizinal-Zeitung*, July 2, 1896), in the post-mortem examination of a child that had died of ileo-colitis at the age of two weeks, recently found a tense tendinous cord in the aorta. It arose from the junction of the left end of the left semilunar valve and the left end of the posterior semilunar valve, and extended to the junction of the left end of the right semilunar valve and the other end of the left semilunar valve. The reporter remarks that such an anomaly does not seem to have been described before.

#### "LE ET LES"

A STORY is going the rounds of the French journals to the effect that a Chinaman, being hard pressed for money, sat down and cut off "le et les," thereby making himself a cunuch. He sold "le et les" for nine francs,

or perhaps it would be more correct to say that he pawned them, for of course they had no intrinsic value, but were taken in the belief that their original owner would eventually seek to redeem them in order to present himself in the next world "complete." It is said that as large a sum as \$3,000 has been paid for the redemption of "le et les."

### ITEMS.

**Infectious Diseases in New York.**—We are indebted to the Sanitary Bureau of the Health Department for the following statement of cases and deaths reported during the two weeks ending July 21, 1896:

DISEASES.	Week ending July 14		Week ending July 21	
	Cases.	Deaths.	Cases.	Deaths.
Typhoid fever.....	17	7	25	4
Scarlet fever.....	51	8	59	3
Cerebro-spinal meningitis...	6	4	3	5
Measles.....	194	14	151	11
Diphtheria.....	221	36	191	29
Tuberculosis.....	95	90	172	95

**A New Sanatorium in Ontario.**—Dr. Edward Playter, whose book on *Consumption* we lately noticed, has opened a new sanatorium, called Sydenham House, in Ottawa, also, at King's Plateau, in the Gatineau Hills, ten miles away, a branch known as Sydenham Cottage. The situation in the hills is described as being about midway between the Atlantic Ocean and the great lakes, more than a thousand feet above sea level, and with a dry, sunny, and most invigorating atmosphere. Dr. Playter announces that he will give special attention to the treatment of pulmonary consumption in its early stages, to the treatment of heart diseases by the Schott method, and to the cure of obstinate cases of rheumatism, neuroses, and other conditions that can not be managed to advantage at the patients' homes.

**A New Hospital in Springfield, Massachusetts.**—The House of Mercy hospital was opened for patients on July 14th. It has thirty beds and is in charge of the Sisters of Providence. While the gentlemen of the staff are all members of the Massachusetts Medical Society, paying patients in private rooms may be attended by their own physicians of any school. Dr. D. E. Keefe is president of the medical staff, and Dr. C. H. Calkins secretary.

**A Spurious Tokay.**—The *Deutsche Medizinal-Zeitung* quotes from the *Süddeutsche Apotheker-Zeitung* a statement to the effect that the Bavarian newspapers are warning their readers not to buy a so-called medicinal Tokay furnished by the Düsseldorf firm of Albert Fuchs & Co. An official examination has shown that this product has none of the distinctive features of genuine Tokay.

**Army Intelligence.**—Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from July 12 to July 18, 1896:

EWEN, CLARENCE, Major and Surgeon. The leave of absence on account of disability granted him is extended one month.

WORTHINGTON, JAMES C., Major and Surgeon. The extension of leave of absence on account of sickness granted him is further extended one month.

**Navy Intelligence.**—Changes in the Medical Corps of the United States Navy for the Week ending July 18, 1896:

DICKSON, S. H., Surgeon. Ordered to the U. S. Steamer Texas.

FARNHOLT, A., Assistant Surgeon. Detached from the U. S. Steamer Monterey and ordered to the Mare Island Hospital, California.

LARRIS, H. N. T., Passed Assistant Surgeon. Ordered to the Pensacola Navy Yard, Florida.

MOORE, J. M., Assistant Surgeon. Detached from the Naval Hospital, Norfolk, and ordered to the U. S. Steamer Texas.

PERSONS, R. C., Surgeon. Orders to duty at the Naval Hospital are revoked, and he is ordered to continue on present duty.

#### Society Meetings for the Coming Week:

TUESDAY, *July 28th*: Richmond, Virginia, Academy of Medicine and Surgery; Medical Society of the County of Putnam (annual), N. Y.

WEDNESDAY, *July 30th*: American Microscopical Society of the City of New York; Medical Society of the County of Albany, N. Y.

THURSDAY, *July 30th*: New York Orthopædic Society; Pathological Society of Philadelphia.

### Births, Marriages, and Deaths.

#### Married.

ALDRICH—HART.—In the City of Lake Charles, Louisiana, on Wednesday, July 15th, Dr. R. H. Aldrich, of Baton Rouge, and Miss Gertrude Hart.

#### Died.

HOLDER.—In Memphis, Mississippi, on Wednesday, July 15th, Dr. A. B. Holder.

MACKENZIE.—In Negaunee, Michigan, on Monday, July 13th, Dr. A. C. Mackenzie.

RING.—In New Haven, on Friday, July 17th, Dr. Frank Whitman Ring, of New York, in the forty-eighth year of his age.

### Letters to the Editor.

#### MEDICAL EDUCATION IN ILLINOIS.

952 MILWAUKEE AVENUE, CHICAGO, July 13, 1896.

To the Editor of the *New York Medical Journal*:

SIR: In your *Journal* of the 11th inst. I find an article by Dr. Daniel Morton, of St. Joseph, Mo., on the Future of Medical Colleges in the Smaller Cities of the United States, which I have read carefully.

One can not help but agree with the writer of the exhaustive article as regards his criticism of the defective medical education in this country in past years. His suggestion to establish "State examining boards" in all the States of the Union is probably the best solution to the perplexing question of medical education in this country.

The doctor's views on the superiority of medical colleges in large cities are not, however, quite in accordance with the facts. Allow me to state that upon careful investigation he will find in the city of Chicago, besides the three regular medical schools that maintain a high standard, a number of inferior evening colleges of medicine, the purpose of their existence being to defeat the spirit of the medical practice act, though they profess to comply with the letter of the law.

These evening colleges of medicine grant diplomas after an attendance varying from six months to four years, which the State board of health recognize. Upon the payment of five dollars and the presentation of such a diploma, the State board of health of Illinois grants applicants a license to practise medicine and surgery in the State of Illinois.

Dr. Morton in his article makes mention of the State

board of health of Illinois, under the leadership of Dr. John H. Rauch, as having been the pioneer in the regulation and control of medical practice in the United States, whose efforts resulted in the establishment in several States of the "diploma law." The deceased Dr. John H. Rauch, who was the secretary of the Illinois State board of health for several years, certainly well earned the esteem in which he was held by his brother physicians and all those who knew of him, for he was a man of integrity and honesty of purpose and an industrious worker in the interests of progress. He did more for the medical profession than a dozen State boards of health combined.

It is this very same State board of health—but now with another secretary—that enables colleges like the Harvey and Harvard night schools of medicine to do a thriving business by inducing young and middle-aged men and women to leave the workshop and the stockyards where they slaughter cattle, for the more remunerative occupation of slaughtering mankind.

But, it may be remarked, these men must produce evidence of preliminary education and comply with the other requirements of the law before they enter a medical school. As long as the enforcement of those rules rests with the school and not with the State board, the law is easily enough evaded. The Harvey night school of medicine is satisfied with a statement, made before a notary public, that the applicant has the necessary qualifications to study medicine, though his examination papers prove that he has not mastered the first rudiments of grammar, and words found in the First Reader are misspelled.

This school, as well as others of the same character in the city of Chicago, allows its students to work all day at their respective occupations, and exacts of them an attendance upon lectures three hours evenings, namely, from 7 to 10 P. M., although excuses of three months' absences are accepted.

As for clinics, they receive mention in the *Catalogue*, and students graduate without ever having seen a single capital operation at the college, there being no hospital connected with it, and but few dispensary clinics.

The facilities of the school are of the most limited kind. It is located on a floor and a half of an office building, where there are a dentist, a private dispensary of an advertising doctor, and a good-luck store. One can form an idea of what kind of material they can get up there for the benefit of evening students.

It is not hard to imagine what an amount of knowledge can be acquired by an untutored student, after having done a hard day's labor in the workshop, in three hours evenings, with such facilities for instruction. And yet the State board of health recognizes this school.

The secretary of the college sends circulars to factories and workshops offering to make doctors of all comers at the nominal fee of sixty-five dollars annually, to be paid during the year in installments of ten dollars a month.

In what a deplorable state of confusion must the medical education of such a student be when he graduates, and yet his diploma is equal before the law to that of his neighbor who is a graduate of a good medical college and who has spent years of study and undivided attention in the acquirement of the fundamental facts upon which the science and practice of our profession are based.

Two such manufactories of doctors are already recognized by the State board of health; a third one—a so-

called summer school, the Illinois School of Medicine—has been promised recognition next year.

Does this present such a bright picture for the future of medicine?

In the State of Illinois there are no recognized schools of midwifery. Every midwife must undergo a thorough examination before the examining board of the State. This means that the afflux of so-called midwives to the State is somewhat checked, as a large percentage of those applying for a license fail to pass their examination. Just now there is a movement afoot to recognize certain schools of midwifery and to do away with the State board examinations.

The present secretary of the State board of health is a warm supporter of that movement. Only a short time previous to this application for recognition—which will surely be granted—the previously mentioned Harvey night school of medicine established a branch school, the so-called Playfair School of Midwifery, in which male and female midwives are to be manufactured. Does this look very much like progress?

The remedy, of course, lies with the medical profession. As long as State boards are created by politicians only, and the regular profession ignored in the matter of selecting the members of those boards, so long will they respond to political and other influences and license quackery.

I am glad to know that several States of the Union have already established examining boards, and that the members of such boards are chosen from a list or lists presented to the governor of the respective State.

The foregoing was written with the hope of stimulating an expression of opinion on the part of those practitioners of medicine who have the progress of medicine at heart and who annually find themselves surrounded by their tailors, shoemakers, and grocery clerks, all ready to shake hands with them as colleagues in their peculiar transformation from shoemaker to doctor—and yet these very same physicians are prevented by a false sense of modesty from raising their voices against the frauds perpetrated against the public health and the medical profession in the name of law.

JULIUS GRINKER, M. D.

## Proceedings of Societies.

### AMERICAN ASSOCIATION OF GENITO-URINARY SURGEONS.

*Tenth Annual Meeting, held in Atlantic City, on Tuesday and Wednesday, June 2 and 3, 1896.*

The President, Dr. CLAUDIUS H. MASTIN, of Mobile, in the Chair.

**The President's Address.**—The speaker briefly reviewed the history of the association since its organization in 1886. He stated that during the past ten years great advances had been made in the field of genito-urinary diseases. The various organs which were comprised in its domain had been studied and thoroughly investigated. Our knowledge of their pathology and of the therapeutic measures required for their treatment had each been systematized. Our instruments of investigation had been improved and new ones had been

invented; the technics of our operations had been simplified and perfected. The kidney and the bladder, together with the organs of generation, had been opened up and illuminated; the hidden recesses of the entire system had been exposed to the eye, so that no longer were we groping in the dark, but, aided by all the means of modern research, our diagnosis of hitherto obscure troubles had been cleared of doubt. Some of the greatest minds of past ages had done much in the department of genito-urinary diseases, and through their investigations it had been recognized as of the greatest importance. The immortal John Hunter had understood its bearing upon scientific medicine, and indelibly impressed his great name upon the very keystone of modern pathology, the hard chancre. His researches in this line had blazed out the pathway of our present knowledge of syphilis.

**Five Cases of Rupture of the Urethra treated by External Urethrotomy and Suture.**—Dr. A. T. CABOT, of Boston, read a paper with this title. He stated that the intractable nature of traumatic stricture of the urethra was so well known that no apology was required for the following report of some cases in which an attempt had been made by immediate suture of the ruptured urethra to furnish accurate coaptation of the divided ends of the canal, and, by promoting rapid and smooth healing of the mucous membrane, to avoid the formation of stricture. Hitherto, the latter had been regarded as an inevitable consequence of a urethral rupture, and while in the fortunate cases of moderate severity the regular passage of a sound might keep the urethra permeable, neglect of this precaution might be expected to result in a rapid closure of the stricture. In other cases of greater severity the stricture showed a constant tendency to contract in spite of every effort to keep it open, and repeated operations were required to avert the serious consequences of a complete closure. Dr. Cabot then described five cases of traumatic rupture of the urethra which had been treated by immediate external urethrotomy and suture. In all the cases the immediate result of the operation had been good. In three of them the opportunity had been given for examination some years after any dilating instrument had been used. In two of these cases no stricture had been found and instruments as large as those which had been used immediately after the operation, or even larger, had slipped past the point of rupture with perfect ease. In one case, while no interference with urination had been noticed, a narrowing of the urethra had been found; this narrow point, however, had not been of a hard, cicatricial nature, but so soft and yielding that without the least exercise of force it had been rapidly dilated to a good size.

The conclusions of the author were as follows: 1. In every case of ruptured urethra, immediate perineal section, with suture of the urethra, should be practised. 2. By this procedure not only was the danger of urine infiltration and abscess greatly lessened, but in a large proportion of cases the prevention of the formation of close, intractable strictures might also be hoped for. 3. In the early operation, the search for the posterior end of the urethra was much easier than in the later. The hemorrhage from the branch of the artery of the bulb served as a guide to that end of the canal.

Dr. J. WILLIAM WHITE, of Philadelphia, said that he fully concurred with Dr. Cabot in the general principles laid down in his paper. There was another class of cases, however, in which it was sometimes difficult to decide just what procedure to follow—namely, cases of slight injury

in which there were practically no symptoms except a little hemorrhage and, perhaps, some perineal swelling. In a slight, partial rupture of this character, was the outlook from suturing any better than could be expected from the introduction and retention of a large-sized instrument and careful urinary antiseptics?

Dr. JOHN P. BRYSON, of St. Louis, said he was entirely in accord with the statement made by Dr. Cabot that an early operation was demanded in a case of traumatic rupture of the urethra. If it could be demonstrated that the lesion in the urethra was transverse or oblique, the indications were to open and suture it. In these cases there was often a semilunar laceration to be dealt with.

Dr. F. R. STURGIS, of New York, said that when the rupture was slight, the introduction of an instrument to keep the canal patent was often all that was necessary. When, on the contrary, the rupture was extensive, an operation was called for.

Dr. ABNER POST, of Boston, reported a case of ruptured urethra which had recently come under his observation. In this case, the speaker said, the patient would have been better off had an immediate operation been performed and the urethra sutured.

Dr. GEORGE CHISMORE, of San Francisco, said that, while he coincided with the views of the writer of the paper in every respect, yet it seemed to him that it was a little premature to conclude that a rupture of the urethra, not sutured and left to the healing powers of Nature alone, would invariably lead to a particularly intractable form of stricture. He reported a case in which he had had an opportunity to examine the urethra of a patient who had sustained a traumatic rupture of the canal ten years before, in whom no instruments had been passed for many years. He had found a stricture at the seat of the injury which had yielded very readily, admitting within two weeks a No. 10 French.

Dr. BRYSON said that in the linear form of stricture, which was usually a simple band rising quite sharply from the urethral wall, dilatation would often produce good results and sometimes bring about a radical cure. A longitudinal tear might heal even without the use of a catheter, but in traumatic cases the rupture was usually transverse or oblique.

Dr. CABOT said he agreed to the statement made by Dr. White that it was often difficult to decide whether a patient required immediate operation or whether milder measures would suffice. The feeling he had was that if a patient who required early operation was not operated on, bad results usually followed, such as an abscess, together with a cicatricial stricture, which might have been avoided by an immediate operation. The actual danger pertaining to such an operation was trivial. It was a much more serious matter if a blood clot or a tear was left in the mucous membrane. In case of doubt, therefore, it was well to operate. There were undoubtedly cases where the injury was so slight that such treatment as had been indicated by Dr. White would suffice, but where there was inability to pass a catheter, or if there was a large swelling in the perineum, an operation was necessary. In the case related by Dr. Chismore, the good result had been, no doubt, partly due to the fact that a perineal opening had been made, thus preventing urinary infiltration.

**Two Cases of Urethrotomy, with Transplantation for Urethral Strictures.**—Dr. JOHN P. BRYSON, of St. Louis, related the following case: The first patient was seen by him in December, 1891. He had an annular stricture of the urethra the anterior face of which was situated five

inches and a half from the meatus. The stricture had its origin in a gonorrhœa contracted eight years before. It was of the inflammatory variety, resilient, and had repeatedly resisted efforts at dilatation carried beyond No. 14 French. Having been convinced that further palliative treatment was useless, the speaker said he had opened the canal on December 22, 1891, and had disclosed a stricture about a quarter of an inch in breadth situated at the posterior part of the bulbous sinus, and lined by roughened and inflamed mucous membrane. There had been no well-defined margin between the healthy and diseased tissues, the one gradually shading into the other. The membranous portion of the urethra had not been much dilated, but had been in a state of mild, chronic, purulent inflammation. The urgent request of the patient, who had demanded a radical cure of the trouble which had considerably undermined his health, had led Dr. Bryson to disregard the additional risk caused by the posterior urethritis, and at once to dissect out the whole of the diseased tissue, going well beyond it on either side, in order to be sure of the mucous membrane. When the dissection had been complete it had been seen that the divided ends of the urethra had been separated fully three quarters of an inch and an attempt to bring them together had failed. As the base of the wound had been composed of spongy and vascular tissue, immediate transplantation of a graft taken from the lining membrane of the prepuce had been ventured upon. This had been stitched to the cut ends of the urethra by interrupted catgut sutures. The urethra and bladder had been thoroughly irrigated with warm carbolic-acid solution, a catheter which passed the full length of the urethra had been tied in, and the perineal wound had been propped open with iodoform gauze, loosely placed. On December 24th the gauze had been removed; two days later the catheter had been removed, and on inspection it had been found that the graft had "taken." The catheter had been left out. The patient had passed his urine chiefly through the perineal incision. He had left the hospital on January 6, 1892, at which time the perineal wound had almost closed. He had come under observation again in March, 1894, complaining of a free urethral discharge, and after this had been cured a No. 30 French sound had entered the bladder easily, almost painlessly, and had caused no bleeding. On December 26, 1894, the patient had reported that he had had no further trouble and had been able to urinate in a full stream. He had again been heard from in the fall of 1895, when he wrote that he had remained perfectly well since the operation and could urinate in a full stream at normal intervals, and that he had had no treatment in the interim.

In the second case several attempts at transplantation had been made before a successful graft could be introduced.

(To be continued.)

## AMERICAN SURGICAL ASSOCIATION.

*Annual Meeting, held in Detroit on Tuesday, Wednesday, and Thursday, May 26, 27, and 28, 1896.*

The President, Dr. LOUIS McLANE TIFFANY, of Baltimore, in the Chair.

(Concluded from vol. lxi, p. 786.)

**Intrathoracic Tuberculosis.**—In a paper on this subject Dr. GEORGE RYERSON FOWLER, of Brooklyn, went into the historical part of the disease at great length,

and devoted considerable attention to the surgical treatment of pleuritis and empyema. Of all the organs in the human body, he said, the lungs were most frequently the seat of tuberculosis. Inasmuch as there was no lung affection that might not be complicated by tuberculosis, it followed that pleural affections were most frequently tuberculous in character. Few patients who had suffered from pleurisy escaped tuberculosis, and this fact increased the importance of the surgery of pleuritic affections in their relation to tuberculosis.

The author gave a brief account of the effects of pleuritic effusion upon the progress of tuberculous disease of the lungs. The view formerly held, that the activity of the circulation in the lung tissue constituted a trustworthy means of protection against the occurrence of tuberculous infection of the respiratory organs, was combated. The application and technics of exploratory puncture or thoracentesis, incision, and drainage, König's operation, and the resection of a portion of rib were gone into quite extensively. This was followed by a consideration of the operation of thoracoplasty and its indications. Schede's operation of extensive resection of the chest wall, including, with the bony resection, removal of the attached soft parts, namely, the intercostal muscles and thickened pleural membrane, was described. It was recommended that the edges of the incision be approximated closely about the drainage tube and the dressing applied in such a manner that the tube should pass through them. The drainage tube was then to be attached to a tube which was sufficiently long to lie over the side of the bed and touch the surface of a sublimate solution. When the patient could sit up, the tube was to be fastened to a bottle at the waist, as suggested by Bulau, of Hamburg. By this method of drainage the patient was saved from the discomfort produced by soiled dressings.

The question of complications occurring in connection with thoracoplastic operations upon the chest wall, namely, pulmonary thrombosis and cerebral embolism with the resulting paralysis, was alluded to.

The consensus of opinion at the present day seemed to discountenance thoracotomy in tuberculous patients, preference being given to repeated puncturing or, at the most, the method of permanent siphonage.

As to the direct treatment of tuberculous cavities, it was stated that some difficulty must necessarily be experienced in the selection of proper cases. In cases in which the disease had come to a standstill, any interference would be unjustifiable, for the reason that it was these cases in which a cure was obtained by natural processes.

The operation of resection of the lung was discussed at some length, and attention was called to the fact that the pulmonary structure differed from all other structures in the body in its susceptibility to infection and its anatomical peculiarities.

The experiments of Gluck, of Berlin, and Hans Schmidt upon the lower animals in resection of the lung were detailed, as also those of Virondi, who had produced localized tuberculosis in the lower animals.

**Tuberculosis of the Superficial Glands.**—Dr. DEFOREST WILLARD, of Philadelphia, detailed the method of tuberculous infection of the lymph nodes. The route of entrance was usually by very slight abrasions or injury. Slight wounds were more likely to admit bacilli, as they aroused local resistance to a lesser degree than severer injuries. The face and neck were especially common places of entrance. The lymph glands acted

as filtration stations, and often proved effective in overpowering the invading foe. An individual's resistive force might be lessened by hereditary impairment of cells or by the temporary condition of the tissues. Local caryocinetic action might be effective, or, if only partially, caseation and absorption might occur with less resistive power, or, if staphylococcus infection resulted, suppuration followed. When once the glands had become infected, they were a perpetual menace to the general system, and should be removed. Suppuration would sometimes effectually destroy all the invading bacilli; yet this was a slow and dangerous process, subjecting the individual to constant risks. Infected glands should be removed if possible during the stage of induration. The removal of tuberculous glands from the neck was frequently a most serious operation, provided connective-tissue infiltration was present, and especially if the chain of glands had dipped deep beneath the cervical vessels and nerves or had extended below the clavicle. These deep glands could be safely removed only by following the line of cleavage between the gland and the protection wall, which had been partially thrown about it, each gland being cautiously shelled out. The jugular veins, the branches of the carotids, and the pneumogastric and phrenic nerves should be carefully avoided. When a vein was injured, immediate pressure with subsequent ligation or lateral suturing should be performed. If the phrenic or pneumogastric was injured, it should be at once sutured with fine silk. Great care should be exercised to prevent the discharge of pus and caseating material upon the fresh wound; if such an accident occurred, the area should be thoroughly cleansed and disinfected. Temporary drainage was advisable when infection had occurred from such a discharge, but with clean enucleation primary union without drainage could be secured. In infection in the axilla, the glands should be enucleated with the same care that was employed in the removal of carcinomatous nodules. The same rule held good in regard to glands situated in the arm. In the groin many difficulties would be encountered, especially if the indurated glands extended deep about the femoral or saphenous vein. Secondary operations were advisable, if necessary. In patients who absolutely refused operation, local and constitutional measures must be employed, including the use of tuberculin and serum therapy. Dr. Willard had more confidence in the local effects of iodine upon tuberculous granulations than in those of iodoform. He had also obtained beneficial results by stimulating cell growth with a mixture of aristol and nuclein or protonuclein, applied locally. Infiltrated glands should not be allowed to remain and contaminate the general system.

**Does Additional Experience show that Castration is a Curative Remedy in the Treatment of Hypertrophy of the Prostate Gland?**—Dr. ALBERT T. CAROT, of Boston, read a paper in which he expressed the following conclusions: 1. In the matter of mortality the operation of prostatectomy had a slight advantage over castration. It seemed probable that, with later statistics which reflected the last improvements in the technics of prostatectomy, this advantage would be further increased. 2. Prostatectomy had the further advantage that it allowed of a thorough examination of the bladder and of the discovery and correction of other conditions not before suspected. Stones were frequently removed in this way without adding to the gravity of the operation. In several reported cases of castration the absence of improvement had led to the subsequent discovery of stones which

had required other operations for their removal. 3. Prostatectomy had, on the other hand, the disadvantages that it confined the patient for a longer time, and that it was sometimes followed by a fistula. This had occurred in one of the forty-two cases cited by the author. 4. It was too early to know whether any permanent loss of vigor followed castration when done on old men. The nervous effects which sometimes immediately followed the operation suggested a suspicion that with the testes the system might lose some tonic effect which was exerted by those organs. 5. The functional results of the two operations seemed at present to be as nearly equal as possible, and the tendency to relapse showed itself in about the same proportion of cases after either operation. 6. The reduction in the size of the prostate after castration was largely due to a diminution of congestion. Later, a degeneration and absorption of considerable portions of the gland might occur. The glandular elements were particularly affected by this atrophy. 7. Castration would seem to be especially efficacious in cases of large, tense prostates when the obstruction was due to pressure of the lateral lobes upon the urethra. 8. Castration was of but little use in myomatous and fibrous prostates. 9. Prostatectomy had its special field in the treatment of obstructing projections which acted in a valvular way to close the urethra. There was, however, no form of prostatic obstruction which a skillful operator might not correct by prostatectomy. 10. Prostatectomy was, then, applicable to more cases than castration and was especially to be selected when an inflamed condition of the bladder made drainage desirable.

Dr. J. EWING MEARS, of Philadelphia, had been very much struck with the mortality shown from the different operations. He was sorry to learn that no one had any information to offer concerning an operation which had been suggested by himself as a substitute for castration—namely, ligation of the vas deferens.

Dr. CHARLES B. NANCREDE, of Ann Arbor, said that, as a result of his work with the operation of castration, he had been converted from a rather doubtful attitude toward the operation to a desire and willingness to do it again. He gave at some length the details of a case in which he had operated. The patient had done very well after the operation, but had died in five or six weeks from an infection of the wound.

Dr. L. P. PILCHER said that from the statistics mentioned in Dr. Cabot's paper it would seem that prostatectomy had a slight advantage over castration, not only in its results, but also by affording opportunity to secure relief from other urinary complications at the time of operation. In his own hands, however, all prostatectomy operations had been failures, but if the opinions of other surgeons could be ascertained, it would probably be found that a much larger proportion of fatal results really occurred than the figures mentioned by Dr. Cabot showed. The operation of prostatectomy had been resorted to only in cases of men who had manifested considerable vigor, while, on the other hand, castration had been performed on patients who were already extremely feeble and could not stand a more serious operation, and frequently by surgeons who were not particularly expert in genito-urinary work.

Dr. J. McFADDEN GASTON, of Atlanta, spoke of a method of treatment that had recently been brought to his notice the principle of which was to endeavor to reduce the size of the prostate by the employment of prostatic extracts in a somewhat similar way to the methods now employed with the thyroid extract.

Dr. ROSWELL PARK, of Buffalo, mentioned two cases of castration performed by himself in which the subsidence in the volume of the prostate gland had been remarkably rapid and complete. In his opinion there could not be a simpler or easier operation.

Dr. ROBERT ABBE, of New York, spoke of a case in which he had removed both testicles under cocaine, with the result that the prostate had been reduced more than half its size. He compared the operation of castration to that of removal of the ovaries.

Dr. CABOT said that the most important question was, not as to the ability of the operator, but as to the selection of the proper cases for the operation of castration. If a proper selection was made, he believed the mortality would be greatly reduced.

**The Ambulatory Treatment of Fractures of the Lower Extremities.**—Dr. LOUIS S. PILCHER, of Brooklyn, mentioned a large number of cases of fracture in which the ambulatory treatment had been employed, and illustrated his paper with diagrams of the apparatus employed. He described in detail the manner of applying the plaster bandage so as to form a sufficiently rigid and protecting case, and also explained the splints used in this method of treatment. He stated that the number of cases of fracture of the leg which had been treated by himself up to the present time with the ambulatory dressing was twenty, and the results that had followed this treatment in these cases had been very satisfactory. After describing at some length his method of applying the dressing, demonstrating the apparatus in position, and referring to cases in which he had used it, Dr. Pilcher drew the following conclusions: 1. That the main object in the treatment was to enable the patient in a few days to get up and walk about on the fractured leg. 2. That union was accelerated in many cases; comfort, appetite, digestion, and sleep were secured; swelling, muscular atrophy, pneumonia, and delirium tremens were prevented, and flexion and extension were maintained. 3. That in the application of the dressing the foot was kept at a right angle to the leg, and extension was maintained until the deformity was corrected and the legs were of even length. 4. That the material usually employed was plaster of Paris, in which wooden or metal strips might be included; there should be a very thick plaster sole, separated from the foot by a layer of cotton about five centimetres thick, the plaster having been carefully molded with the hand, so as to fit snugly against the upper end of the tibia and about the dorsum and ankle. 5. It was generally thought best not to apply the dressing until the second or third day after the accident. 6. The patient must remain under observation in order that any displacement, undue constriction, or other defect might be noted. 7. In fractures of the thigh a combination of plaster of Paris and glue was recommended by some, while others had used special splints. 8. The plaster might be made to include the pelvis. 9. The dressing might be applied to the leg, and then allowed to harden, after which the patient's hips were raised from the bed, extension having been made to correct displacement, and the remainder of the dressing applied. 10. An important feature of the dressing was its strong re-enforcement and close application at the upper and back part of the thigh, thus securing a firm bearing against the ischium and the perineum. 11. That the sooner the immobilization was effected the less would be the swelling. 12. That the method could be applied with great satisfaction, and that an exact fit must be secured.

Dr. A. T. CAROT said that in two cases the use of Dr. Pilcher's apparatus had been of benefit in his hands.

Dr. NICHOLAS SENN, Dr. DE FOREST WILLARD, Dr. CHRISTIAN FENGER, Dr. J. EWING MEARS, Dr. CHARLES B. NANCREDI, and Dr. GEORGE W. GAY did not agree to the methods of treatment suggested by Dr. Pilcher and Dr. Owens.

Dr. H. H. MUDD, of St. Louis, thought the apparatus might work very well in certain cases.

Dr. MOORE stated that he had had good results from the employment of this method of treatment in two cases.

#### The Treatment of Traumatic Lesions of the Kidney.

—Dr. W. W. KEEN, of Philadelphia, after reading a tabulated list of a hundred and sixty-three cases of renal traumatism published since 1878, stated that traumatic lesions had, as a rule, two advantages over the lesions of disease: 1. As they were generally unilateral, the other kidney was not injured. 2. The injured kidney was apt to be healthy or fairly so. Gunshot wounds, on the contrary, have two disadvantages. 1. The treatment of the kidney alone in many cases could not be solely considered. 2. If the renal substance was only moderately injured, no one would be willing to do primary nephrectomy. As to the treatment of gunshot wounds, they might be classed as follows: 1. Those involving only the renal substance. 2. Those involving the pelvis. 3. Those involving the vessels. 4. Those involving the ureter. The incision in most cases should be abdominal, either median or at the outer border of the rectus, and if the vessels were badly torn, so that not only was there a great deal of hemorrhage, but the integrity of the organ was threatened, nephrectomy should be performed. In treating the extravasated blood in case the kidney was not removed, if the bleeding was into the peritoneal cavity, the blood must be removed by abdominal section, but if it accumulated in the perinephritic tissues alone, it might be left undisturbed. In treating the kidney, if the wound was sufficiently large for it to prolapse, it should be sutured and replaced if its condition was suitable, and the same procedure might be carried out if the pelvis of the kidney was opened. A partial nephrectomy would be advisable if a portion of the kidney was so far severed that its future integrity was threatened. As the dangers of rupture of the kidney were primary and secondary, the treatment might be conveniently so divided. Usually it must be decided if a nephrectomy should be done within the first few days or even hours, but it might occasionally be postponed and become a secondary operation, while the lumbar route would be best. In a hundred and sixteen cases of rupture of the kidney which were reported, sixty-six patients had recovered. Secondary nephrectomy was nearly twice as fatal as primary.

**On Susceptibility and Immunity, with Special Reference to Surgical Cases.**—Dr. ROSWELL PARK, of Buffalo, in a paper on this subject, said that man seemed to be proof against numerous infections which were common to many of the domestic animals, such as, for instance, those of hog cholera, symptomatic anthrax, and chicken cholera, while he was, in common with them, susceptible to the infection of anthrax, glanders, tuberculosis, and actinomycosis. Then, too, men differed among themselves in susceptibility to the same disease. This, of course, was explained by the fact that, at the time of exposure, their bodies were not receptive or were more resistant. Immunity might also be local or constitutional, and congenital or acquired, and acquired immunity might be natural or artificial. Immunity was, in some sense, a racial characteristic, as, for example, in the

case of the Japanese, who, it was said, never had scarlet fever, but were more susceptible to beriberi than Europeans were, while the negroes escaped yellow fever and were less liable to malarial disease and dysentery than Europeans were. The conclusions of surgical importance which might be legitimately reached from the study of the conditions dealt with were essentially these: That the surgeon in emergency cases had to do the best he could, not merely with the means at hand, but with the issues at hand, and here, so long as he could control what might happen outside of the body, he had done his full moral and legal duty. On the other hand, in any case where there was time, it was the surgeon's bounden duty, bearing in mind a summary of the conditions which notoriously conspired upon the one hand, to lower vulnerability, upon the other hand, to afford protection, to so alter the habits, the diet, the surroundings, and the preparation of his patient as to restore his tissues and vital fluids, so far as possible, to their normal condition before he interfered with their functions by an operation. For years Dr. Park had contended that, since the inauguration of the so-called antiseptic era, and in our enthusiasm for combating infection from without, we had lost sight of a most important truth which we could not afford to disregard, namely, that in our enthusiasm for combating infection from without, we had almost neglected the measures, first, for the recognition and, second, for the successful prevention of infection from within.

**The Effect of Anæsthesia upon the Temperature.**—This was the subject of a paper by Dr. DUDLEY P. ALLEN, of Cleveland, who dwelt very fully on the results obtained in a large number of experiments, principally upon dogs, and gave the details of each observation.

Dr. Gay, Dr. Park, Dr. Harte, Dr. Fenger, Dr. Willard, Dr. Abbe, Dr. McGraw, and Dr. Nancredi heartily indorsed Dr. Allen's methods and views.

Dr. PARK, who represented the committee on the nomenclature of tumors, presented a printed report showing the method suggested by the committee of classifying tumors.

Dr. GASTON demonstrated upon the cadaver an improved method of exploring the thoracic cavity.

Dr. S. H. WEEKS presented his report as a delegate to the British Medical Association in 1895.

**Retention from Bending, and Valve Formation (Oblique Insertion) in the Biliary Tract.**—Dr. CHRISTIAN FENGER exhibited morbid specimens and diagrams which demonstrated his method of treating this affection.

**An Unusually Large Periosteal Sarcoma of the Thigh Successfully treated by Extirpation.**—This paper was read by Dr. JOSEPH RANSOHOFF, of Cincinnati.

#### SOCIETY OF ALUMNI OF BELLEVUE HOSPITAL.

*Meeting of March 4, 1896.*

The President, Dr. PARKER SYMS, in the Chair.

**Pseudo-Leucocythæmia.**—Dr. A. BROTHERS presented a case of this kind, with the following history: Mrs. K., forty-six years of age, married twice. With the first marriage she had had eight children and two miscarriages. With the second marriage, fourteen years ago, she had had one child, now twelve years old, and two miscarriages. She had passed the menopause six years ago. She had always been a strong, healthy woman, and had

suffered so much from adiposity that she had constantly prayed to grow thinner. Her prayer had been answered. She had never had malarial or any severe illness, although she had spent her life in poverty, hard work, and miserable surroundings. Her present illness dated back a year, when she had begun to lose appetite, feel tired, and grow weak. Since that time she had lost fully fifty pounds, and had felt hardly strong enough to drag herself about; but, with the persistency of ignorance and superstition, she had preferred the squalor of her tenement basement to the comforts of a hospital. About eight months ago she had begun to suffer from pains in the left lumbar region, and had noticed a hard swelling which had since then increased so as to be not only felt but seen. Her complexion had gradually assumed a deathly pallor, and she had suffered from sleeplessness, listlessness, cardiac palpitation, dyspnoea on exertion, and occasional vertigo. Her mind had been perfectly clear, and she had had no unusual headaches. She had had attacks of vomiting from time to time, and had suffered intensely from constipation. Although not dropsical on rising, her feet had swollen during the course of the day. Examination had revealed a frail, thin-built woman, with intense anæmia of the skin and of the buccal and conjunctival mucous membranes. The lungs had been normal. The heart had been the seat of a loud mitral systolic murmur. The kidneys had been apparently normal. The abdomen had been disproportionately large, and, in the left half, had shown the margin of a tumor which had extended from the ribs to the ilium, and had measured ten inches and a half in the vertical diameter. It had proved on palpation to be the enlarged spleen. To the right, the liver could be felt enlarged to the extent that its vertical measurement was seven inches. The lymphatic glands of the cervical and inguinal regions had been moderately enlarged. The blood had shown under the microscope a decided diminution in the entire number of red blood-corpuscles, which had been of varying sizes and contour. White blood-cells had been present in about the normal ratio—about one leucocyte to three hundred red globules. The microscopic examination had been first made by Dr. A. Jacobi, and had been confirmed by the speaker. The diagnosis, therefore, the speaker said, was pseudo-leucocythæmia of the splenic variety, in contradistinction to the lymphatic. Bone marrow had been tried, on the suggestion of Dr. Jacobi, but the patient had given it up after a short trial. For several months she had been treated with arsenic, pushed to the point of tolerance, and although she was far from well, she felt better, and it seemed that the splenic tumor had grown smaller.

Dr. GEORGE W. CRARY said that within a year he had seen a case of splenic leucocytosis without any other symptoms. The enlargement of the spleen had been detected accidentally. Examination of the blood had shown a very marked diminution in the number of red blood-cells. The man had been thin, but muscular, and the condition had not given rise to any trouble.

Dr. COAKLEY asked if there had been any attempt to distinguish between the kinds of blood corpuscles present—whether the ratio of multinuclear and uninuclear cells was normal.

Dr. BROTHERS replied that no such distinction had been made, but the white corpuscles had presented the usual appearance of these corpuscles, and there had been about one white corpuscle to three hundred red corpuscles. He had tried giving the bone marrow

smear on crackers or bread, but the patient had appeared to grow worse, and her appetite had almost completely failed, so that it had become necessary to abandon this treatment.

Dr. C. C. BARROWS said that he had had a good many patients on bone marrow. When they had complained of the fresh marrow he had changed to a dried preparation. The progress of these cases had been apparently just as good as upon the fresh preparation, although since then authorities had generally agreed that the dried preparations were inert.

**Removal per Vaginam of an Ovarian Cyst complicating Pregnancy.**—Dr. C. C. BARROWS said that he desired to report the case as an illustration of the advantages of the vaginal method over the ordinary celiotomy. Mrs. T. C., an Italian, twenty-eight years of age, had been admitted to Bellevue Hospital on January 15, 1896. Menstruation had begun at the age of fifteen years, and for several years had been profuse. One week before admission she had missed her period. For a year past she had had pain about the pelvis with a feeling of weight, pain, and a bearing-down sensation in the region of the rectum. She had had five children and four miscarriages. She had dated her present trouble from the birth of the last child, one year ago. She had suffered almost constant pain since then, and had come to the hospital for the relief of this distress. On January 27th it had been noted that she presented the signs and symptoms of pregnancy. Physical examination had also revealed an ovarian cyst of about the size of a small orange, behind the uterus and apparently adherent in this location. Posterior colpotomy had been done on that day, the contents of the tumor evacuated, and the sac freed from its adhesions and removed, together with the left Fallopian tube, which had been adherent to it. The pedicle had been tied with silk, and the incision into the peritoneum and vaginal vault closed with catgut. The operation had occupied twenty minutes. The patient had made an uneventful recovery, and had been discharged two weeks after the operation, well. She had since missed her second period, and her pregnancy was progressing satisfactorily. This case was reported because it illustrated the advantages of vaginal over ordinary celiotomy. This woman's pregnancy had not been interfered with, and her abdominal wall was intact for her approaching labor.

Dr. BROTHERS said that he had been present at the operation, and had been greatly impressed with the facility with which it had been done. It was also very remarkable that the pregnancy should have continued in spite of the operation. He recalled a case in which a woman had come for a cervix operation. The operation had been done by a most eminent gynecologist without his knowing that she was pregnant, and without interrupting the pregnancy. This was important as showing that certain operations could be performed on the gravid uterus without disturbing the course of pregnancy.

Dr. WIGGIN said he wished to confirm the statement of Dr. Barrows about the ease with which small ovarian cysts of this kind could be removed by the vagina. Certainly there was much less danger of intestinal adhesions and infection of the peritoneal cavity, and the convalescence was more rapid and more satisfactory.

Dr. BARROWS said that trachelorrhaphy was an operation which had been advised and pursued by many surgeons in cases of badly lacerated cervixes for women who had habitually aborted, the cervix being sewed up during

pregnancy for the very purpose of preventing abortion by restoring the support of the uterus and relieving congestion.

(To be continued.)

## New Inventions, etc.

### A NEW SELF-CLAMPING NEEDLE HOLDER.

By WILLIAM L. BRADY, M. D.

THE following cut represents a needle holder which I recently devised for general surgical purposes. It is composed of two pieces of highly tempered steel of different sizes. The larger piece of steel is so bent upon itself as to rebound when the two parts of the curve are made to approximate one another. It is this part of the instrument which gives it its self-clamping power. This power is obtained by having the tip end of this curved piece of steel constantly press under the posterior extremity of the smaller piece. The smaller piece of steel is locked to the larger piece by a pivot working in a depression on this larger piece of steel. There is a groove leading to this depression which aids in the separation of the two parts of the instrument for purposes of cleaning, etc. That part of the needle holder which is grasped by the hand is corrugated so as to give the operator perfect control of the instrument.

The jaws are grooved for different-sized needles.

The advantages alleged for the instrument are: 1. The constant pressure which is always exerted on the needle the moment the spring is released. 2. The ease

with which needles are released from its grasp. In many of the needle holders now in use, an enormous amount of pressure is brought to bear upon the needle in order to release the same. 3. The simplicity of the instrument both in detail and working.

The needle holder is made up in different sizes to suit the various kinds of surgical work. It is used and endorsed by some of the very best surgeons of the city.

The principle of this instrument is applied to a haemostatic forceps which I also very recently invented.

The instruments are manufactured by George Tiemann & Co., of New York.

## Miscellany.

**The Use of Antistreptococcus Serum in a Case of Acute Hæmorrhagic Septicæmia.**—In the *British Medical Journal* for July 4th Mr. Charles A. Ballance and Mr. Francis C. Abbott, of St. Thomas's Hospital, London, mention, in the interest of those who make post-mortem examinations or are otherwise exposed to septic

infection, the case of a physician, thirty years old, who pricked his thumb in making a post-mortem examination in a case of suppurative peritonitis at 1.15 p. m. on Monday, June 8th. At 7 p. m. the thumb began to throb, and during the evening this throbbing increased to burning pain, and between 9 and 10 the red lines of lymph-duct inflammation had extended as far as the axilla, and the glands in that region were enlarged. At 4 a. m. on June 9th pain and tension of the pad of the thumb were so great that nitrous-oxide gas was given and an incision made. Previous to this vomiting had occurred, and there had been several shivering fits. The temperature at 7.30 a. m. was 103° F.

At 9.30 a. m. he was seen by one of the authors. The whole body was covered with a scarlet septic erythema; the face was partly and the eyes were suffused. The patient complained of severe shooting pains up the arm, and in the intervals of pain was listless and drowsy; the temperature was high and the pulse rapid and soft. It was arranged at once to take him as soon as possible to St. Thomas's Hospital, where he was admitted about 3 p. m.

The condition gradually got worse, and on the evening of the following day (June 10th) the temperature was 104.7°, and the pulse 150, soft, feeble, irregular at times, and running. The rash was very brilliant, and hæmorrhagic in places. All day drowsiness had been a marked feature, and the respiration was more rapid than normal, and occasionally jerky. Nourishment was taken with difficulty. There was soreness of the throat, which was of a brilliant red color. During the day vomiting occurred several times, and also slight bleeding from the nose. Coughing, too, was troublesome, and he hawked up blood-stained mucus from the pharynx. There was no swelling of the thumb, and no discharge of pus from the incision, but there was great pain and tenderness along the forearm and arm, though without obvious swelling or œdema. The axillary glands were large and tender. The red lines were obscured by the rash, but the hard lymph cords could be felt. There was frontal headache and the mind was clouded. The tongue had gradually become coated and dry, and was passing into a typhoid condition. There was slight albuminuria.

At midnight (June 10–11th) 3.5 c. cm. of antistreptococcus serum (Burroughs and Wellcome) were injected. This was repeated every four hours. Six hours after the first injection (6 a. m., June 11th) certain indications of improvement were manifest:

1. The mind was clear, and the headache had disappeared.
2. The respiration was regular and less rapid.
3. The pulse was slower.
4. The tongue was moist along the edges.

On June 11th the temperature was continuously 104° F. Cold sponging, which was done several times, had no real effect. The tongue continued to clean, but a smart attack of epistaxis occurred. The rash was still as bright, and the blotchy subcutaneous hæmorrhages were more evident. Toward evening, after the epistaxis occurred, the pulse became much more rapid and weak, and gave rise to much anxiety. Strychnine and digitalis were ordered every four hours.

During the night the temperature dropped, but much pain and some swelling were noticed in the ball of the thumb, and there was tenderness above the wrist on the radial side, with slight œdema. Notwithstanding the bad night the general condition was better.

On June 12th the skin was moist, and the tongue

\* Presented before the Society of Alumni of Bellevue Hospital, April 1, 1896.

was steadily cleaning from the edge, leaving a marked pink, moist surface, such as is seen on the throat in diphtheria when the membrane clears under the use of antitoxine. Chloroform was given, and an incision into the thenar eminence, opening the sheath of the tendon, was made; also one over the first phalanx of the thumb. The parts, though swollen and tense, contained no visible pus. At midday the dose of antitoxine was doubled, 7 c. cm. being injected every four hours.

No further incisions were necessary, the swelling and œdema above the wrist gradually disappeared, and the incisions all began to heal without any visible discharge of pus. The rash did not disappear entirely until June 16th.

The use of the antitoxic serum appears to the authors to have produced the following effects:

1. The mind became clear notwithstanding the high fever.
2. The frontal headache ceased.
3. The tongue began to clean and become moist from the edge until it was clean, moist, and of a peculiar pink color all over.
4. The pulse became slower and of better quality.
5. The respiration was slower and never jerky afterward.
6. The skin, which was dry and burning, became moist, and sweating occurred.
7. The wounds healed without suppuration; and the threatened inflammation of the great synovial sac under the anterior annular ligament subsided.

Every care was taken to aseptize the syringe used for the injection, to cleanse the skin at the site of injection, and to maintain the sterility of the serum by keeping it in ice, and using other obvious precautions. The injections were given into the loin and abdominal wall. Notwithstanding the large number of injections (twenty-eight in all, eight of  $3\frac{1}{2}$  c. cm., and twenty of 7 c. cm.), no local reaction occurred at all except a fleeting urticaria limited to the site of injection, which was noticed once or twice, and did not produce any inconvenience.

The recovery, the authors add, would seem to encourage the employment of the antistreptococcus serum in many other serious surgical conditions. Among many others, the following occur to them: Fracture of the skull with risk of suppurative meningitis, acute necrosis, acute septicæmia or pyæmia from any cause, rapidly spreading gangrene or cellulitis, erysipelas, general suppurative peritonitis, and the septic complications of middle-ear disease.

With regard to the dose, they would be inclined to begin by injecting a large one—say 20 c. cm.—and then to give a smaller dose—say 7 c. cm. every four hours. After most of the injections given in the case related, the temperature temporarily dropped, but soon rose again, and they fancy that it is of great importance to give the injections frequently.

**Veratrum Viride and Gelsemium in the Treatment of Traumatic Tetanus.**—In the *Medical News* for July 18th Dr. Fordyce Grinnell, of Pasadena, Cal., relates the case of a boy, six years old, who, while barefoot, cut the ball of his left foot on a piece of glass. The wound apparently healed. Some nine days after (on April 14th), he complained of stiff jaws and difficulty in swallowing. These symptoms increased until, on the night of the 16th, tetanic spasms began to manifest themselves. The cicatrix of the wound was cleaned and scraped. It seemed somewhat tender on pressure, but no foreign

body was discovered. The site was scarified, however, and turpentine and oil were applied, and four-grain doses of ammonium bromide were given every two hours.

As no perceptible improvement was noted, on the 17th Norwood's tincture of veratrum viride was given, at first a drop every hour, then two drops every hour. As this did not seem to prevent the return of the spasms from time to time, fluid extract of gelsemium was given, at first in drop doses every hour, in conjunction with the veratrum, then in two-drop doses, and finally in three-drop doses. The dose of veratrum was also increased on the 20th to three drops every hour, so that the child was taking three drops each of the veratrum viride and the gelsemium every hour, and it seemed to require this amount to control the spasms. These doses were continued for forty-eight hours. Only once during this time did they produce active vomiting or sufficient nausea to require an opiate to control it. When this relaxed condition was obtained, the drops were decreased to two of each on the 22d, and on the 25th to one of each, which was continued until the 27th, when the interval was lengthened to two hours, and gradually thereafter the doses were discontinued.

The ammonium bromide was given in three- to four-grain doses every two hours during this entire period. The use of the remedies in diminished doses was continued to the 30th of April, when the boy could open his mouth without difficulty, had a good appetite, and was playful, but more boisterous in his manner than usual, or, as his mother said, "more nervous."

The instructions had been to decrease the amount and frequency of dose when distinct signs of nausea appeared or the signs of convulsions abated.

The author was led to try veratrum on account of its value in puerperal and other convulsions, and gelsemium by its action in causing relaxation of the muscles of the jaw.

#### The Action of Carbonic Acid on the Sexual Organs.—

In the *Deutsche Medicinal-Zeitung* for June 29th there is a paper that was read by Dr. Schuster, of Bad Nauheim, before the Seventeenth Congress of Balneologists, held in Berlin. Although, remarked Schuster, it had long been known that carbonic acid had an effect on the sexual organs, that knowledge had hardly been turned to account in practice. In his work *Ueber die Vielseitigkeit der Kurmittel Nauheims und seiner Indikationen*, he had made brief mention of the fact that those of the Nauheim waters that were rich in carbonic acid had such an influence upon men under certain circumstances that easily impressible patients had erections even in the bath, and sexual desire was materially increased in many patients by the course.

In a bath of highly carbonated water, after a few minutes, as was well known, there was a sense of increased warmth, often of slight burning and prickling, especially on the inner surface of the thigh, on the perinæum, and on the scrotum or the labia, which was accompanied by reddening of the skin of those parts. Therefore carbonic acid had an irritant action on the nerves and blood-vessels of the skin. It was probable that this peripheral irritation was conducted centripetally and gave rise to a change in the nervous and vascular systems, together with a change in metabolism. It would not be strange if an influence upon the sexual apparatus also was exerted if we considered the fact that, in the male as well as in the female, the sexual nerves went very near the surface. It was well known that peripheral irritations in the neighborhood of the genitals

evoked or heightened sexual desire, and in the male sex were the direct cause of erections. Fürbringer had spoken of irritation of the perineum as particularly prone to give rise to erections, manifestly in some measure because of the part played by branches of the nervi erigentes in the innervation of the rectum.

The author then quoted several writers, some of whom had observed that the action of the baths was so pronounced as to cause nocturnal emissions in old men who had for years been free from them. One of these writers, Küster, had in the majority of instances found that in women the effect on sexual desire was only trivial.

In regard to the use of these baths in cases of impotence, it was unnecessary to say that it was ineffectual in those that depended on congenital malformations or defects, or were incidental to such diseases as diabetes, nephritis, cerebral syphilis, tabes, or other spinal affections, or were due to atrophy of the testicles, to stricture, or the like. Moreover, it could have no effect on impotentia generandi, but only on impotentia coeundi; in short, it was only in cases of sexual neurasthenia, nervous impotence, that it could be effectual, and in but certain forms of this, such as those which, as Eulenburg had expressed it, depended on diminished calls upon the spinal centres and their consequent functional impairment or on disturbances of the peripheral reflex paths. It might also be of service in impotence due to impairment of the cerebral centre. It was directly contraindicated in spermatorrhœa and in cases of premature ejaculation. The author thought the treatment had a particularly favorable field in so-called senile impotence that had come on prematurely.

In regard to women, the author cited Kisch and Loimann's observations of the good effect of carbonic-acid baths in cases of dyspareunia and anaphrodisia and in promoting menstruation. Loimann, in opposition to an author previously cited, had expressed the opinion that the aphrodisiac action of carbonic acid on women was even greater than on men. Schuster then mentioned briefly certain other diseases of women in which the carbonic-acid treatment had been observed to have a good effect or was likely to, such as uterine and ovarian neuralgia and consequent hysteria or neurasthenia, dysmenorrhœa not dependent on mechanical obstruction, amenorrhœa, and chronic metritis.

**Senecio as an Emmenagogue.**—The *Gazette hebdomadaire de médecine et de chirurgie* for July 2d contains a report of a recent meeting of the Société de thérapeutique at which M. Heim and M. Dalché related the results of their experiments with two varieties of senecio, namely, *Senecio vulgaris* and *Senecio jacobœa*. They made use of extracts in which they found two alkaloids, senecine and senecionine, and a crude resin. The effects of the extract on the sensory nerves were little known; on the motor nerves, a strong dose provoked modifications which were analogous to those produced by curare. The number of heart-beats was diminished by the use of weak doses; a strong dose caused the arrest of the organ in systole.

Their experiments made on dogs and rabbits showed that the extract of senecio was well tolerated, even in large doses. With regard to its emmenagogue action, the authors stated that they had tried the drug in fifteen cases and had found that it ameliorated dysmenorrhœa and amenorrhœa, that is, those forms which could not be attributed to inflammation of the uterus or of its annexa. In cases where these organs were involved

senecio should not be employed, as it aggravated the patient's condition in a singular manner.

M. Bolognesi stated that he had made a study of the action of senecio in twenty cases, and that the results of his observations led him to think that the drug was a good emmenagogue in amenorrhœa, even in cases of long standing. In certain cases it provoked menstruation; in others it regulated this function. It had no influence on pain, and it had never aggravated the causal disease of amenorrhœa. In strong doses it seemed to provoke a sort of utero-tubo-ovarian erection.

M. Bardet said that he had seen cases in which the results had left no doubt as to the peculiar action of senecio on the uterus. In one case it had provoked nausea and uterine contractions which manifested themselves by sensations similar to those produced by the gravid uterus. In another case the drug had caused miscarriage.

M. Blondel thought that the latter case reported by M. Bardet proved that *Senecio jacobœa* had a true congestive action on the utero-ovarian apparatus; its physiological action, however, he said, seemed to remain very obscure. He thought that M. Heim's and M. Dalché's observations in regard to this were extremely vague, and conflicted essentially with what had been observed by M. Bardet and M. Bolognesi. In practice, he said, an emmenagogue should not be employed until its mode of action had been ascertained, in order that its indications and contraindications might be clearly established. Amenorrhœa, in reality, was not a disease, but a symptom, and it was to its physiological causes that the treatment should be directed if we desired to combat it, by changing our modes of procedure. In addition to the amenorrhœas commonly met with, those which depended upon anæmia, for example, there were forms which were connected with a structural defect of the uterus, ante-flexion, retroflexion, accidental atresia of the neck of the uterus, spasm of the internal orifice, etc., and it was indispensable to establish all this before selecting an emmenagogue. In some young chlorotic girls iron acted marvelously; in others, who were lymphatic or nervous, douches were excellent. After serious infectious diseases, such as typhoid fever, and after a physical or mental derangement which influenced menstruation, the greatest advantage was to be derived from exercise in the open air, such as walking or even riding a bicycle.

With regard to the so-called functional amenorrhœas, said M. Blondel, which depended upon the condition of the uterus itself, it was evident that the treatment of deviations was indicated when they were the cause. With regard to drugs which caused congestion of the utero-ovarian apparatus, whether they acted on the smooth fibre, as strychnine and salicylic acid did; whether they provoked congestion in the circulation of the true pelvis by irritation of the mucous membrane or by obstruction of the hepatic circulation; whether their use was directed to the ganglionic plexus by the intermediary of the central nervous system, the advantages were not seen, and all the dangers were not comprehended. We should not forget, said M. Blondel, that in the majority of cases the cause of amenorrhœa was pregnancy, and the difficulties which surrounded the diagnosis of this condition during the first months were well known.

M. Blondel thought that, on the whole, the treatment should be indirect; the medicaments which acted directly by provoking uterine hemorrhages were frequently uncertain and sometimes dangerous, and when they did exert any action it was only transitory. Here, as in many

other cases, it was not the symptom which must be treated, but the cause. If any medicament was to be resorted to, potassium iodide was preferable, and it should be administered in daily amounts of from a grain and a half to three grains. It was especially adapted for the treatment of arthritic amenorrhœa, that was to say, to the majority of cases of amenorrhœa without lesions, which were those generally met with in private practice.

**Infantile Diarrhœas and their Treatment.**—In an article on this subject in the *Presse médicale* for July 1st, M. A. F. Plicque deals with the four principal forms of infantile diarrhœa, which, according to Lesage, are as follows: 1. Simple diarrhœa. 2. Bilious diarrhœa. 3. Green bacillary diarrhœa. 4. Cholera infantum.

Simple diarrhœa, he says, is often caused by cold and poor milk. In this form the stools are sometimes of a fatty consistence, yellow in color, and often putrid. This diarrhœa, which seems to be due to the bacillus coli, may be contagious. Even in the less severe forms, especially in summer, sudden complications, such as cholera infantum, typhoid symptoms, and meningitis, may occur, and, during the winter, broncho-pneumonia. It should therefore, be very energetically treated.

The cause of this affection may be, in natural feeding, the bad quality of the mother's milk or too frequent nursing. Lesage, says M. Plicque, has shown the frequency of gastro-enteritis in infants who are nursed by women who suffer from intestinal troubles. In cases of artificial feeding it may be due to improper sterilization and contaminated milk.

With regard to the treatment, M. Plicque considers it necessary to begin always with a slight purgative, which may in itself be sufficient to arrest the diarrhœa. If this fails, enemata of starch water with from half a drop to a drop of laudanum may be administered, and repeated two or three times a day if necessary. Internally, bismuth or astringents may be used. The following formula is prescribed by Barthès and Sanné, and is, according to the author, an excellent remedy:

Peppermint water.....	900 grains
Syrup of rhatany.....	300 "
Tincture of catechu.....	75 "
Gum arabic.....	135 "
Extract of logwood.....	30 "

A teaspoonful of this mixture is to be given every hour. If the diarrhœa is rebellious, it is always necessary to use opium.

Bilious diarrhœa occurs during the first year of life, and it is generally coincident with a slight icterus; it is observed in older children after slight attacks of indigestion, and in cachectic children who suffer from tuberculosis of the liver. The green color of the stools may resemble that seen in green diarrhœa, but the symptoms are not so intense. In doubtful cases the addition of a drop of nitric acid to the stains on the diaper gives the characteristic tints of violet and rose. This diagnosis is important, for the treatment consists, above all, in the employment of alkalies. Lesage recommends giving sodium bicarbonate in capsules containing from four to eight grains, which are to be administered in milk an hour or two before eating. The entire amount given during twenty-four hours should not exceed fifteen grains for each kilogramme (a little over two pounds and a fifth) of the child's weight. In any case not more than seventy-five grains should be given. The bilious diarrhœa which is connected with tuberculosis nearly always resists all treatment.

The progress of green bacillary diarrhœa, says the author, may be acute. It resembles, with the exception of the vomiting, infantile cholera, and fatal results may follow in a day or two. Even in the less intense forms pulmonary and meningeal complications are not rare. It may also become chronic and cause death slowly by atrespia. The various forms, says M. Plicque, seem to be associated in varying degrees with the virulence of the bacillus coli. The peculiar green color seems to be due only to a chromogenic transformation of the bacillus coli. The general hygiene and treatment is somewhat like that used in simple diarrhœa. Besides this, however, lactic acid must be employed, as, according to Hayem and Lesage, it appears to have peculiar antiseptic properties. M. Plicque recommends the following formula:

Lactic acid.....	30 grains;
Mucilage of gum arabic.....	3 ounces.

A teaspoonful of this is to be given at a time. M. Descroizilles recommends for such cases the association of a solution of hydrochloric acid and laudanum in the proportion of from one to two drops of laudanum in sweetened water to from fifteen to thirty grains of the solution. He attributes antiseptic properties to the hydrochloric acid, although they are not so energetic as those of lactic acid.

Cholera infantum, continues M. Plicque, often sets in during the course of the preceding forms of diarrhœa. It is accompanied by repeated vomiting and an intense and profuse diarrhœa, which is nearly always watery in character, but the dejecta do not, as in Asiatic cholera, contain ricelike grains. Occasionally greenish stools are seen. The abdominal wall, which is weakened and flabby, is as if glued to the spine.

Algidity with cyanosis and coldness of the extremities very soon sets in; this peripheral algidity does not always prevent a certain elevation of the rectal temperature. Collapse with a complete inertia occurs very rapidly, too, and it is interrupted by slight tremblings and energetic respiratory movements, which are like the tugging of croup during attacks of dyspœa. Even in the relatively benign forms, after the period of algidity, complications, such as abscesses, gangrene, hæmorrhage, venous thrombosis, etc., are observed during convalescence.

With regard to the treatment, says the author, alimentation must be assured if possible, in spite of the vomiting. Weak chicken bouillon is often better tolerated than milk. When the latter is given, from four to five drops of brandy or rum should be added to every teaspoonful of the milk. As a rule, the child is not able to nurse, and in this case the mother's milk should be given by the teaspoonful.

The treatment consists especially in the use of lactic acid combined with a solution of hydrochloric acid and laudanum. To combat collapse, stimulants should be employed internally and externally.

**Venesection in Opium Poisoning.**—The June number of the *Indian Medical Gazette* contains an article on this subject by Surgeon-Captain D. G. Marshall, of Umballa, in which he states that the value of this mode of treatment is, judging from the slight reference to it in any of the standard works, apparently little known, although it is so efficacious in apparently hopeless cases that it appears worthy of more general application.

It is referred to in Neale's *Digest*, one case being quoted as recorded by Griffin, and Dr. Ogle, in the *Lancet* of May 9, 1892, refers to Professor Reid's experiments on the results of bleeding in cases of poisoning.

This treatment, says the author, is not recommended as applicable to every case of opium poisoning, but it is beneficial in those cases where death is impending, owing to failure of respiratory action due to distention of the right side of the heart, with backward pressure. On the same line of reasoning it has been found useful in chloroform poisoning.

The following case, which came under his care in England, shows, he says, that the method of treatment has practical value:

A woman who had swallowed two ounces of laudanum with suicidal intent was brought to the hospital in a comatose condition. The stomach was thoroughly washed out and hypodermic injections of atropine were administered, but, in spite of these measures, the patient rapidly grew worse; the breathing slowed down to four respirations a minute, and finally stopped altogether. There was a faint pulse at the wrist—and the heart could be felt working in a labored fashion, and the right side was evidently distended.

Artificial respiration was maintained for about five minutes, but with no results, for the radial pulse was imperceptible and there was no sign of respiration; the heart, however, was still acting.

Having heard, says Mr. Marshall, of the beneficial result of bloodletting in opium poisoning, he opened a vein in the left arm, and allowed twenty ounces of blood to escape; he then continued the artificial respiration. In a few minutes natural breathing began again, and in half an hour the woman was sufficiently recovered to be walked about. She left the hospital the next day.

**The Remuneration of Expert Witnesses.**—"A decision of importance to all persons who are liable to be called upon to go on the witness stand as experts," says the *Journal of the American Medical Association*, "has been rendered by the supreme judicial court of Massachusetts in the case of *Barrus v. Phaneuf*, May 21, 1896. The principles which it discusses and lays down apply to medical experts, with full force, although this action was brought by a civil engineer. He had been engaged by the defendant to go into court at a future day and testify for him as an expert in regard to a matter which he had examined as such. This engagement was made about six weeks before the trial. He talked over the matter, and went into court and testified, and during the progress of the trial advised the defendant's attorney in regard to the questions to be asked of himself and of the other witnesses, though he was not asked any questions which called for his opinion as an expert. To further complicate matters, he was, at some time after the agreement was made, regularly summoned by the defendant as a witness, and was paid the statutory fees, and made no objection thereto, and made no claim for extra compensation. Was he entitled to recover any extra compensation as an expert? The defendant contended that he was not, and that if there was an express promise to pay him extra, it was without consideration, and that the witness did no more than he was legally required to do under his subpoena. That a court would be without power to require the attendance of a professional or skilled witness, upon a summons duly served, and with payment of the statutory fees, although he was unacquainted with the facts, and could testify only to opinions, the court declares it would be slow to admit; but such power would hardly be exercised unless, in the opinion of the court, it was necessary for the purposes of justice; and the one summoned would perform all that the court could require of him if he should hold

himself in readiness to be called upon to testify to such opinions as he might have when his turn should come. In this case, however, the court holds that the evidence showed a sufficient consideration to support a promise to pay a reasonable compensation, in addition to the statutory fees, and that the jury was warranted in finding a promise to that effect, or a mutual understanding that the expert was to be so paid. If such promise was made, or such understanding existed, it further holds that the expert's right to recover would not be taken away or lost by his omission to claim or demand extra compensation, or to notify the defendant that he should make such claim, or by his acceptance of the statutory fee without objection, or by the omission of the defendant at the trial to put any question to him as an expert witness, and the consequent omission on his part to testify as an expert. What would have been his right without such promise or understanding, the court studiously avoids stating except as above, though at the same time shows the trend of authorities would be against allowing any extra compensation."

**The Employment of Large Doses of Sodium Bicarbonate.**—At a recent meeting of the *Société nationale de médecine de Lyon*, a report of which appears in the *Lyon médical* for June 28th, M. Tournier related the case of a woman who suffered from an excess of hydrochloric acid in the gastric juice. She had been treated with instillations of silver nitrate, and nutritive enemata, but without beneficial results. A course of sodium bicarbonate was then prescribed and begun with amounts of from 180 to 225 grains a day. No relief having been obtained, the quantity was increased to 375 grains, but this amount also proved insufficient, and no real relief was felt until she reached the amount of 750 grains a day. Even this was increased, and without M. Tournier's knowledge the patient took, during a period of a month, from two ounces to two ounces and a half a day in doses of forty-five grains every fifteen minutes, in milk. During this time, said M. Tournier, there had been no disturbance of any kind and no anæmia, and her weight had increased three kilogrammes. The urine was abundant and presented a feeble alkaline reaction. The intestinal functions were normal.

M. Lépine thought that, in order to tolerate such large doses of sodium bicarbonate, there must be a special receptivity, a pathological condition with exaggerated acidity which should neutralize a part of the sodium. Large doses were incompatible with a normal condition, and it would be dangerous to give them to a healthy person.

**The Technics of Intubation.**—The *Gazette hebdomadaire de médecine et de chirurgie* for June 28th contains an abstract of an article which appeared in the *Münchener medizinische Wochenschrift* for 1896, No. 18. According to the author, Dr. Trumpp, says the writer, extraction of the tube may be easily effected without the aid of an extractor, in the following manner: The physician places himself directly in front of the child, surrounds the child's neck with his hands by placing his thumbs below the cricoid cartilage and his fingers on the nape of the neck, and then exercises with his thumbs a sudden and rather energetic pressure above and behind. This movement provokes an attack of coughing and reflex strangling which drives the tube into or even out of the mouth. This procedure has been employed daily at Escherich's clinic with successful results, and has never provoked the least complication.

### SOME APPARATUS FOR THE TREATMENT OF POTT'S DISEASE.\*

By JOHN C. SCHAPPS, M.D.,  
CHIEF OF DEPARTMENT OF ORTHOPEDIC SURGERY,  
ST. MARY'S HOSPITAL, BROOKLYN, N. Y.

THE controlling principle in the treatment of Pott's disease is rest, or relief from pressure and motion. Posture, fixation, traction, leverage are the means employed to secure it and to prevent deformity. The completeness of the rest must be proportionate to the activity of the disease. But, though Nature does not demand at the same time rest and work, the old bugbear, fear of confinement (or of lack of exercise), which has been responsible for a vast amount of deformity, suffering, and death, itself dies hard. It is well that those of us who, in the treatment of Pott's disease, have made use of prolonged recumbency upon a surface fitted to the patient, and with both pressure and traction, should testify, on all proper occasions, that it is beneficial and not harmful—not even uncomfortable. On a wheel-cot recumbent patients can enjoy the air and sunlight and have their world greatly enlarged while submitting to the best possible conditions of repair (Fig. 1).

FIG. 1.—Four-foot cot.

This cot (Fig. 2) is the result of successive modifications of the wooden one presented at the meeting of this association held in New York in 1892, and of the folding iron cot shown in 1893. The changes were made with a view to simplicity and compactness. It consists of an iron stretcher, carrying a tightly laced canvas, and supported upon rubber-tired wheels in such a man-

ner as to permit any required inclination. Fig. 3 shows the construction of the working parts. It is provided

FIG. 2.—Four-foot cot.

at the head end with a pulley. In the canvas is a narrow oval opening for the purposes of defecation and urination. In a cot four feet long—a common size for children—it is six inches by two inches and a half, and its

FIG. 3.—Showing the construction of the working parts of a four-foot cot.

- I. Side view. A, upright three-eighth-inch brass pipe. B, side of stretcher, three-eighth inch iron pipe. C, corner casting. D, iron bushing, three-quarter-inch by three-eighth-inch, inner thread reamed off inside; lower, inner edge beveled at twenty degrees; upper edge rounded. E, beveled ring made from a similar bushing, screwed in, cut off, and fastened by a pin. F, split beveled collar of hard rubber. As D is screwed down the collar is closed on the upright, and the frame is held at any desired inclination.
- II. Horizontal section through *ab*. The references are the same. The wickets at each end of the cot are made of eighth-inch brass pipe. The vertical parts slide into the uprights and are secured at any level by a construction like the preceding. The top of the three-eighth-inch pipe is beveled to take the place of the ring E. A three-eighth-inch coupling three-eighth-inch by one-eighth-inch bushing and a hard-rubber beveled and split collar complete the fastening. The rest of the cot is put together by ordinary pipe fittings, and the axles are screwed into simple castings. The sizes of pipe are for a four-foot cot three-eighth-inch; for five-foot, half inch; and for six-foot, three-quarter-inch or inch.

\* Read at the annual meeting of the American Orthopedic Association, Buffalo, N. Y., May 21, 1896.

centre is located three fifths distant from the head of the canvas. It is closed by a flap underneath. In planning

cots for adults, I find that the opening must be made nearer the head, and it is then a safer rule to make each canvas according to the patient. There is also a line of loops on each side, near the upper end, through which

FIG. 1. Polyvinon

pass shoulder straps. The arrangement of pads and straps and the use of the cot have been much simplified.

To prepare a cot for a patient, he is placed upon it so that the anus is at the upper end of the opening, and marks are made on the canvas by means of which the situation of the diseased part of the spine can be determined. He is then removed. Pads from one to two inches thick of boiler felt are laid upon the canvas so as to make a surface conforming to the patient's back. In cervical cases it is particularly necessary that the hollow under the neck be filled. When there is a dorsal or lumbar kyphos a block of padding as broad as the back, long enough to extend from the neck to the buttocks, and having a small slit to receive the tip of the bony prominence, is used. The upper and lower edges of the pad are thinned by cutting to different lengths the layers of which it is composed, and the edges of the slit are trimmed a little. If there is a pronounced lumbar hollow an additional pad is put across under the large one. A folded sheet is placed over the pads from the head of the stretcher to just below the upper end of the opening. This must be wide enough to cover the pads and narrow enough not to cover the loops. A second sheet is placed from the lower edge of the first to the foot of the canvas. This will be more frequently changed. The patient is tied

buckled around the sides of the stretcher. A pillow is placed under the thighs and legs, which are secured by a piece of stout muslin pinned around them and the stretcher. Traction may be made by a head sling (Fig. 5) and weight attached to a cord passing over the pulley, or the head sling may be fastened from the two upper corners of the frame, after the method of

FIG. 6. The force of gravity, exerted as shown by the arrows, tends to separate the bodies at the site of disease.

Dr. Steele.\* The stretcher is sloped for counter traction, or straps from the pelvic belt to the foot of the stretcher may be used for the purpose.

The pressure straps constitute a most important feature. They are buckled around the sides of the stretcher and pass under the canvas at the diseased part of the spine. The amount of pressure can be thus accurately adjusted. The parts above and below by their weight not only cause backward leverage, but, as the spine is resting on the spinous processes and the centre of motion is behind the bodies, actual traction on the bodies is secured (Fig. 6). This is confirmed by the experiments of Dr. Lovett,† presented at the last meeting of this association, in which he shows that patients are longer when recumbent. A mark is made on the canvas at the level of the patient's head to indicate his position. It is necessary that this

should be always the same, in order that the diseased part be kept on the pressure straps. The degree of pressure that can be borne is determined by the appearance of the skin over the part. As a rule, I do not tighten the straps until after a week or more, when under the pressure of weight a shallow trough, which fits the back and affords good fixation, is formed. The patient is dressed in a garment without a back (Figs. 7 and 8).‡ In cervical cases it is better to pin it to the sheet on each side of the neck than to pass the collar behind. Once comfortably fitted to the canvas, the patient should be moved as seldom as possible. A slight turning between two persons, one taking the head and shoulders and the other

FIG. 5. Head slings. *a.* Sayre's. *b.* One made of a single piece of web and a buckle and two rings. A strap may be passed from ring to ring under the chin. *c.* Sling made of a piece of web and two rings. The light A is passed under the chin and the cross B under the occiput. Steele uses a four-tailed bandage. Two of the tails pass up in front of the ears, and two backward to cross under the occiput, as in *c.* (*Trans. of the Am. Orthop. Assoc.*, 1895.)

on. By feeling the lower side of the canvas it may be determined what changes are necessary in order that the entire back be supported. When this is accomplished, web straps are passed through the proper loops under the shoulders and buckled either crosswise over the chest or around the shoulders. The pelvis is secured by a curved canvas belt (Fig. 1) from which straps are

‡ *Ibid.*, and *American Medical Association Bulletin*, December 15, 1895.

the pelvis and legs, will give ample access to the spine. Alcohol and powder should be applied twice daily, and the skin watched for pressure marks. Such cases, even

The upright position is in all cases sooner or later adopted, and a clear conception of the condition of the spine and the possibilities and principles of mechanical support in this position are then essential. The weight of the parts above is by no means all that the diseased bone has to bear. There is also that of the parts which,

FIG. 7.—A garment without a back, for a recumbent patient.

FIG. 8.—Pattern.

though painless, should be handled with great care, and the relations of the diseased parts changed as little as possible. For adults, cots are mounted on two large wheels and two small ones which turn on ball bearings like casters (Fig. 9), and for those children who can

FIG. 10.—Four-foot cot.

though situated below, are suspended from above. The viscera of the abdomen make downward traction on the spine at a much higher level than their own. The upper extremities are, by means of muscles extending upward from the clavicles and scapulæ, suspended from the head and cervical vertebræ. The thorax, its contents, and the abdominal muscles attached to it are also, to some extent, suspended. The diseased spine is subject also to muscular action exerted between the parts above and those

below. By reason of the forward projection of the face, chest, and pelvis, much of this force is applied in a deforming manner, and at a great leverage. It is exposed, also, to constant jar and to strain from the voluntary muscular efforts concerned in equilibration and in the ordinary and necessary motions of either extremity. In addition, there is the great pressure from reflex muscular spasm or Nature's automatic splintage. And the energy required to hold the spine rigid and the lower limbs in a continuous state of elastic tension to break shock, besides producing spinal pressure, is exhausting, and lowers the local and general recuperative powers of the patient.

FIG. 9.—Six-foot cot.

not afford a wheel-cot I have the canvas stretched on a frame with short legs that can be easily lifted about (Fig. 10). To give it a slope, the supports at the foot are shorter than those at the head. The object of having the canvas suspended by its edges, in both cot and frame, is to prevent change in position of the diseased parts of the spine in raising the patient from and replacing him upon a bed.\*

Not only are the adverse conditions of the spine itself enormously increased, but the mechanical possibilities of treatment appear very inadequate. Apparatus can not be applied as are splints to a broken limb. We must act on the spine from a considerable distance. The object sought is to fix the diseased part of the spine, or keep it forward in its relation to the parts above

\* The canvases are made by Messrs. John Boyle & Co., 199 to 207 Fulton Street, New York. The cots, frame, or any other apparatus de-

scribed in this paper, will be furnished by the Orthopaedic Department of St. Mary's General Hospital, Brooklyn. Exact dimensions must be given.

and below, and to counteract the deforming forces mentioned. Those portions of the body surface that are capable of transmitting support are limited. Backward pressure can be exerted on the forehead, sometimes slightly on the chin, on the front of the chest, and on a small area around the anterior superior iliac spines. Vertical support or counter traction may be had from the crest of the ilium, the gluteal muscles, and the posterior surface of the sacrum, when, as is not the case in a child, these parts are sufficiently developed. From this as a base, upward pressure can be exerted on the front and back edges of the axilla, on the chin and back part of the head, and against the under side of a markedly projecting kyphos. It is not only futile, but a decided injury, to make pressure on other parts, and particularly to interfere with the respiratory movements of the chest and abdomen. For a yielding abdomen can not transmit the force applied, and it is possible that limiting normal respiratory motion we may divert its force to the weak place in the spine; and abdominal distention and movement tend to diminish instrumental pressure upon parts where most needed. According to Holden, the respiratory movements of a rib take place, principally, by rotation around an antero-posterior axis drawn between its ends. The greater the curvature the greater the respiratory capacity. In inspiration, most children will be observed to expand the lower chest laterally more than anteriorly. All can breathe in that way. This movement need not be interfered with for spinal support. Indeed, by directly backward pressure and avoiding lateral pressure, the normal curvature and lateral motion of the ribs are conserved. On the other hand, if this rib motion be restricted by deformity or apparatus, or by both, and by abdominal pressure what respiratory movement remains be obstructed, the interference is considerable; and in a patient with a tuberculous disease any interference with respiration is a most serious consideration. The evils of circumferential constriction of the trunk are familiar to every student of elementary physiology, and Pott's disease confers no immunity. The results to the abdominal and pelvic contents are graphically described by Dickinson in his paper on the corset.\* The pelvic organs of little girls (and most of our patients are children) are easily displaced. Protrusions at the inguinal ring have also been observed in patients wearing constricting apparatus. Such pressure contributes nothing to the support of the spine, and its evils are vastly greater than could possibly be attributed to recumbency. When the shape and area of surfaces available for spinal support, their lack of natural padding, their distance from the seat of disease, and the mobility of the intervening parts are considered, the impossibility of giving adequate mechanical protection in the upright position in any but the convalescent stage is apparent. This stage can

be hastened by systematic recumbency as described. The upright position should be assumed, under careful supervision and for slowly increased periods, and only in those cases in which a moderate amount of support is sufficient. All that is possible in this position can be secured without interference with the functions or position of any internal organ.

In treating cervical and upper dorsal disease in the upright position, the trunk is grasped by all available contact as a base from which to keep the head upward and backward. In disease of the mid-dorsal region, also, such traction as is possible is made on the upper mass upward and leverage is applied. That is, forward pressure is made on the diseased part and backward pressure on the spine above and below. In disease lower down, the burden to be supported is so hopelessly great and the pedestal so encroached upon that leverage—forward pressure on the kyphos and backward pressure on the parts above and below—is all that is usually attempted.

In dorsal disease we are dealing, not with the spine alone, but with the thorax of which it forms a part. Disease of the mid-dorsal region has always been regarded as the most unsatisfactory to treat. Various explanations, such as the curve of the spine and the movements of the ribs, have been offered, but it is very largely due, I believe, to the fact that although chest distortion is a conspicuous feature of the developed deformity, the parts played by the ribs and sternum in its development have not been carefully studied and antagonized. The conditions appear to be as follows: Let us take, for example, osteitis of the sixth dorsal vertebra, and for the sake of simplicity regard the bending as taking place in a circular direction around an axis passing at this level transversely through the neural canal. In Fig. 11 the normal relations of the vertebral column, upper and lower ribs, and sternum are indicated by outline and the resulting deformity in black. The spine above the axis describes a curve, at first forward then downward,

FIG. 11. Diagrammatic.—The apex of the kyphos is really lower and farther back than the same point in the healthy spine; but the development of the deformity is best shown as above.

which carries the centre of gravity of the upper mass forward. To maintain the base of the trunk (the heads of the femora) under it, the part of the spine just below the sixth dorsal vertebra is thrust forward, or, what is relatively the same, the chest is thrust backward on the lumbar spine. The lower ribs are thus tilted upward, and, from their length and normally downward slope, move the lower end of the sternum markedly forward. Were it not for the resistance of the sternum, the an-

\* The Corset: Questions of Pressure and Displacement. Robert L. Dickinson, Brooklyn. *New York Medical Journal*, November 3, 1887.

terior end of the first rib would be displaced downward to some point X, and that of the sixth upward to some point Y. As it is, the former is moved forward to B, and as the sternum turns on this point its lower end and the connecting parts of the ribs are advanced to C. The bone is commonly bent by the force transmitted longitudinally through it. In the normal relation of the parts the downward pressure of weight and muscular action exerted on the head, neck, and upper chest is borne almost entirely by the spine, the arches formed by the upper ribs, sternum, and lower ribs acting as braces. But, as the line of gravity of the mass moves forward, more of the strain is transmitted from the upper dorsal vertebrae through the braces to the spine below. The back support A D is now inclined backward and the front support B C is inclined forward. The upper mass acts as a wedge and tends to spread their lower ends still further, as the legs of a stool are spread by superincumbent weight when not tied in by the rounds. The ribs attached to the lower part of the sternum are stretched antero-posteriorly and straightened, and their relations to the vertebrae into which they are inserted are altered. The lower chest is elongated antero-posteriorly and contracted laterally. The respiratory movements of the ribs are two—upward and by lateral rotation. By tilting upward and by straightening both are greatly impaired. The sinking of the thorax on the abdomen causes diaphragmatic respiration to be also interfered with.

When the deformity is fully developed, the inclination of the spine above the kyphos is so nearly horizontal that pressure to be used on the upper dorsal spine at a mechanical advantage—that is, at a right angle—would have to be applied within the chest (as indicated in Fig. 12

Fig. 12.—Tracing from a case of advanced dorsal disease. The arrows A B show how support should have been applied to prevent the deformity.

by the dotted arrow) and almost vertically upward. The upper front of the chest is also so nearly horizontal that backward pressure can not be made on it. By placing one hand on the projecting sternum and the other on the kyphos, and pressing them strongly together, I have observed in such a case that the breathing became less short and the patient expressed a feeling of relief. There was no attempt to take off the weight, I simply made sagittal compression. The outlines of this figure

are reproduced from tracings of a case of marked dorsal deformity. The direction in which force must be applied to restore the parts to their normal relations, were that possible, shows how it must be exerted upon the normally related parts to prevent such deformity. It is essential that the pressure be applied as indicated by the arrows A and B. Referring again to Fig. 10, if pressure be confined to the upper front of the chest, the forward protrusion of the lower part is not prevented; whereas pressure on the latter exerts, through the lower ribs, a leverage on the spine below the disease, and tends to maintain the normal curvature and respiratory functions of the ribs. It also permits backward pressure at the upper part of the chest to be effectual on the upper dorsal spine. Thus, besides the general principles of support to the spine, the special indications in preventing deformity in disease of this part are antero-posterior pressure between the diseased portion and the front of

Fig. 13.—A modified Taylor back brace. Fig. 14.—The author's front brace.

the chest, especially at the lower part, and the avoidance of lateral pressure on the ribs. They must be free to curve out laterally and the viscera have space and not be compressed. Upward pressure on the free borders of the ribs also is obviously contraindicated.

For the treatment of Pott's disease in the upright position, I use posteriorly the Taylor brace, with some slight changes (Fig. 13), and anteriorly this rigid brace (Fig. 14). Since its first application, in 1892, it has been modified in several details. Commencing with the lower end, it presents a steel band passing across the abdomen and well around the sides of the pelvis, as low as is possible, without being displaced when the patient sits. The anterior superior spines are protected by thick pads

Fig. 15.—Plan of pelvic band of front brace. A, B, uprights. C, D, flat pieces extending downward. The dotted line indicates the line of the abdomen when the patient is supine.

of kersey and leather, and the central part of the band is arched forward so as to prevent pressure

on the abdomen. When the patient is supine there should be a space of one and a half or two inches behind the band (Fig. 16). It is essential that it should bend sharply around the front edges of the ilia, and fit tightly against the sides of the pelvis

for an inch or two; otherwise the skin overlying the spinous processes will become sore. I have recently improved the brace by extending the ends at a right angle downward for one or two inches. This permits the horns of the U-shaped hip band behind to be brought lower, and so increases the length, and, consequently, the leverage of the posterior brace. This leverage is of great importance in all cases where the

FIG. 16. The front brace modified for a woman or girl.

kyphos can be used as the fulcrum, and the upper mass can be successfully grasped. By means of straps at the ends the lower front band is connected with the hip band of the posterior brace, and the pelvis may, for the purpose of vertical support, be literally clamped between the two, which nearly meet at the sides. At the location of each anterior superior spine a flat upright is riveted at right angles, or, if the abdomen is very protuberant, the uprights are directed outward from the lower band. The curving of the band permits them to be approximated above. They extend upward and inward along the abdomen and chest to the infraclavicular spaces. At the level of the axillæ they are crossed by a flat band which passes in front of the chest and nearly through the axillæ at each end. Three holes drilled in the uprights, three eighths or half an inch apart, will save trouble in placing the band. Or the uprights may be made in two pieces overlapping and fastened by screws, so as to be readily shortened or lengthened. The chest and pelvic bands may also be made extensible. The pelvic bar should be an inch, the others half an inch wide. No. 16 spring steel is a good material for the construction of all parts. These dimensions are for children. It will be convenient to have the separate parts covered with leather and then fitted and fastened together. In measuring, one is apt to locate the chest band too high as well as to make the entire front brace too tall. It is very instructive to note how far the anterior chest wall will, notwithstanding all possible pressure, descend when in the upright position. It confirms what has been stated concerning the mechanical advantages of the supine posture with reference to traction, and demonstrates the hopelessness of

attempting more with vertical traction than to partly support the head and take off some of the weight of the upper extremities. At the upper ends of the uprights are straps which pass over the shoulders to buckles on the shoulder pieces of the posterior brace, and from the ends of the chest bands straps running backward buckle to the crosspiece. This crosspiece extends nearly to the posterior edges of the axillæ. Placed behind the upper part of the front brace is a stiff leather perforated chest piece, which is secured to uprights and covers the front of the thorax as far down as the ensiform cartilage. I usually have this fastened by the same rivets which fasten the chest bar to the uprights, and support the upper and lower edges of the leather by straps and buckles from upright to upright. Near the lower ends of the uprights are padded web straps which extend over the crests of the pelvis to the buckles on the spinal uprights behind. Their utility is dependent on pelvic development. They and the hip band of the posterior brace afford all the vertical support anatomically possible. The ends of the bar passing through the axillæ may be padded as crutches, or from the ends of the shoulder pieces the regular, round, padded shoulder straps of the Taylor brace may pass through the axillæ and back to a second crosspiece placed just below the first. The perforated chest piece can be made to fit accurately by binding it, while wet, to the chest, oiled silk being interposed. This is not usually necessary.

In high dorsal and cervical cases I prefer, for vertical support, the Taylor head piece without the ball-and-socket joint, the slipping of which is a constant annoyance. In place of the joint I use a pivot, flattened below, to slide in a keeper fastened to the uprights. This pivot has a soft neck which can be bent easily in any direction, and is, I believe, the original device of Dr. C. F. Taylor.

Thus constructed, this combination of anterior and posterior braces constitutes a skeleton support to which parts may be added to meet the individual requirements of a peculiar case or the special views of the surgeon. Should a greater area of lateral support be required, it can be secured by a series of straps from the anterior to the posterior uprights. I think, however, that in Pott's disease, lateral curvature from muscular spasm is best treated by recumbency, and lateral pressure on the chest should be avoided. Although all available space has been utilized for the application of both traction and leverage in diseases of any part of the spine, it is applicable especially to dorsal disease. When the spine above the kyphos is still nearly vertical, the backward pressure exerted at the top of the sternum and the upper ribs serves to directly repress its forward tendency, and by pressure at the lower part of the sternum and connecting ribs the forward protrusion of the front of the chest is antagonized.

An illustration of how this apparatus may be modified to meet diverse mechanical requirements is found in its application to girls and women, and another in its

use in those cases of extreme deformity of chest and spine previously described. That shown in Fig. 17 was made for a woman with high cervical disease. The area of desirable pressure being restricted by the breasts, the leather chest piece is limited to the upper part of the thorax. Instead of placing the steel band directly across the chest, it is shortened, placed just under the clavicles, and at each end connected with a broad, curved piece of sheet steel extending through the axillæ. The uprights have been located farther back, and the front ends of the padded straps, which rest on the crests of the ilia, have been transferred to the pelvic band. This attachment and the extension downward of the ends of the band, previously described, are suggestions of my colleague, Dr. J. M. Clayland. The lower edge of the leather chest piece is secured to the steel on either side by strap and buckle. In dorsal disease the leather chest piece is extended downward in the middle and connected with the uprights by a steel bar arching over each breast, and having at its ends straps to buckle around the uprights. It is not well to fasten the brace rigidly together in too many places because it interferes with modification.

For the case outlined in Fig. 12 the posterior uprights reach only as high as the summit of the kyphos and the front brace to just above the protuberance of the sternum (Figs. 17 and 18). No part of the apparatus pass-

FIG. 17.—The front and back brace for a case of advanced dorsal disease with chest deformity.

FIG. 18.—The front brace for a case of advanced dorsal disease with chest deformity.

es over the shoulders, and care is taken that the ribs be not compressed laterally. Two crosspieces were placed in the posterior brace and thus two connections made with the anterior. Although the upper crosspiece tends downward to the axilla the pull upon its end is forward. A small pad was placed on the projection of the chest, and antero-posterior traction made between it and the dorsal projection. The prominent hips are utilized for vertical support exerted against the lower side of the kyphos. There is no pressure exerted above the kyphos, nor above the apex of the chest deformity. The leverage

of a posterior brace is not applicable because grasp on the upper spine is not possible. It had sunk into the chest so far that it can not be successfully pushed against by pressure on the upper ribs or pulled against by traction on the head, and no adequate base for vertical traction on such a mass as that above the kyphos exists.

For the sake of clearness, the braces are shown as if applied to the skin. They are worn over an undershirt. It will be found convenient to cut the garment all the way down the front and put this part behind. The patient should be laid on his face twice daily, the back brace removed, and all pressure points bathed with alcohol and water and dusted with talcum or some such powder. The brace should never be taken off or put on when the patient is upright.

To diminish the concussion of walking I use shoe heels of soft rubber. They are to be attached without nails and have the front edge beveled to prevent catching.

The apparatus described can be made by any blacksmith, and with a pair of wrenches can be fitted and modified to meet the changing needs of a case. While some time and care must be devoted to its application, the mechanical indications once thoroughly understood, this is not so difficult as it may seem, and when the serious nature of the disease is appreciated, the first consideration is that of adequacy, and the last that of ease to the surgeon. In all orthopædic cases, particularly in Pott's disease, there is to be recognized a broad working principle that an apparatus is simply a tool to be designed and used with intelligence. The surgeon owes to the patient a careful determination of the conditions present. They may usually be met by the simplest means, and the duty of meeting them is the surgeon's.

To refer a patient with tuberculous disease of the spine to an instrument-maker who knows nothing of the intrinsic nature of the case is as great a crime as to send a case of typhoid fever to an apothecary. The law protects the typhoid but not the tuberculous. When it does the latter, the sight of a patient whose diseased spine, entirely unable to bear its own strain, is further burdened by a glittering complication of steel and leather, will be no more.

498 BEDFORD AVENUE.

## THE RAPID BACTERIOLOGICAL AND CLINICAL DIAGNOSIS OF DIPHTHERIA.

By HENRY KOPLIK, M. D.

FROM a clinical standpoint the rapid and satisfactory diagnosis of diphtheria, fortified by bacteriological culture test, is of the utmost importance. It is highly desirable in every case to satisfy our minds, as early as possible, whether the disease we are dealing with is that in which the Klebs-Loeffler bacillus is present or in which we have simply a streptococcus diphtheria or, if possible, a mixed infection. Clinically it has been am-

ply demonstrated that the types of angina in which the Klebs-Loeffler bacillus is found do not include simply the membranous formation. We have all gradations of angina, from the throat in which membrane is absolutely absent, to that in which the fully formed membrane exists (Escherich, Koplik, Feer, Park, Flexner, Welch). With our present methods of therapy and the demands of prophylactic hygiene, it has become more and more imperative to shorten the time within which a positive bacteriological diagnosis of the nature of a given case of angina or membranous formation in the throat may be made (true diphtheria of Loeffler, or diphtheroid angina). It is also desirable to have a simple method, a rapid and easily attainable means of diagnosis, within the reach of the general practitioner, not only in out-of-the-way communities but even in large cities. In the latter places, in spite of the presence of well-equipped health stations, economic and hygienic reasons are tending to compel every physician to acquaint himself with the technique of the early diagnosis of diphtheria.

I have made a series of studies with the ordinary serum tubes with a view to fixing the shortest space of time within which a diagnosis of true Loeffler diphtheria may be made beyond a reasonable doubt. I am now able to fix this time by tube culture at two and a half to three hours from the time the tube-culture medium is placed in the incubator. As is well known, if we take a piece of membrane or secretion from the tonsils or fauces of a suspected case of diphtheria and spread this in the usual way between two cover glasses, stain with Loeffler's blue solution and examine, we see, if the case is one of Loeffler diphtheria, a few isolated bacilli here and there having the characteristic form and stain of the Loeffler bacillus. In a vast number of cases the diagnosis, even if membrane is present, remains a matter of speculation on account of the paucity in the numbers of bacilli and the absence of the characteristic grouping of these bacilli, to which we will refer at length. In cases of diphtheria of the larynx, or even of the fauces, in which there is absolutely no visible membrane, a diagnosis by cover glass is impossible. It is in just such cases that an early and rapid diagnosis is most desirable. Moreover, I am convinced that the methods now most in vogue, by which the culture tubes are allowed to remain in the incubator fully eighteen hours or twelve hours, give the ubiquitous streptococci and staphylococci sufficient time, at an elevated temperature and such a favorable medium as blood serum, to outgrow the bacillus diphtheriae in numbers, and thus obscure the final diagnosis if, indeed, it does not make it impossible. It is true, as Loeffler first showed, that the serum remains the best medium for the cultivation of the bacillus diphtheriae, for on this medium alone can the bacillus hold its own against the growth of other bacteria. Yet there are many cases in which we only succeed in obtaining a relatively small number of the Loeffler bacilli on our swab, as compared with the streptococci, and in the

serum tube. It is just in these cases, as will be seen, that the early diagnosis shows the bacilli to be present, whereas after twelve to eighteen hours the streptococci or staphylococci will have outgrown them and obscured the diagnosis. This must account for the number of cases in which no result is attained by the old methods in which pronounced membrane is present in the fauces.

As has been intimated, the medium which I have employed in my studies to cultivate the bacillus diphtheriae for clinical diagnosis is blood serum, for after all has been said it is the most convenient and certain medium, and may not be easily replaced in the future by anything more favorable to the growth of the bacillus diphtheriae. During the first hours of the sojourn of the serum-culture tube in the incubator it can be seen that the bacillus diphtheriae not only thrives but does this at a rate exceeding that of the other bacteria. But the streptococci present in any given case must vary largely. Therefore, in the early stages of the culture, even if the streptococcus in material numbers surpasses that of the bacilli, the bacilli increasing in numbers still can be easily diagnosticated. Later on, if the bacilli are few in number, the streptococcus growth spreads so rapidly over the surface of the serum as to obscure or cover the bacilli in certain cases.

The sterilized swab on the end of a stout wire, as now in general use in New York, is the most practical means of taking the specimen of secretion or membrane from the throat.

**THE INCUBATOR.**—As an incubator, a small water oven is used, the interior chamber of which measures  $4 \times 5 \times 6$  inches—

just large enough to accommodate small or large test tubes. The whole is mounted, as shown in the accompanying cut, on an ordinary retort stand. It is supplied with a thermometer which is fixed in the central opening and shows the temperature of the interior. It may be supplied with a small thermometer at the lateral opening showing the temperature of the water, but this is hardly needed. It will be seen that the oven

is of the most primitive construction, and can be obtained in all supply stores; it is not armed with an exter-

nal felt or asbestos coating to prevent radiation, as the short period of its use scarcely calls for this precaution. The simplicity will speak for its use in the physician's office laboratory, especially as it can be taken apart and put up at a moment's notice. To prepare the oven for use, it is filled with water, or kept so prepared; the temperature of the internal chamber is raised rapidly to 37°–38° Celsius by means of a Bunsen flame—this takes about five minutes; as the temperature reaches 37° the flame is taken away, for the temperature continues to mount to 38° C., and at this point a small oil lamp, as shown in the cut, replaces the Bunsen flame. The lamp, turned quite low, will maintain the internal temperature quite constant at 38° for any length of time. For three hours' heating we need scarcely disturb the flame, as it takes care of itself. For longer periods it may need occasional watching.

**METHOD OF PROCEDURE.**—The patient is placed facing the light. A tongue depressor having brought the fauces into view, the sterilized swab is rubbed gently over the suspected membrane or patch in the throat, or even the inflamed tonsils where no membrane exists. The swab is then carefully and evenly rubbed on the slanted surface of the blood-serum culture medium in the test tube.

The inoculated tube is then placed on the floor of the oven in a horizontal position. This is done in order that the glass tube and culture medium may become rapidly warmed to the temperature of the internal chamber of the incubator. If this culture tube is taken out at the end of two hours and a half, we can see by means of a magnifying glass that the surface of the serum has already become coated with a distinct growth of minute bacterial colonies, both in the Loeffler bacillus cases and those cases in which streptococci or staphylococci are present. At this early stage all the colonies, whether streptococcus or bacilli colonies, have the same transparency, and can not be differentiated as they can after twenty-four hours' or eighteen hours' growth, when the colonies of the bacilli of Loeffler have a whiter appearance as compared with those of the streptococci.

At the end of four hours the growth on the surface of the serum is perceptible even to the naked eye. It can be perceived if the serum is held between the light and the eye as a thin film on the surface of the serum, if the latter is transparent enough. At the end of five hours the growth is a very palpable one. From a clinical standpoint the culture gives diagnostic and very satisfactory results when examined at the end of two and a half to three hours. These results are not improved upon, as will be shown by the results obtained by a longer sojourn in the incubator. The bacteria have only increased in numbers. In some cases it will be shown that to wait puts us at a distinct disadvantage.

The surface of the serum, which has been taken out of the incubator at the end of two hours and a half or

three hours at the latest, is now carefully scraped with a sterilized platinum wire bent at its extreme point into a minute crook. The scraping is made in a longitudinal direction and should include, if possible, all the surface where we think the growth has occurred. No attempt is made to pick out any colonies. The scrapings are then spread on a cover glass with a drop of water, in the usual manner. The specimen is dried in the flame and stained with the Loeffler alkaline blue.

**THE OPTIMITY OF GROWTH OF THE KLEBS-LOEFFLER BACILLUS.**—It has been shown by Roux, in his very early work on diphtheria, that the bacillus diphtheriae attains its greatest luxuriance of growth in artificial media below the temperature of 39.5° C. At this temperature, however, and above it, the bacillus shows a diminished vigor, and in a few days it ceases to grow. At 40° the retarding effect of the elevated temperature is more distinctly apparent.

In my studies I found that the best results are attained if the temperature of the internal chamber is kept ranging from 37° C. to 38° C. Above this temperature the serum does not show a satisfactory growth of bacilli, and these bacilli show the swollen and clubbed forms more distinctly. The involution forms are more common at the temperature of 40° or above. The growth, however, of bacilli is less vigorous than that of the streptococci or staphylococci at 40° or 41° or 42° C. The method, therefore, of procedure is to force the Loeffler bacilli to increase rapidly in numbers at a temperature corresponding to their optimity of growth, 38° C.; not to overstep this point, and yet not work below 37° C.

#### CLASSES OF CASES IN WHICH THIS METHOD HAS BEEN FULLY TESTED.

**CLASS A: CASE I.**—Laryngeal symptoms, no visible membrane, laryngeal cough and breathing. Male infant, a year and a half old, sick for three days with croupy cough and breathing. Retraction at each inspiration of the episternal notch and peripneumonic groove; consolidation of the apex of the left lung (pneumonic); no membrane. Culture in incubator an hour, no diagnosis; culture in incubator two hours, streptococci; culture in incubator four hours, groups of Loeffler bacilli in abundance. Tube in incubator eighteen hours: the streptococci had overgrown the bacilli so that the latter were not apparent, as in the four-hour specimen. Thus, between the second and fourth hour bacilli were produced in sufficient numbers to enable a diagnosis.

**CLASS B. LACUNAR DIPHTHERIA OF THE TONSILS: CASE II.**—Boy, aged five years and a half, sick with fever; croupy cough for three days; tonsils enlarged; the lacunar plugs evident; no membrane. Some of the plugs quite large. Culture in incubator three hours: almost pure culture of Loeffler bacilli; culture in incubator eighteen hours (overnight): bacilli only more abundant.

**CLASS C. MEMBRANOUS CASES: CASE III.**—Boy, aged three years; yellow-white membrane on the left tonsil; no other history. Culture in incubator an hour, no positive diagnosis; culture in incubator two hours,

abundant Loeffler bacilli; culture in incubator four hours, abundant Loeffler bacilli; culture in incubator eighteen hours, streptococci more abundant, yet bacilli abundant also.

CASE IV.—Boy, five years and a half old, has been ill three days with symptoms of a severe sore throat. Right tonsil is covered with a grayish coating. Culture in incubator two hours and a half, pure culture of Loeffler bacilli; culture at end of eighteen hours, same bacilli, only more abundant.

CASE V.—Boy, three years old, has been ill only one day with fever and a sore throat. Both tonsils are covered with a greenish membrane. Tube in incubator at 41°-42°, after three hours we find Klebs-Loeffler bacilli in abundance. There are numbers of involution forms—swollen, club-shaped bacilli of uneven stain. Culture after eighteen hours showed that the bacilli had been outgrown by the streptococci; no bacilli found in specimens examined.

CASE VI.—Female infant, a year and eight months old, ill one day. The left tonsil coated with a greenish membrane, but slight adenitis. Culture in incubator two hours and a half, almost a pure culture of Klebs-Loeffler bacilli, few chains of streptococci; culture after eighteen hours (overnight), diphtheria bacilli predominant, few streptococci.

CASE VII.—Male child, two years and a half old, ill one day. Both tonsils covered with a greenish membrane, slight adenitis. Culture in incubator two hours and a half, Klebs-Loeffler bacilli in numerous groups, few streptococci; culture after eighteen hours, Klebs-Loeffler bacilli still more abundant, streptococci few.

CLASS D, CASES OF ANGINA WITH THE EXANTHEMATA: CASE VIII, MEASLES.—Female child, three years and a half old, just recovering from measles, pigmented mottling of skin still to be made out. For the past three days has had a croupy voice and cough. Tonsils enlarged but no membrane to be seen. Culture in incubator two hours, streptococci; culture in incubator four hours, streptococci; culture in incubator eighteen hours, streptococci.

CASE IX, SCARLET FEVER.—Female child, four years and a half old, has been ill for the past three days with slight diarrhoea and vomiting. There is a febrile movement; a slight efflorescence on the upper part of the chest; a marked tonsillitis, with a membranous formation, on the left tonsil. Diagnosis: scarlet fever and diphtheria. Culture tube in incubator two hours and a half, streptococci; culture tube in incubator four hours, streptococci; culture tube in incubator eighteen hours, streptococci.

CLASS E, CASES WHICH ARE NOT CHARACTERISTIC: CASE X.—Female, seven years old, has been ill with symptoms of angina one day. There is a yellow plug quite large in the left tonsil. Culture in the incubator two hours and a half, staphylococci; culture in the incubator eighteen hours, staphylococci; no bacilli in early or late culture.

CASE XI.—Female child, two years and three months old, sick for three days with a nasal discharge and sore throat; tonsils quite large; uvula coated with a hazy, bluish pellicle at the base; no distinct membrane; test taken from tonsils and uvula. Culture in incubator two hours and a half, streptococci; culture in incubator four hours, streptococci; culture in incubator eighteen hours, streptococci.

CASE XII.—Male infant, thirteen months old, has, enlarged tonsils and streaks of yellow mucus on the

tonsils; no distinct membrane. Culture in incubator three hours, streptococci; culture in incubator four hours, streptococci; culture in incubator eighteen hours, streptococci.

CASE XIII.—Female, aged five years, has for some days past had a discharge from the nose. There is a bluish-white discoloration inside the right nostril, like a thin pellicle. Tonsils show lacunar plugs, left tonsil a grayish coating of mucus. Cultures from nose and throat in incubator two hours and a half, streptococci; culture in incubator eighteen hours, streptococci; no bacilli found.

CASE XIV.—Female child, three years old, has been ill with cough and sore throat three days. The left tonsil shows a yellow spot; no distinct membrane. Culture in incubator three hours, streptococci; culture in incubator four hours, streptococci; culture in incubator eighteen hours, streptococci.

CLASS F, SURGICAL WOUND DIPHTHERIA: CASE XV.—Female child, three years old, suffering from a large granulating surface on the left buttock, the result of a severe burn. This surface had become coated with a thick, yellow, tenacious material, in some places dry and of a greenish hue; in places it looked like a pseudomembrane. Culture tube in incubator two hours and a half showed a very luxuriant growth of bacilli not in any way resembling the Klebs-Loeffler bacilli.

DIAGNOSIS.—In order to fix a diagnosis, we have required in all cases, in addition to general character of size, etc.—

(a) An abundant bacterial growth, not isolated bacilli.

(b) The characteristic grouping of the Klebs-Loeffler bacillus in groups of pairs or fours, side by side, or more so arranged.

(c) Peculiarities of unevenness in staining with Loeffler alkaline solution of methyl blue.

(d) The presence of involution forms, club shapes, etc.

If the reader will refer to Cases I and V he will see that the contention of the writer in the first part of this paper, concerning the desirability of making a diagnosis early in the culture growth, is well founded, especially in cases (as Case I) where no characteristic membrane was present in the fauces. Here it must have occurred that but few bacilli were introduced by the swab into the serum tube as compared with the relatively enormous streptococcus material on the swab. The tubes examined early showed quite plainly, and without any reasonable fault, distinct groups of Klebs-Loeffler bacilli, fully convincing for a clinical diagnosis. These same tubes, examined after a prolonged incubation, showed streptococci or other bacteria. The bacilli, if present, could only be found by prolonged search. The streptococcus material was clearly so abundant that though starting on an equal basis, or rather at a disadvantage, it had finally at an advanced temperature and additional time overgrown the bacilli.

Our method, which will apply to the difficult as well as the apparent cases of diphtheria, is to force the in-

crease in number of the Klebs-Loeffler bacilli at the highest temperature favorable to them, 37° to 38° C., and to examine the culture tube two hours and a half to three hours after placing in the incubator. The streptococci and staphylococci and sarcinae have then as yet not attained considerable growth, and the Klebs-Loeffler bacilli, if present, can easily be found.

66 EAST FIFTY-EIGHTH STREET.

## THE CONSERVATIVE TREND.\*

By JABEZ N. JACKSON, A.M., M.D.,

PROFESSOR OF ANATOMY AND ADJUNCT PROFESSOR OF SURGERY,  
UNIVERSITY MEDICAL COLLEGE, KANSAS CITY, MO.

A CRITICAL review of the progress of surgery during the past year impresses one with the fact that it has been a period not so much of innovation and discovery, but rather one of deliberation and development. The work of the past decade in surgery has been both voluminous and brilliant. The dawning of the new era of antiseptics and asepsis has been followed by most startling achievements. The danger of sepsis and its correlating conditions, which ere this time rose as a black nightmare before the vision of Ambition, had limited surgery to a comparatively narrow part of the great science of healing. Before the immortal discoveries of the great Sir Joseph Lister, however, in one moment the forbidding walls were laid low. Fields of investigation hitherto looked upon only as *terra incognita* now became the scene of busy activity in surgery. Pathological conditions which had previously baffled the wisest counsel and most ingenious devising of medicine now invited the efforts of the new surgery. Enthusiasm naturally ran wild, and with neither chart to guide nor theory to control, experimental surgery began its new career. Before each aspiring surgeon lay open rich fields of unexplored wealth, with visions of fortune and eternal fame awaiting his command. Each man a pioneer and none a guide was truly an enticing opportunity. The work of the past decade has naturally, therefore, been more fraught with discovery than that of any which had gone before—nay, perhaps, than that of all which had gone before—and gives it rank in history as the golden age of surgery. Many of its achievements have brought inestimable good to the human race, and paved the way for surgery to its recognition as one of the grandest and noblest of all the sciences and arts.

It is not my purpose in this paper to detract in the least degree from the high measure of praise and commendation due to the surgery and to the surgeons of the decade that is gone. As, however, the explorer of all new lands, unguided by experience, commits errors apparent to his retrospection, so surgery in its new work has with enthusiasm advanced some doctrines which its

present wisdom and experience must lead it to discard. The collection of data must precede the classification and establishment of any true science or the enunciation of fixed principles arising therefrom. These years which have gone before, therefore, have been invaluable in the collection of vast elements of advanced truth.

The past year, though indeed largely barren in new exploration, must likewise be considered as time most wisely spent in the critical analysis of the facts already adduced and in the deduction of sound principles for future work. This is the time of reckoning, and we should now be able to in a measure weigh our discoveries and ascertain the true relation of surgery to the problems of human life and human happiness. The result of these deliberations has demonstrated to us many excesses of our zeal and led to a decided trend toward conservatism in surgery; not that conservatism, however, which but masks the face of ignorant inactivity, but a truer and higher conservatism which puts life first, then function, and finally form.

In the limited confines of this paper it would be manifestly impossible for me to indicate the scope of this conservatism in all the departments of surgery. I shall therefore confine my remarks to some of its applications in various affections of the great cavities, since it is in this realm that radicalism has been most marked and has done the greatest damage as well as the greatest good.

### BRAIN SURGERY.

We are to-day just emerging from an inundating tidal wave of brain surgery. Within the past few years there has been scarcely a pathological condition to which the brain is subject that has not been submitted to the trial of operative surgery for its relief. Medical skill had for years exercised its best efforts for the cure or control of diseases of cerebral origin, and, in a vast majority of conditions, with but limited or no success. With great expectation and hope, therefore, the profession turned its thoughts to the possibility of relief by surgical measures. In this department of work has been enlisted the services and talents of many of the most distinguished members of the brilliant mass of modern surgeons, aided and counseled by the most eminent neurologists throughout the world. True it is these labors have brought to us knowledge of inestimable value. Cerebral localization and an accurate understanding of much of the physiology and physiological anatomy of the various portions of the brain are achievements which have placed medicine upon a scientific and accurate basis in the diagnosis of cerebral pathology, and shall forever stand as a brilliant record to the credit of brain surgery. But how disappointing, alas, have been all our efforts when viewed from the standpoint of therapeutic value!

EPILEPSY.—The possibility of relieving the distressing and heretofore largely hopeless cases of epilepsy, for instance, how eagerly and even enthusiastically it was embraced! The theory that all epilepsy of cerebral ori-

\* Address as Chairman of the Committee on Progress of Surgery of the Missouri State Medical Association, at Sedalia, Mo., May 20, 1896.

gin was attributable to local excitation, and that the removal of the offending cause would insure a disappearance of its ensuing clinical manifestations, seemed indeed logical, both in its premises and in its conclusions. All forms and degrees of epilepsy, whether general or focal, have been, therefore, subjected to varied operative procedures. The temporary benefit following nearly all operations for a short time led us at first to believe that we finally had found the happy solution of this vexatious problem. How limited, alas, have the ultimate results proved our power! In general epilepsy it was soon demonstrated that nothing is to be expected from surgical intervention. This, however, has occasioned no great surprise, as little rational hope was ever entertained for this class of cases. Even in focal, cortical epilepsy, however, dependent upon a distinct and localized lesion susceptible of removal, the history of our work shows a sad lack of permanency in results. As Eulenbarg says: "By the excision of an area of the cerebral cortex the attacks may be made to stop for a short time; but they return after a while." Von Bergmann further asserts, that "only those cases of cortical epilepsy are cured by trephining which are due to tumors, especially cysts, which are often the results of intrameningeal exudations due to traumatism over or within the circumscribed motor area." Nancrede also affirms that his experience, like that of Horsley, Keen, and other surgeons, has demonstrated a lack of permanency in results, and looks upon the removal of the discharging lesion in cortical or Jacksonian epilepsy as a merely palliative procedure. He further observes that "the earlier the operation is done after disease has become established, the longer the immunity," and adds that "it is possible that if trephining were resorted to early, the operation in a few instances might prove curative, if a reliable method were devised to prevent the inevitable scar, and the adhesions between the brain and its meninges." Universal experience, however, demonstrates that after degeneration of nerve substance has set in, it is too late for surgery.

We may remove the primary cause; but the degeneration, which is the secondary and efficient cause of epilepsy, is beyond our control with present methods. One vastly important observation, however, has been impressed upon the surgeon's mind by his experience in the surgery of epilepsy—namely, that a large percentage of the cases of epilepsy are due to remote traumatism of the skull, either unrecognized at the time or, if recognized, improperly handled. The significance of this observation should not be overlooked in dealing with any injury about the head, and I confidently believe that the true conservative surgery of traumatic epilepsy is the radical surgery of the trauma. With Lanphear I can quite agree in the aphorism that "the way to cure traumatic epilepsy is to prevent it."

IMBECILITY AND IDIOCY.—The operative treatment of imbecility and idiocy has also proved a complete failure. As Dana has aptly said: "This operation was origi-

nally devised on the theory that by cutting open the skull of the microcephalic child, opportunity was given the brain to grow. This theory, which was never substantiated by facts and never held by any experienced neurologist, has been, of course, overthrown. . . . What the operation does is this: It has a profoundly disciplinary effect upon the idiot. . . . The operation of craniotomy upon children in institutions attracts the attention of nurses and of all the medical officers, and the children get more care and more stimulating words of help in various directions. I would repeat, therefore, that it is in my opinion largely due to its pedagogic influence that an improvement in these cases takes place, and that the operation is allied in its effects to a severe piece of castigation." Many surgeons have, however, justified and praised this character of work on the ground that, in view of the absolutely hopeless and practically helpless condition of these unfortunates, their lives were but a burden to their friends and a mere blank to themselves.

The moral side of the question has been apparently lost from view in our excessively utilitarian tendency. In his masterly address on surgery before the recent meeting of the American Medical Association, Semm very beautifully and forcibly draws attention to this subject in the following language: "I am free to confess that I have never been able to muster my courage to attack the skull of a poor microcephalic child, because I have always regarded the operation as useless in promoting brain development. The responsibility of the surgeon is not limited to the defective mental development of the child nor the importunity of the parents in demanding an operation at all hazards. The surgeon should stand guardian over such a charge, mindful of the limits of the art of surgery. Have we a right to estimate human happiness? The driveling idiot has many enjoyments that you and I know nothing about. His responsibilities to God and man are limited and his existence on earth is a long, happy dream, which only ceases when the soul leaves the imperfect body and returns from whence it came, where mental distinction is unknown."

#### ABDOMINAL AND PELVIC SURGERY.

In abdominal surgery, perhaps, the most brilliant advances in operative work have been recorded. The surgery of this cavity has been simply marvelous when we consider the short time in which it has all been accomplished. The invasion of the abdomen prior to the enunciation of the principles of antiseptics was a venture hazarded only under conditions of most exacting necessity, and then with fear and trembling by even the boldest of surgeons. How marvelous the change, when now the operation is of almost daily occurrence in the practice of surgeons of eminence, and by many declared a safe and wise procedure even for exploration and diagnosis! Has not our enthusiasm here also carried us beyond the limits of scientific rationalism, and made surgery in many

instances more a matter of mechanical dexterity than of mature judgment and wisdom?

The present trend of surgical opinion certainly appreciates this as a fact. While the conscientious surgeon should not now hesitate to open the abdomen under any circumstances of accurate indication, yet he must, if he be true to the teachings of experience and honest in his relations to his reliant patient, remember that the opening of the abdominal cavity is not absolutely free from much danger even in simple cases in the hands of trained operators, and under strictest precautions. The old axiom, "Be sure you are right and then go ahead," is worthy the memory of the scientific-surgeon even to-day. Let us be thankful that the brain is once more to be recognized in surgery and not the hand alone.

**APPENDICITIS.**—From the many operations within the abdominal cavity I have singled out appendicectomy for a brief consideration; not because it is more important than many others, but because herein radical surgery has gone to its absolute extremes and been thoroughly tested and discussed. Just what is the proper relation of surgery to the inflammatory affections of the appendix is, in my judgment, still an open question. The insidiousness of the disease, its manifold aspects clinically, the uncertainty of the differentiation of its various forms, and the impossibility of foretelling its course, render a scientific and fixed stand impossible in the light of our present knowledge. Unfortunately, the mass of clinical observation in appendicitis scientifically recorded has been from cases surgically treated. This aspect of the disease has therefore been carefully weighed. A corresponding amount of evidence regarding the non-surgical treatment is not obtainable. True, appendicitis must have been treated for many years medically, before the surgery of the appendix was ever introduced. At that time, however, the pathology of this condition was practically unknown, and its differentiation from other conditions, such as general peritonitis, obstruction of the bowels, fecal impaction, typhoid fever, etc., was so utterly obscure that accurate data were never had, and retrospective diagnoses and records are utterly unreliable. Since its recognition as a distinct disease, on the other hand, the fashionable treatment has been so largely surgical that we are just now beginning to acquire medical statistics for scientific comparison. The result of these researches is an unmistakable trend toward conservatism. A few years ago the almost universal doctrine was "surgery alone and surgery immediately." It is to be hoped that we will never drift back to the old do-nothing course. A judicious selection of cases, however, and a correct decision as to the time for operation in the various forms, are worthy of thought and honest discussion. Says Hunter McGuire, in a recent paper on this subject: "I am not always in a great hurry to operate, but I am inclined to wait for the more acute symptoms to wear off, and operate, if at all, after suppuration has taken place or during the quiescent stage be-

tween the attacks. I wish my voice was strong enough just here to call a halt to the men who say, 'Operate at once—not this afternoon, or to-morrow, but now, in all cases when the disease is recognized.'" Concerning the class of cases for operation, Herbert W. Page says: "Increasing experience shows that the affections of the appendix which call for surgical intervention fall into two main classes: (1) those in which there is perforation by a concretion, and (2) those in which the appendix has had its lumen temporarily obstructed by kink or cicatricial contraction, so as to cause retention of mucus and feces, which lead to inflammation in and around it. The former cases are the more serious and call for early operative measures in order to evacuate local collections of pus; the latter are to be dealt with in periods of quiescence, when the disturbance of adhesions is less likely to be dangerous, and aseptic conditions can be more readily secured."

Senn very tersely summarizes his position in the following words: "The custom followed by many American surgeons, to remove the appendix in all cases in which a diagnosis of appendicitis is made, is a very harmful one. The removal of the appendix should be limited to (1) those cases in which during the first attack symptoms arise which portend danger to life, and (2) to relapsing appendicitis. Some cases of appendicitis yield to medical treatment, and in a large percentage of such cases the patients remain free from a second attack." These expressions suffice to indicate the judgment of some of our best men both at home and abroad. There are, however, many other surgeons of unquestioned ability who still retain radical views. A sound conservatism is undoubtedly desirable and will soon, I believe, be unchallenged. I have no sympathy, however, with the willful ignorance of those who state that ninety per cent. of all cases of appendicitis will get well without surgical intervention.

**EXTIRPATION OF THE UTERUS AND OVARIES.**—A few years ago I heard an able gynecologist say that "the only gynecology was surgical gynecology." His statement was in pretty accurate accord with the work of the gynecologist of that time. The long-established customs of medical therapy in the diseases of the female generative organs was practically abandoned, nay, even ridiculed, and surgery ran rank and wild. The craze for operative records seems to have clouded entirely the conscience and high moral tone of our profession. The remotest future possibility of danger alike with evident present necessity was considered justifiable indication for the extirpation of organs whose vital importance to the physical, mental, and moral welfare of woman is immeasurable. Given a pain or other evidence of disease of the female generative organs, however trivial, and forthwith the far-seeing surgeon pictured to his mind, and to that of his victim, visions of most alarming future calamity and miserable death, unless these threatening organs were at once removed. An ovarian neuralgia,

visions of pus sacs—an urgent oophorectomy. A minute fibroid, sarcomatous degeneration—hysterectomy. How many a woman in apparently absolute health and with prospects of a long and happy life before her has found a premature grave from our surgical zeal! How many more have on slightest or no provocation been unsexed and unstrung! Is it not time for the manhood as well as the science of our profession to call a halt to such work? To their credit be it said, many of the leading gynecologists are themselves beginning to sound the note of retreat; and nothing is more apparent in the literature of pelvic surgery in the past year than a distinct trend toward scientific conservatism.

In the recent edition of the *American Yearbook of Medicine and Surgery*, under the head of Diagnosis of Pelvic Inflammatory Diseases, occurs the following expression: "The profession at large is awakening to the fact that a very large proportion of tubes and ovaries are annually uselessly sacrificed either to an absolute inability on the part of the operator to recognize the true condition, or to a culpable neglect on his part to accomplish an absolute diagnosis."

How often has a laparotomy been made with but the slightest effort to ascertain the condition present; and when perfectly healthy, or at the furthest but slightly damaged organs were found, they were nevertheless removed lest they cause some subsequent trouble, and to justify to the patient the ignorant and careless work of the operator, who must show some trophy of his butchery! In the light of these facts it is a gratifying indication to receive from the pen of so well-known a gynecologist as Howard A. Kelly, of Johns Hopkins University, the following expression: "Conservatism is undoubtedly the progressive spirit of gynecology; exsective and amputative gynecology has gone to its extreme limits, and the more thoughtful surgeons looking at all the questions involved, in their broader aspects, have already sounded the keynote of the new advance." The rule for operative interference in fibroids given by Mr. Champneys, president of the London Obstetrical Society, may well be given a broader application to all conditions indicating radical procedure. Says he: "The number of cases in which operation is justifiable or desirable must, generally speaking, be regulated by the ascertained risks of the tumor [or disease] against the ascertained risks of the operation; the former must exceed the latter before operation could be justified." Life must be reckoned as the first object of our care, to be hazarded only on most certain indications.

But not alone in the decreasing number of capital operations has conservative thought manifested its influence. The second care of true conservatism is in the preservation of function. The rapid multiplication of more conservative methods and measures in operating is in line with the recognition of this principle. If surgery be indicated at all, let it be the simplest and safest and the least disturbing to function

consistent with the subsequent welfare of the patient, is a doctrine which certainly appeals to our judgment as well as to our conscience, and at last we are beginning to appreciate its weight. Among these conservative measures, replacing more radical ones, may be enumerated the following, as cited by Kelly in the paper above alluded to:

1. Resection of diseased ovaries and opening and draining tubes, instead of extirpation of these organs (Polk).

2. Myomectomy as a substitute for hysteromyomectomy (Dudley).

3. Opening and draining pelvic abscesses, posterior to the uterus, through the vagina instead of by the abdominal route (Henrotin).

4. Vaginal drainage in some cases of extra-uterine pregnancy in place of abdominal extirpation (Kelly).

5. Excision of both large and small parovarian cysts without sacrificing ovary and tube (Kelly).

And to these might be added—

6. Curettement and packing of the interior of the uterus in all cases of subacute or chronic tubal disease, rather than premature excision of the affected tube (Polk).

A most eloquent tribute to the success of conservatism in dealing with the appendages is the record of thirty-two childbirths in twenty-nine women whose appendages were conserved; surely an object lesson which the thoughtful surgeon should not soon forget.

And thus it will be seen that all along the lines in surgery a conservative trend is apparent. We are now sifting the gems from the sands we have shoveled in past years, and separating the true from the false doctrines of modern surgery. The most precious metals are in mining found off mixed with many that are dross; and no true progress is ever made in life without mistakes along the way. The day of extreme radicalism is passing fast; but, had it never dawned, the sunlight of to-day's conservatism would never have shown through Ignorance's sable cloud.

## PNEUMOTHERAPY IN PULMONARY HÆMORRHAGE.\*

By CHARLES E. QUIMBY, A. M., M. D.

It is now nearly twelve years since the pneumatic cabinet was presented to the medical profession as a means of applying antiseptics to the pulmonary surfaces. It is over ten years since I began its use in the treatment of thoracic diseases. Very early in those ten years I became convinced that its special value lay in its power to modify both the pulmonic and systemic circulations.

The experience of later years has only served to strengthen that conviction and to crystallize it into abso-

\* Read before the Society of Alumni of Bellevue Hospital, April 1, 1896.

lute certainty, that for some purposes the cabinet is incomparably superior to any other measure at present at our command. One of these purposes is the arrest and prevention of pulmonary hæmorrhage. To support such a claim it is necessary (1) to demonstrate that the cabinet may be so applied as to develop conditions that favor the arrest of hæmorrhage, and to remove or minimize a part or all the causes that induce hæmorrhage; and (2) to present the clinical evidence that its influence in these directions is sufficient to justify the statements made in its behalf. Infarctions, pulmonary apoplexy, and the immediately fatal hæmorrhages from large vessels are excluded for the present, and the discussion limited to the hæmorrhages commonly associated with phthisis. Hæmorrhage of cardiac origin is more properly considered in connection with the pneumatic treatment of valvular lesions. I consider first the arrest of hæmorrhage.

With the flow of blood once established, it is evident that it can be permanently arrested here as elsewhere only by the formation of a clot, and that the formation of such a clot is determined by one or more of three causes: (a) Modification of the blood elements; (b) reduction of vascular tension with slowing of circulation, and (c) compression of the bleeding vessels.

Upon the first of these the cabinet has no direct influence. For effecting the other two it is, *facile princeps*, our most powerful measure. To accomplish this we employ continuous respiration under negative differentiation with rarefactions of from a half to three quarters of an inch of mercury. This is called differential respiration. In such conditions, a patient respires with the pulmonary circulation under existing barometric pressure, while the entire cutaneous expansion is relieved of from a quarter to half a pound pressure to the square inch.

These figures at first seem small, but when it is remembered that the effect is directly and primarily upon the capillaries, their significance is more apparent. The result is capillary dilatation and lowering of the systemic vascular tension, by which the venous system is filled to distention, while the pulmonary vessels suffer corresponding depletion and a slowing of their circulation under a lowered tension. These statements, based on the physics of the cabinet and the circulation, do not lack clinical proof.

The effect is so decided that few persons, even with perfectly healthy lungs, can endure to breathe under a rarefaction of half an inch of mercury for more than three or four minutes. For while the amount of air inhaled with each inspiration is largely in excess of the normal, the pulmonary circulation is so retarded that there is marked deficiency of oxygenation. The external evidences of this cupping effect are equally prominent. No one who has seen the flushing skin and swelling veins, with often a more or less abundant perspiration, that develop under this motion can ever question the influence

of even small differential pressures upon the circulation. Indeed, simple appreciation of the fact that the action is that of one huge cup forbids denial of its influence upon the circulation to any one who trusts in dry cups over a small portion of the chest to relieve inflammatory hyperæmia or to stimulate the absorption of mechanical transudations.

It should be understood that when the patient is compelled by lack of breath to drop the breathing tube, the rarefaction within the cabinet is at once removed by allowing a free influx of air, so that the pulmonary circulation may still have the support of barometric pressure. While it is thus impossible to deny the influence of pneumatic differentiation in retarding pulmonary circulation and diminishing its tension, one can not offer clinical but only physical proof that there is at the same time a compression of the pulmonary vessels. It is certain, however, that the ratio between vascular tension and atmospheric pressure in the lung is changed in favor of the latter, and that there is, therefore, relative compression of the vessels as compared with conditions of common respiration, a compression which must diminish the calibre of those vessels. And when we recall that the vast majority of pulmonary hæmorrhages are from superficial capillaries or minute veins in which tension is normally very low, it does not seem difficult to believe that such tensions may be reduced during differential respiration to the point where atmospheric pressure may cause occlusion of the vessel. Should the differentiation obtained by the cabinet alone not suffice, the use of compressed air for inhalation in connection with the cabinet must certainly cause compression of superficial bleeding vessels.

With hæmorrhage thus arrested, we have to consider secondly the prevention of its recurrence. For our present purposes the causes of pulmonary hæmorrhage may be condensed into two: Increased vascular tension and diminished nutrition of the vascular walls, resulting in weakening and diminished resistance. To fully appreciate the beauties of the cabinet action in diminishing tension and increasing nutrition, it is necessary to bear in mind that vascular tension serves solely the purpose of moving the blood through the vessels, for, if I mistake not, it is now generally admitted that nutritive interchange depends upon cellular action and not upon mechanical transudation. It is certainly well recognized that the vessels of an organ in functional activity are dilated, while vascular contraction marks those parts in which the circulation is relatively diminished. Tissue nutrition may therefore take place under lowered tension, provided the flow of blood is maintained. The evident indications in the condition under consideration then are, to hasten pulmonary circulation as a means of augmenting tissue nutrition, without increased and, if possible, with decreased vascular tension. It is precisely this which is accomplished by the cabinet, by the motion termed forced inspiration.

When, after a few days', possibly a week's, treatment by differential respiration alone, we feel sure that the protective cloths are firmly established, that motion is replaced by forced inspiration. At first, the rarefaction employed is but little more than has been used for differential respiration. But day by day it is increased until the maximum that is deemed advisable for the case in hand is reached. This may require anywhere from two to ten days. What now is the physics of this motion? During inspiration the condition is that just described for differential respiration, and the action that of a general cutaneous cupping. With the higher rarefaction the effect is greater, and at two inches of mercury, if the breath is held for two or three seconds after the lungs have reached full inflation, the capillary hyperæmia of the skin and the venous distention become very evident.

At this point the breathing tube is dropped from the patient's mouth, as the controlling valve is closed, and the pulmonary pressure instantly drops to that upon the skin. The resulting effect upon pulmonary circulation is a point in the cabinet physics which is seldom appreciated. Every one recognizes that the influence of extreme diminution of atmospheric pressure, such as is found at high elevations, is most marked in the lung, where the circulation is largely capillary—i. e., in thin-walled vessels, which also find little support from the associated tissues. Yet we are apt to forget, notwithstanding the frequency with which pulmonary and bronchial disturbances are associated with a falling barometer, that every decrease of atmospheric pressure, however slight, will have proportionately the same relatively greater influence upon the pulmonary circulation. With the case in hand the sudden change in pulmonic pressure may be as much as a pound to the square inch, and takes place when the pulmonic circulation is depleted, while the systemic veins are distended.

As a result there is a rapid filling of the lung, but under low tension, to the point of a moderate hyperæmia. The superficial evidence that such a change occurs is found in the instantaneous collapse of the superficial veins as soon as the patient drops his tube. Within the time required for a single deep respiration from the rarefied air of the cabinet circulatory equilibrium becomes established, and the patient takes the tube for another inspiration. As this begins, pulmonary pressure is again changed by a restoration of barometric pressure. The ratio between pulmonic and cutaneous pressure is now again in favor of the latter instead of the former. The cutaneous vessels are again distended and the pulmonic depleted by a hastened onward flow of blood. The cycle is thus completed, and by repetition both circulations are hastened and tissue nutrition is augmented, and yet at no time is there any increase of vascular tension. On the contrary, in both circulations, the force which increases the blood current is of the form known as suction.

Time forbids any consideration of the effects of these circulatory changes and varying atmospheric pressures upon inflammatory exudates, mechanical transudations, and accumulated secretions, although they are of almost equal importance in effecting tissue nutrition.

In reply the criticism which has been so often made, that, admitting all which is claimed for the action of the cabinet from a physical standpoint, it is impossible to believe that its application for fifteen or twenty minutes a day can be productive of any valuable amount of nutritive change, I can only offer the clinical results.

I have selected from my patients of the last five years fifty cases, taking those which have been longest under observation as being the ones most liable to present recurrent hæmorrhages. Several have been watched through the entire five years and none less than a year.

Before referring to these cases in detail, I wish to say that in ten years, during which time, save through about two months of the summer, I have never had fewer than ten patients, and often as many as twenty-five to thirty, under observation, I have seen but two cases of hæmorrhage which I could not arrest.

Of these, one was a case of acute diffuse infiltration of both lungs, developed from a localized tuberculosis of one apex. Even in this case the hæmorrhages were made less frequent. The other was a case of most acute phthisis involving a large portion of the right lung. The hæmorrhages had been most severe and continuous at the time of the first treatment and continued without change during the ten days the patient lived. I have had occasion to put but two patients in the cabinet when the blood was coming in large quantities. One of these was the one whose case has just been related, the other will be given in detail. A large number, however—just what proportion I can not say—had been expectorating pure blood within six to twenty-four hours of the time of receiving their first treatment.

Of the fifty selected patients, seventy-eight per cent. had had hæmorrhages or bloody expectoration at some time previous to treatment. Forty-four per cent. at least had had very decided hæmorrhages. Of these fifty, and I might add of all my patients, but three have had a distinct hæmorrhage during their course of treatment.

One was a case of well-developed phthisis which was treated with tuberculin, and which was later arrested by cabinet treatment. A second was a case of localized infiltration in a patient who, from past experience, knew that city air was rank poison to him, but who insisted upon having the treatment because a friend had been benefited.

The third was a case in the last stages, with extensive laryngeal ulceration, that had been sent home from the Adirondack sanitarium, and which was treated solely to please the patient and his parents. These cases are not included in the fifty.

The nine out of fifty patients who expectorated blood

while under observation I divide into two classes: First, those who had a distinct hæmorrhage—i. e., expectorated pure blood; and second, those who had bloody expectoration—i. e., mucus streaked with blood. Of the former class there are but two cases (four per cent.), both of which will be given in detail. Of the last there are seven cases (fourteen per cent.).

The following are the two cases of the first class:

*CASE I. Hæmorrhage while under Observation but not with Treatment.*—Mr. L., a young man of twenty-eight years, came to me the last of February, 1891, suffering from moderate but persistent hæmoptysis. His attention was first attracted to the lung by a similar attack in the fall of 1889. He was then sent to Denver by the late Dr. Loomis. A year there seemed to have given him a complete cure of his disease, and he returned to New York in the fall of 1890. Just four months after reaching New York he was attacked with the hæmorrhage, for which, after it had continued intermittently for two weeks, he consulted me. At that time he had moderate localized consolidation at each apex. He was spitting clear blood in considerable amount the day he came to my office, and was at once placed in the cabinet and given appropriate treatment, which was repeated daily. For two or three days he expectorated dark clots and bloody mucus, but no bright blood after the first treatment; then only the stained sputum, and before the end of the week all traces of blood had disappeared.

He continued daily treatments for ten weeks, then three times a week for about six weeks, when he was told that his tuberculous processes as well as the hæmorrhages were arrested, but he was warned that the same climatic conditions of New York which had originally developed his trouble would again excite it to activity unless he took measures to guard against it. He was therefore advised to return for occasional treatment. This he failed to do. Nevertheless, this patient, who had gained only four months' immunity from a climatic cure obtained by a year's residence in Denver, enjoyed a year and four months of full health as the result of four months' treatment by the cabinet. Then his old enemy returned, and the last day of the Columbian celebration of 1892 he walked into my office with a profuse hæmorrhage. Again the cabinet; again almost immediate relief of the hæmorrhage; a month of pretty regular treatment; two months of twelve or thirteen treatments a month; since then, perhaps, twenty treatments in all. Results: no sign of blood since 1892, no cough or trouble of any kind. For the last three months patient has been working as an "overlay cutter," and as a prophylactic has begun occasional treatment.

*CASE II. Hæmorrhage during Observation but not during Treatment.*—Mr. D., a man about thirty-five years old, had his first hæmorrhage seven years ago. He recovered perfectly, and for two years was devoted to athletic exercises. Then the hæmorrhage was repeated with much the same result, but the third one came after a shorter period, and then they became more frequent. During these years he spent a part of each summer in the Adirondacks.

Finally, in July, 1894, after a series of hæmorrhages, he again started for the mountains, but in such a condition that his physician (as stated to me personally) did not expect him to live to reach his destination. For the next five months he had a series of hæmorrhages com-

ing twice and three times a week. During this time he was not able once to lie flat down in bed, nor did he once go to bed without a hypodermic loaded with morphine, which he used upon the slightest indication of cough. That he was near Saranac at this time is sufficient proof that he had the most approved treatment. Early in November he returned to his home and enjoyed about ten days' respite. Then began a week during which (according to his statement) he had two and three hæmorrhages a day. Late in the afternoon of November 16th his wife left him bleeding and came to New York for advice. She was urged to bring him to the city at once. In the forenoon of the 17th he reached my office much exhausted. He was not bleeding then, but had been within twelve hours. All the evidences of anæmia were marked. His dyspnoea was extreme, although under the influence of morphine as he had been for months. He was at once placed in the cabinet, and received daily treatments until January 1st.

In January he received only ten; in February, eight; and in March fifteen treatments. Results: up to this time no sign of blood, although at the end of five days he was deprived of his codeine, which he was taking regularly and freely. At the end of the first week he went to bed without his hypodermic and slept prone. Upon ceasing the codeine he began to cough and expectorate, much to his horror, as for over six months a hæmorrhage had invariably followed any severe coughing. At the end of two weeks he returned to his home in Orange, coming in each day for treatment, and before the end of a month he resumed his business down town, which he has continued ever since. The last of March, 1895, he went South, and later West, and did not return for further treatment until the 16th of July, when, on account of a very small hæmorrhage, he came down from the Adirondacks, where he had been for a month. Since then he has received treatment very irregularly, yet this patient, who had been having recurrent hæmorrhages for seven years, and almost continuous ones for six months, was not only relieved immediately, but, with that one slight exception, has been entirely free from all bleeding for over twenty months, although living under just the conditions which previously had caused them.

A single brief case for the second class: Mr. B., thirty-three years of age. During two years he had eight or ten moderate hæmorrhages—"not over one or two cupfuls," as he expressed it. Began treatment January 31, 1895, ten days after last hæmorrhage. Received eight treatments each in February, March, and April. In May, four; June, two; July, four. None again until October. During this time, while in the Adirondacks, he had one day two or three mouthfuls of blood. With this exception, no sign of blood in eighteen months, although, since October, he has had less than four treatments a month. This case fairly illustrates the seven cases of the second class.

It is only fair that it should be remembered that all the cases were treated under the disadvantages of New York climate, and that a majority continued their usual vocations. In conclusion, I believe that both the physics and clinical facts justify the statement that the pneumatic cabinet is not only unequalled as a measure for the treatment of pulmonary hæmorrhage, but is essentially a specific and practically certain in its action.

## TORTICOLLIS

DUE TO ADENOID VEGETATIONS AND  
CHRONIC HYPERTROPHY OF THE TONSILS.\*

By ARTHUR J. GILLETTE, M.D.,

ST. PAUL, MINN.

ALL meet with cases of torticollis of an acute nature due to inflamed glands, rheumatism, traumatism, nerve irritation, myositis, sprains, abscesses, hamatoma, etc., which of themselves soon disappear or respond quite readily upon the relief of the local conditions.

The cases, however, which I report here belong, I believe, to that class which is known as congenital or idiopathic wryneck, save one that is given simply to show how readily this deformity was cured by the removal of the adenoid vegetations in the retronasal space, and also demonstrates how, if long continued, the tonic spasm of the muscles would naturally cause a structural change in the contracted muscle, which would cause a contracture.

We know the changes made in the ribs and sternum, known as pigeon breast, often due to adenoid vegetations and hypertrophied tonsils and the typical facial changes due to this same disease.

My attention was first called to adenoids and enlarged tonsils as a factor in these cases some two years ago, when a case was referred to me with congenital wryneck. I was unable to find any other cause. The history is as follows:

A boy, aged seven years, well nourished, bright, and active; a remarkably good family history; right sterno-cleido-mastoid muscle so much contracted that the ear was within an inch of the shoulder; marked asymmetry of the face and head. The mother stated that as soon as she began to dress the child she noticed that "its head was crooked"—that is, within ten days after its birth—and that she could not straighten it. It was not, however, so marked that a stranger would notice. She observed that the cord (sterno-mastoid) showed much plainer on one side than on the other. The accoucheur stated to me, upon inquiry, that it was a normal labor aside from the traction with forceps, and that there was no injury to the neck or abrasion of the skin. The child seemed to have no pain and was not fretful in any way that would suggest any inflammatory irritation. The deformity gradually increased until it was very marked. I noticed that the child was a "mouth breather" and that his tonsils were much enlarged. I questioned her as to his breathing, and she stated that even in infancy he had always made a great noise in breathing in his sleep, and when awake never seemed able to breathe through his nose. As I could find no other cause for his condition I thought this might account for it, and referred him to a laryngologist, and he discovered not only the abnormal hypertrophy of the tonsils but a complete nasal stenosis, which he relieved and amputated the tonsils. When the boy returned to me there was a marked improvement in his facial expression as well as in his sleep. The mother remarked how much

better he seemed to be in every respect. I then etherized him and divided the sterno-cleido-mastoid, the head was easily brought into a normal position, and rotation was perfect. As a means of holding the head in a corrected position I employed the ordinary Sayre's jury mast, attached to a leather corset; this he wore for several months. Within six months the face was as nearly symmetrical as is usual. He is now perfectly cured, and there is no tendency and never has been to the return of the deformity.

My next case was that of a baby sixteen months old. The mother noticed, when he first tried to sit up, that he did not hold his head quite straight, and when he was old enough to be attracted by noise that he did not seem able to turn his head in one direction as well as in the other. She had noticed, a few weeks before bringing him to me, that when suffering from a slight cold he seemed to hold his head more crooked than at other times. The family history was good, the birth normal, the child was bright, and there was no evidence whatever of any paralytic trouble. The left sterno-cleido-mastoid was prominent and held rigid by tonic spasm; asymmetry of face and head and slight pigeon breast. This boy was also examined; the tonsils were not much hypertrophied, but the vault of the pharynx was filled with adenoid growths. These were removed. For a day or two the child seemed to hold its head in a more abnormal position than usual, but two weeks after, when he visited me, I felt sure I noticed an improvement both in the position of the head and the symmetry of the face.

I have no doubt that in this case it will be necessary for me to divide the contracted muscle. I say muscle, for I am unable to find any other than the sterno-cleido-mastoid involved.

My third case of this nature is not of the congenital variety. The child had been under my care in infancy and early childhood for rickets, from which it made a perfect recovery. I did not see the child again until it was three years old, and was then referred to me from the Medical Department of the Free Dispensary as a case of wryneck. The mother stated that some six weeks previous the child was suffering from a cold. A physician was called, and hot applications were made to the contracted side of the neck, and medicines administered internally. In fact, several physicians were called, but the child did not improve. I found no fever or constitutional symptom of any kind: there was no vertebral trouble, adenitis, or anything to cause the contraction of the sterno-cleido-mastoid muscle. I referred it to the Nose and Throat Department. There was, as in the other cases, the same condition of the vault of the pharynx—filled with adenoid vegetations. This was removed, and the child was referred back to me in two or three days entirely cured of the deformity.

In reading the literature upon wryneck I notice that in a large number of cases similar to the latter the patients have derived great benefit—in fact, many of them have been cured—by the use of gelsemium, and I wonder if its efficacy is not due as much to its effect on this inflamed tissue, controlling the inflammatory exacerbation, as to its antispasmodic action.

There are several practical points upon which I was

\* Read before the American Orthopedic Association, May, 1896.

unable to get the desired information from books. I wrote to Dr. J. E. Schadle, Instructor in Clinical Laryngology of the State University of Minnesota, who had operated in the cases reported, and the following is his reply:

ST. PAUL, MINN., May 12, 1896.

DR. GILLETTE: In your communication of to-day the following questions are asked:

1. How early in life do adenoid vegetations at the vault of the pharynx appear?

2. What conditions were present in the three wryneck cases on which you operated for adenoids?

In reply to these questions, I will briefly say that heredity undoubtedly forms an important factor in the production of hypertrophied lymphoid tissue, and that in the majority of instances where the retronasal space is involved in the morbid process the condition is congenital. The cases referred to in your second question were well-marked examples of the disease.

McC., a boy, aged seven years, had chronic enlargement of both the faucial and the pharyngeal tonsils. Complete nasal stenosis existed, and the patient's facial expression as well as his general appearance indicated the evil consequences of obstructed respiration. Complete removal of the obstruction restored nose breathing and produced a marked improvement in general health. Regarding the other two patients nothing except adenoid growths were found. The tonsils were not affected. In operating I employed the digital method on both.

The dispensary patient made a rapid recovery. Two days after the post-nasal operation the wryneck had entirely disappeared.

## Therapeutical Notes.

**Injections of Serum in Cholera Infantum.**—The following abstract from an article on this subject by Dr. Reinach, which was published in the *Münchener medizinische Wochenschrift* for 1896, No. 18, appeared in the *Gazette hebdomadaire de médecine et de chirurgie* for June 28th: In fifteen cases of cholera infantum the author employed subcutaneous injections of cow's serum in doses of from ten to twenty cubic centimetres. Four of the patients died; two had a concomitant broncho-pneumonia, and two a follicular gastro-enteritis of long standing. The effect of the injections manifested itself ordinarily in from six to eight hours after the administration of the serum, and from that time the temperature gradually rose, the extremities became warm, the cyanosis gave place to a rosy tint of the skin, and the diarrhoea was arrested. This condition generally continued on the following day, and recovery usually occurred after one injection only. In some cases, however, a second injection was necessary in order to maintain the good results which were obtained by the first one. Besides these injections, rice water was given. The author states that, from a nutritive point of view, twenty cubic centimetres of assimilable serum are equivalent to five ounces of cow's milk, or to an ounce and a half of the mother's milk.

**The Treatment of Pruritus of the Vulva.**—In the *Berliner klinische Wochenschrift* for 1896, No. 18, there is an article by Dr. Ruge, an abstract of which is pub-

lished in the *Gazette hebdomadaire de médecine et de chirurgie* for June 28th. According to the author, says the writer, pruritus of the vulva is not of nervous origin; at least, he has never met with that form; it is symptomatic of a lesion of the vulva, of the vagina, or of the neck of the uterus which gives rise to an abundant discharge. The treatment, consequently, he says, should be directed to the primary lesion. Local treatment is also important, and includes the disinfection of the genital region. This disinfection is done with corrosive sublimate and should be practised by the physician himself in order to be perfectly successful. Every three or four days the vagina and the vulva should be washed and rubbed carefully with a solution of the sublimate and afterward anointed with an ointment containing carbolic acid. The author states that he does not recall any case in which this treatment failed when the physician himself practised it.

**Carbolic Acid in the Treatment of Tetanus.**—Dr. Baccelli (*Polichinico*, November 15, 1895; *Centralblatt für innere Medizin*, July 4, 1896) says that for years he has made use of subcutaneous injections of from fifteen to thirty one-hundredths of a grain of carbolic acid in the treatment of neuralgia, whether acute or chronic, with great success. He reports about six hundred cases, among them some rebellious ones of sciatica, in which the remedy proved effectual. These results led him to try it in tetanus. In that disease he injects it every hour or every two hours into the region of the rigid muscles, keeping watch for symptoms of carbolic-acid poisoning, and has found that tetanic patients have a decidedly heightened tolerance of the remedy; as much as three grains in the course of a day is well borne in many cases. Both Italian and other physicians have witnessed the efficacy of this method of treatment in numerous instances. Babes, who has tested it experimentally and cured tetanized dogs, pigeons, and rats with it, ranks it as on a par with the serum treatment.

**Picric Acid in the Treatment of Itching of the Scrotum.**—The *Revue internationale de médecine et de chirurgie* for July 10th ascribes these formulæ to P. Brocq:

- (1.) R Picric acid..... 4½ grains;  
Vaseline. } of each..... 225 "  
Lanolin. }  
M. S.: For external use.
- (2.) R Picric acid..... 15 grains;  
Vaseline. } of each..... 225 "  
Lanolin. }  
M. S.: For external use.

**Phosphorus in the Treatment of Rickets.**—In an article by Dr. A. B. Marfan, in the July number of the *Revue des maladies de l'enfance*, the following formula is given:

- R Phosphorus..... 0.15 grain;  
Cod-liver oil..... 1,500 grains;  
Saccharin..... 75 "  
Essence of lemon..... 2 drops.  
M. A small teaspoonful may be taken daily.

**A Mixture for the Vomiting of Perityphlitis.**—The following prescription is attributed by the *Gazette hebdomadaire de médecine et de chirurgie* to Pick:

- R Menthol..... 8 grains;  
Cognac..... 600 "  
Tincture of opium..... 150 "  
M. From ten to twenty drops are to be taken several times during the day, in a little sweetened water.

D. APPLETON & Co.Edited by  
FRANK P. FOSTER, M.D.

NEW YORK, SATURDAY, AUGUST 1, 1896.

## THE OFFENSE OF SUBSTITUTION BY APOTHECARIES.

In this issue of the *Journal* we reprint an article that appeared in the *Pharmaceutical Era* for July 24 giving a letter distributed, we presume, among physicians by a well-known and highly esteemed firm of pharmaceutical manufacturers, Messrs. Fairchild Brothers & Foster, in which they call attention to the extent to which some apothecaries persist in dispensing something different from what is ordered by the physician. There is no excuse for the substitution of one preparation for another without the prescriber's consent. We do not think it is always fraudulent in design, but it always carries with it the possibility of fraud. The practice is far too common, and it will not do for the pharmaceutical profession to pass it over in any such words as have been attributed to a prominent speaker at a recent meeting of the American Pharmaceutical Association to the effect that he would have had something to say about substitution but for the fact that he knew that no pharmacist worthy of the name was guilty of it. If pharmacists are doing this thing to a considerable extent, and it seems undeniable that they are, what does it matter to the physician or to the patient whether or not they are "worthy of the name"?

The profession of pharmacy can not alone perhaps crush out the practice, but its influence ought to be exerted to the utmost to that end, and doubtless will be. An editorial article on the subject in the same number of the *Era* ought to go far toward leading the pharmacists to vigorous action. Our contemporary asks where the profession of pharmacy is drifting to if it has got to that point that a physician can not depend upon a druggist filling his prescriptions with what is ordered. Such a practice, if continued, says the *Era*, will work untold injury to the credit and standing of the entire pharmaceutical profession. Physicians are constantly saying that one of the principal reasons why they handle their own medicines is that they are then sure of what they are administering. Any such wholesale accusation against the integrity of druggists the *Era* regards as unjust and untrue, and adds, most undoubtedly with entire truthfulness, that there are thou-

sands of conscientious, upright, honorable pharmacists who would no more think of substituting in a prescription than they would of trying to pass a counterfeit bill. It is unfortunate, it adds, that reflection must be cast upon these honest druggists by the acts of their unscrupulous brothers, but all of this hue and cry on the part of manufacturers about substituting can not be ignored. Where there is so much smoke there must be some fire.

The *Era* closes its article as follows: "Every honest druggist owes it to himself and his profession to speak plainly on this subject. He should adopt the most strict rules for his own establishment; improve every opportunity to condemn the practice of substituting, and see that resolutions to this effect are passed by his local, State, and national associations. Each druggist should make it a point to give his physicians and his customers to understand that when a prescription comes into his establishment, it is filled with exactly what it calls for. There can be no middle ground, no compromise, no question on this point. Physicians who prescribe them and the manufacturers who make the goods must have no good cause for such complaints. The honor of the drug trade demands that this stigma be removed. It is not a question of dollars and cents alone, but professional honor is at stake, and we know that every honest pharmacist will join with us in the statement that the druggist who substitutes in his prescriptions is a disgrace to his profession."

But we can not expect influential members of the profession of pharmacy to suppress this evil single-handed; we of the medical profession have our duty to perform in the matter and more powerful weapons with which to carry on the conflict, but it is one that will call for all the resources of both professions, and both ought to be glad of the active co-operation of the manufacturing pharmacists.

## THE THYROID GLAND AND THE GENITAL APPARATUS IN WOMEN.

The *Centralblatt für innere Medizin* for July 11th contains an abstract of an article on this subject that ran through several numbers of the *Wiener medicinische Wochenschrift*, by Dr. J. Fischer. It is remarked by the writer of the abstract that the fact of there being some sort of relation between the thyroid gland and the generative apparatus in women has been known for centuries, but it is only in exceptional cases that the

relation of cause and effect is directly ascertainable, and in the great majority of instances nothing more than the *post hoc* is really made out. The author has been industrious and thorough in the collection of the data found in literature and has made a great number of investigations himself.

He arranges cases of related disturbances into two classes. The first class comprises those in which the primary trouble is in the reproductive organs. According to his observations, the occurrence of puberty does not give rise to swelling of the thyroid in more than about fifteen per cent. of the cases, but enlargement of one or both lobes was noticed at the time of menstruation in thirty-two out of fifty instances, and it occurs during pregnancy in a third of all the cases. The unfavorable influence of pregnancy on exophthalmic goitre, he remarks, has long been recognized. At the time of labor the gland increases in size to the extent of about half an inch, but the enlargement subsides during the lying-in period. A similar increase attends lactation and sexual excitement. At the time of the climacteric the gland sometimes degenerates, but sometimes an out-and-out goitre forms. It is not uncommon to observe an enlargement of the gland in connection with dysmenorrhœa, amenorrhœa, the formation of fibromyomata, etc., and myxœdema often comes on at the menopause.

The second class consists of cases in which the genital apparatus is affected by disease of the thyroid. Goitrous women are prone to suffer with menorrhagia and metrorrhagia. According to some authors, thyreoidectomy is apt to lead to atrophy of the genital organs. In three women who had had the gland removed, however, the author could not detect any disturbance of menstruation. Amenorrhœa is a common sequel of myxœdema, and in cretins the sexual power is generally reduced. Disturbances of menstruation have been said to be often the first symptom of exophthalmic goitre, but of the occurrence of amenorrhœa in connection with scleroderma, acromegaly, and adiposity there are few observations on record. The author himself has noted anomalies of menstruation in sixty per cent. of corpulent women.

## MINOR PARAGRAPHS.

### CELLULOID AS A MATERIAL FOR SPLINTS.

In the *Centralblatt für Chirurgie* for July 18th Professor Landerer and Dr. E. Kirsch mention the great drawbacks of plaster of Paris as a splint material—its

weight and its proneness to become foul by absorbing sweat, urine, etc. They say that in the Medico-mechanical Institute of Stuttgart celluloid has been found an excellent substitute free from these disadvantages. A wide-mouthed bottle is packed for about a quarter of its height with celluloid cut into small pieces and then filled with acetone. It is provided with an air-tight stopper to guard against evaporation. From time to time it is opened and the contents are stirred with a stick. The celluloid dissolves in course of time. A plaster cast of the diseased or injured part is covered with a moderately thick layer of felt or flannel, and the celluloid solution is rubbed into this covering with the hands, which are to be protected with leather gloves. This process should be repeated from four to six times. The advantages of the celluloid splints and corsets are their lightness, hardness, stability, elasticity, and cleanliness.

### THE ILLINOIS STATE BOARD OF HEALTH AND CHEAP-JOHN MEDICAL SCHOOLS.

LAST week we published a letter from a Chicago physician in which statements were made that, unless they can be contravened, show a woful degree of remissness on the part of the State board of health in the matter of recognizing medical schools that fall far short of deserving the board's recognition. On the other hand, we have received a pestilent little pamphlet entitled *Annual Announcement of the Illinois Health University* which is for the most part denunciatory of the board and of all persons who insist on any sort of regulation of the practice of medicine as constituting a tyrannical "medical monopoly ring." We infer that the Illinois diploma mills are not having things all their own way, but they ought not to be suffered to exist. Let the board be a little more vigilant, as it was in the times of the late Dr. Rauch.

### LEAD GOUT.

DR. H. LÜTHJE (*Zeitschrift für klinische Medizin*, xxix; *Centralblatt für innere Medizin*, July 18, 1896) writes of a form of gout dependent on chronic lead poisoning. He would limit the term to cases in which gouty manifestations are associated with those of chronic saturnism and are without any other ascertainable cause than the action of lead. It has to be diagnosed from acute articular rheumatism and from saturnine arthralgia; in the latter there are no inflammatory phenomena.

### ITEMS.

**Vigorous Action against Substituters.**—The *Pharmaceutical Era* for July 2d contains the following:

"Fairchild Bros. & Foster have recently adopted vigorous methods for dealing with those druggists who substitute other preparations when Fairchild's are ordered, as will be seen by the following letter:

\* opp.

"DEAR SIR: We beg to call your attention to the following statement of facts, which we believe will be of great interest to you as a practising physician, relying upon the pharmacist for dispensing the medicines which you prescribe.

"On a recent date a prescription of a . . . physician, ordering 'essence of pepsin, Fairchild's,' was sent to . . . drug store. The bottle dispensed upon this prescription was immediately sealed in the presence of a witness and

expressed to us. A copy of the prescription was asked for and obtained, which proved to be an accurate transcript of the prescription, bearing date and number corresponding to those upon the label of the bottle dispensed. Upon examination, the content of said bottle was found to be a fluid differing materially from Fairchild's essence of pepsin, so as to be obviously recognizable as a plain violation of the physician's prescription.

"Another written order for Fairchild's essence of pepsin was sent to Druggist . . . . Upon examination, this proved likewise to have been filled with a different and inferior fluid.

"Subsequently, the same day, a messenger was sent to . . . . and asked verbally for four ounces of Fairchild's essence of pepsin. He received a wrapped vial, for which he paid fifty cents. This bottle was found without label, and the messenger returned and asked to have the bottle labeled. The druggist then simply labeled it 'essence of pepsin.' Thereupon, the messenger requested the druggist to put 'all the name on the bottle.' The druggist told the messenger that he 'would not dare to put Fairchild's name on the label, although it was all the same.' The druggist finally admitted to the messenger that he was 'out of Fairchild's essence,' and then returned the fifty cents.

"There is one significant fact that should also be mentioned: the price charged in these cases (as in every instance coming to our knowledge) is the same as the patient would be charged by pharmacists who dispense the genuine medicine ordered. Comment is unnecessary.

"In defense of our own rights, and in order that you may take such means as you deem best to protect yourself and your patients, we advise you of these facts. We further respectfully request that in prescribing Fairchild's essence of pepsin you will kindly send the prescription to pharmacists, of whom there are many, who will faithfully respect their legal and professional obligations to physicians and to the public.

"These prescriptions, sealed and certified, are in our possession, and we stand ready to still further substantiate these statements. Very respectfully yours,

"[Signed.] FAIRCHILD BROS. & FOSTER."

"In explanation of their action, a member of the firm states as follows:

"We have suffered very great injury by reason of this substitution, especially in the case of our essence of pepsin. Endurance has now ceased to be a virtue, and we shall take aggressive steps to protect our interests. We propose to let the physicians know which druggists do not dispense our preparations when they are specifically ordered. We shall follow this policy as being, in our judgment and upon legal advice, a direct and simple method of going right to the core of the evil.

"We have long hesitated to take this aggressive action, for reasons which you will readily appreciate. The direct injury by loss of business, besides the indirect and insidious injury to our reputation and the reputation of our goods, compels us to protect our interests. We had hoped that this most despicable abuse of confidence and fraud would cure themselves by virtue of the condemnation and protest they would arouse among druggists. We have noticed, however, that many honorable pharmacists, while condemning such action without reserve, refuse to believe that such substitution exists to any extent among the druggists. For instance, in the last report of the proceedings of the American Pharmaceutical Association, a prominent speaker is quoted as follows: "I would have wished to say something about substitution, but I know that no pharmacist worthy of the name is guilty of this fault, by which he would lose his good reputation, and by which public confidence which he has until now enjoyed would be destroyed. I will not say anything about it." Others confuse the subject by discussing a whole lot of matter utterly foreign to the plain, clear fact that there are druggists who, when a doctor orders a certain preparation, dispense something else. This is the only substitution of which anybody complains.

"The principal product of ours for which substitutes are most sold is our essence of pepsin. This preparation we originated sixteen years ago, and we may fairly say that it is to-day one of the best known and most used of pharm-

aceutical products. Time and time again we have detected druggists substituting inferior preparations for it. The attitude taken by these druggists showed very well that they fully realized what they were doing. When first charged with substitution, the druggist becomes very indignant and is apt to state that "he does not do that sort of thing," "always puts up what the doctor orders," etc. Upon being confronted with the proofs, he then throws himself upon our generosity, and begs of us not to expose him, promising not to do so again. Here is a recent illustration. A doctor wrote that he had stopped using our preparations because, in endeavoring to prepare some milk with Fairchild's essence of pepsin, he spoiled two gallons of it in a hospital, was greatly annoyed, and lost confidence in our products. Upon investigation we proved to the doctor the repeated substitution of another and inferior preparation supplied upon the hospital requisition, which plainly called for Fairchild's essence of pepsin.

"Another instance. One of the most prominent doctors in New York wrote a prescription which called for "Fairchild's phenolated essence of pepsin." The druggist made some mixture with creosote, and the patient's complaint of ill effects caused the doctor to investigate, when he discovered that liberties had been taken with his prescription. Another case was when a physician ordered for an infant some food to be prepared by a method which we suggested by the use of Fairchild's essence of pepsin, and after repeated failures to carry out the physician's instructions, the party told the doctor he believed there was some mistake, and he was requested to see the druggist. The druggist was indignant, but refused to say what he had used, simply stating that he had dispensed just what the doctor ordered. A sample of the prescription was submitted to us, and it took us but a few moments to discover the substitution and to convince the party that Fairchild's essence of pepsin would do just exactly what the physician wished to accomplish with it. The gentleman thereupon called upon the druggist, who then confessed and begged not to be exposed.

"We have spent considerable time in following up just such cases as these, and we have now determined to take what promises to be a more effective line of action to protect our interests. We do not claim any exclusive right to make essence of pepsin. We do claim, however, the exclusive right to make Fairchild's essence of pepsin. We have expended large sums of money to develop and introduce our preparations, and when a physician prescribes Fairchild's essence, in justice to the physician, to the patient, to the reputation of the druggist, as well as ourselves, we expect that Fairchild's essence shall be used.

"There is another and most important factor in this substitution business. We refer to that class of manufacturers who devote their energies to producing imitations of standard products. These green goods of pharmacy are the most contemptible of all imitations. They are urged as substitutes upon the druggist as "just as good" and "much cheaper." The agents of these houses will go so far as to call the druggist's attention to the fact that he can substitute his product when such a one is ordered, and make a much larger profit. We try to work on original lines and produce articles of intrinsic value. Our principle is to see how good we can make our products and not how cheap.

"We regret that we are forced to take these active steps for the protection of our interests. We sympathize with the druggist and know something of the many difficulties with which he has to contend. We have always tried to be fair and square in our dealings with the trade. We ask only for that to which we are entitled, and every conscientious druggist will recognize the justice of our demands."

#### The Richmond Academy of Medicine and Surgery.—

At the last regular meeting, on Tuesday, the 28th inst., the order for the evening was a paper entitled Strangulated Hernia, by Dr. W. H. Harrison.

#### The Kentucky School of Medicine.—

At a meeting of the faculty, held on the 21st of July, the chairs occupied by Dr. W. H. Wathen and Dr. M. F. Coomes were declared vacant. As yet the successors to these gentlemen have not been appointed.

**Infectious Diseases in New York.**—We are indebted to the Sanitary Bureau of the Health Department for the following statement of cases and deaths reported during the two weeks ending July 28, 1896 :

DISEASES.	Week ending July 21		Week ending July 28.	
	Cases.	Deaths.	Cases.	Deaths.
Typhoid fever.....	25	4	17	7
Scarlet fever.....	39	3	44	3
Cerebro-spinal meningitis. . .	3	3	7	6
Measles.....	131	11	105	7
Diphtheria.....	191	20	192	23
Tuberculosis.....	172	95	139	105

**A Repudiation.**—We have been asked to publish the following, dated New York, July 25, 1896 :

"To the Medical Profession: We, the undersigned, having seen our names attached to a circular which is being distributed by one Dr. George W. Caldwell as an advertisement in soliciting business in a manner contrary to the established rules of the medical profession, desire to state that the letters given to Dr. Caldwell were letters of introduction to the members of the medical profession of California, where he said he was going to settle ; and that his publication of our letters in the manner shown in his circular is entirely unauthorized by us and is dishonorable in the extreme, and we do not indorse him in the manner stated in the published letters as the practitioner he claims to be.

[Signed]      "JOHN A. WYETH, M. D.,  
                   "THOMAS R. POOLEY, M. D.,  
                   "V. P. GIBNEY, M. D.,

WEDNESDAY, August 5th : Medical Society of the County of Richmond (Stapleton), N. Y. ; Bridgeport, Connecticut, Medical Association.

THURSDAY, August 6th : Society of Physicians of the Village of Canandaigua, N. Y. ; Cuyahoga, Ohio, County Medical Society.

### Births, Marriages, and Deaths.

#### Married.

BALDWIN—SISTRUNK. — In Tallassee, Alabama, on Wednesday, July 23d, Dr. Benjamin J. Baldwin, of Montgomery, Alabama, and Miss Katie Sistrunk.

#### Died.

BLANC.—In Asheville, North Carolina, on Saturday, July 25th, Dr. H. William Blanc, aged thirty-five years.

FESSENDEN.—In Salem, Massachusetts, on Thursday, July 23d, Dr. C. S. E. Fessenden, of the Marine-Hospital Service, in the sixty-eighth year of his age.

HURLBUT.—In Chicago, on Friday, July 24th, Dr. Vincent L. Hurlbut, in the sixty-seventh year of his age.

OTTERSON.—In Long Branch, on Friday, July 24th, Josephine C. Ottersson, wife of Dr. William C. Ottersson, of Brooklyn.

WHARTON.—In Port Gibson, Mississippi, on Thursday, July 23d, Dr. Richard G. Wharton, in the eighty-second year of his age.

WYMAN.—In Charleston, South Carolina, on Sunday, July 19th, Joseph Maybank, infant son of Dr. Joel W. Wyman, of Denmark, South Carolina.

### Letters to the Editor.

#### THE HYGIENE OF THE NOSE.

943 MADISON AVENUE, NEW YORK, July 27, 1896.

To the Editor of the *New York Medical Journal*:

SIR: In the number for July 18th of your valuable *Journal* Dr. Carl Seiler, of Philadelphia, publishes an article on The Prophylaxis of Nasal Catarrh. He arrives at the conclusions which I advocated about a year ago in my article on The *Ætiology of Post-nasal Catarrh* (*Jour. of the Am. Med. Assoc.*, November 9, 1895), in regard to overdressing, overheating, and too close confinement indoors. I dealt at length in the said article upon these *ætiological* factors and tried to prove that they were as injurious for children as for grown people. I am glad that Dr. Seiler apparently agrees with me in this respect,

and I am happy to see that physicians realize that we have done too much hothousing, not alone for ourselves, but for our children. (In reviewing my article Professor Moritz Schmidt, of Frankfurt on the Main, commensurates my ideas perfectly.)

But when my esteemed Philadelphia colleague further states that another important factor in preventing nasal catarrh is cleanliness of the nasal cavities, I differ with him entirely. He explains this sort of cleanliness in the following manner: "Let, therefore, a child, as early as possible in life, be taught to snuff up the nose a warm saline or alkaline solution, with or without the addition of antiseptics. . . . three or four times morning and evening. . . ."

After a long, sad experience the medical profession has learned the great value of asepsis. We have accepted it, have grown enthusiastic over it, and now live in the era of overasepsis. Imagine the idea of cleansing twice daily a perfectly healthy nose! In dentistry, Dr. Seiler says, for a long time this same principle of cleanliness has been insisted upon; why should not the rhinologist follow in their footsteps? If we argue in that manner, let me ask only, why, reasoning on the same lines, do we not pump out the stomach twice a day? We should surely find much undigested food. Why not wash out the healthy urethra and bladder daily? Why not evacuate the whole intestines by antiseptic solutions, etc., *ad infinitum*?

Will the doctor not give Nature a chance to do anything for us? There are few things so useless, to say the least, as the snuffing up of water into a healthy nose. If there is any secretion, if there are dried scabs, etc., these washings will rarely reach them, and if there are none, I do not see any necessity for troubling our children. On the other hand, direct injuries may follow this snuffing up. The water rarely gets into the accessory cavities. But let there be an obstruction and let anybody try to force it through, and it will happen, even if "intelligently" used, that we drive just the noxious elements of the introitus narium into the frontal or ethmoidal cells. I have seen such affections occur and others undoubtedly have seen them, too. That in acute coryza or similar affections the infection may still more easily be carried into the accessory cavities and cause acute empyema, will be readily understood by everybody. I can not, therefore, approve of this cleanliness, "whether a cold in the head is present or not." On the contrary, I can not warn the profession sufficiently against such unnecessary and harmful procedures.

I know of a physician in this city who daily washes or syringes out his children's healthy eyes, noses, throats, and ears!

Poor father; poorer children!

W. FRIEDENHAI, M. D.

#### DIPHTHERIA ANTITOXINE IN CHICAGO

285 LOOMIS STREET, CHICAGO, July 26, 1896.

To the Editor of the New York Medical Journal:

SIR: I beg to trouble you once more, by stigmatizing Medical Inspector Murdock's statement, that I refused to attend the boy that he attended, as a gross calumny. On the contrary, I urged the mother to allow me to continue, since his condition was so satisfactory, but she insisted on paying me two dollars for three visits, adding she would send for me. I reside only a block from her house. Had I been permitted to follow up the treatment

a little longer I unhesitatingly believe a premature and precipitate death would have been avoided.

It is no unusual occurrence for city stipendiaries of the antitoxine species to try to stifle comment on the degree of denouncing the taking of the widow's mite while apologetic of their own conduct.

Unbiased people will readily see that personalities are out of place in discussing this unfortunate case.

W. J. NOLAN, M. D.

#### EXTRAGENITAL CHANCRE.

CHICAGO, July 26, 1896.

To the Editor of the New York Medical Journal:

SIR: In my letter published in your *Journal* for June 6th, I reported six cases of extragenital chancre. In putting these cases on record, I thought I was doing my duty as a physician, believing they were of some statistical value. I did not intend to start a discussion, but, having reported them, I feel that it is my duty to reply to my critic.

Dr. Sharpe could not have read my report very carefully, or else he could not have made the criticism he did of Case I. The doctor will please observe that the case was under my care nearly *three years*. The induration, deep ulceration, and perforation did not occur at the same time, but followed each other in logical sequence—the deep ulceration and perforation being more than a year later than the induration, the perforation, of course, following the deep ulceration.

The same reply may be made as to Case II, except that the deep ulceration of the tonsils followed the induration at an earlier date.

In Case III the mucous patches occurred when the induration and enlargement of the cervical glands were disappearing.

In reference to Case IV, there is some ground for his criticism, as I neglected to state that the mucous patches and deep ulceration did not occur at the same time as the primary sore, but followed it in due order. Still, such was the inference, as all of the cases remained under my care some time—from four months to three years.

In Case V there is no evidence to show that the father had syphilis at the time of the child's conception, and it is an accepted law that the mother may have syphilis at the time of the birth of her child and yet the child escape infection. The douches were given simply as a safeguard and to keep the parturient canal as free as possible from syphilitic virus.

Why Case VI should be regarded as tertiary syphilis, I fail to understand. There was not the slightest evidence given in my report to support this supposition. On the contrary, there was an indurated lesion and there was enlargement of the nearest lymphatic glands on the lymphatic vessels that drained the surface on which the lesion occurred. (The lymphatic glands on other parts of the body were not enlarged.) A little later, mucous patches occurred in the patient's mouth and there were syphilitic headaches of the early second stage. The alopecia belonged to this stage. Her history was that of recent infection.

I have charge, as an instructor, of the largest throat clinic in Chicago. For five years I have been associated with this clinic. One of the phenomena that I have observed is the early appearance of mouth and throat symptoms after the observation, by the patient, of the initial lesion. Many of the patients that have come

under my care have suffered from deep ulceration of the tonsils within six months after they noticed the chancre. The same condition has held good in my private practice.

The throat clinic of which I speak has been very rich in syphilitic affections of the mouth and throat, and, if Dr. Sharp will visit my clinic, I shall be glad to demonstrate to him all stages of syphilitic affections of the throat, and I think I can convince him that deep ulceration of the tonsils often follows "hard chancre" at an early date. E. D. SMITH, Ph. C., M. D.

## Proceedings of Societies.

### AMERICAN ASSOCIATION OF GENITO-URINARY SURGEONS.

*Tenth Annual Meeting, held in Atlantic City, on Tuesday and Wednesday, June 2 and 3, 1896.*

The President, Dr. CLAUDIUS H. MASTIN, of Mobile, in the Chair.

*(Continued from page 151.)*

**Good Results following Urethral Resection.**—Dr. EUGENE FULLER, of New York, read a paper on this subject in which he stated that during the past year he had encountered two cases in which, owing to the extensive destruction of the urethral canal, he had at first expected to be obliged to establish an artificial route (either perineal or hypogastric) in order to insure a satisfactory and permanent outlet for the vesical contents. In both of these cases, however, by resorting to a very radical and extensive excision of the diseased urethral areas, he had been able to restore the normal urinating function and to leave the urethral canal apparently permanently of good calibre. In one of the cases the excised tissue had included the entire bulbous urethra, fully an inch of the penile urethra anterior to the bulb, and the anterior half inch of the membranous urethra. In the second case an inch and three quarters of the urethra had been removed. In this case the removed tissue included the bulbous urethra and the anterior portion of the membranous urethra. The first patient had been operated on about a year ago, and had been under observation ever since. Although the urethra was somewhat tortuous, it admitted freely an 18 American, and showed no special tendency to contract. In the second case, in which an operation had been done about ten months ago, the urethra admitted a No. 17 easily four months after the operation. Since that time, Dr. Fuller said, he had not had an opportunity to examine the patient personally, although he had heard from him that he was well and in no apparent need of surgical attention.

Dr. WHITE said that in one case of injury to the urethra which had come under his observation a considerable portion of the urethral wall had been missing. To fill this gap he had used a graft taken from the mucous membrane of the cheek. He was unable to say whether the graft had taken successfully or not. The patient had done well, however, and he was disposed to think that the transplantation had been a factor in bringing about the good result.

Dr. BRYSON expressed the opinion that in the cases reported by Dr. Fuller, particularly in the last one, the

time that had elapsed since the operation was too short to enable him to pronounce as to a permanent cure. In a case of that character, where an extensive resection was done, it would no doubt take a considerable period of time for the urinary canal to fill up.

Dr. CHISMORE expressed the view that the result of grafts within the urethra must be very uncertain.

**Movable Kidney: its Frequency; its Causal Relation to Certain Definite Symptoms; the Measure of Relief afforded by Nephrorrhaphy; a New Method of Applying Sutures in the Operation.**—Dr. FRANCIS S. WATSON, of Boston, thought that the importance of this subject was not sufficiently recognized in this country, in spite of a large mass of reliable data which was at the disposal of the profession. Movable kidney was regarded by many intelligent surgeons as a fad; by others as merely one manifestation of hysteria. Eminent pathologists continued to assert its great rarity, and mention of successful nephrorrhaphies was met with a shrug of the shoulder. The reasons for these doubts were probably as follows: The pathologist rarely found a movable kidney, because, in the first place, he rarely looked for it, and, in the second place, as Newman and Kendal Franks had pointed out, with the body in the dorsal decubitus the kidney naturally returned to its normal position and afterward was retained there by the solidification of the perinephritic fat after death.

As regarded the frequency of this condition, the speaker said, the following figures would prove of interest: Glénard, in 1893, reported that he had seen personally, between 1885 and 1893, 537 cases of movable kidney. Lindner, in 1888, asserted that one woman in every five was the subject of movable kidney. Edebohl, in 1893, said that he had found 90 cases in a series of 500 women who had been examined.

There were three symptoms as to the dependence of which upon movable kidney all authorities agreed. These were, in their order of frequency, pain in the loin or abdomen, disturbances of digestion of the character of atonic dyspepsia, and neurasthenic or hysterical symptoms. There was one other which was not often mentioned, but which, when present, was the most characteristic of all, namely, the sickening pain, accompanied by a sense of nausea and faintness, which occurred when the kidney was grasped between the hands or the fingers and thumb. It was just as characteristic, so far as one might judge from the description of patients, as the peculiar sensation was which men felt when the testicle was squeezed.

An important point in connection with this condition was the occurrence, in a considerable number of cases, of nephrydrosis, which, having been intermittent at first, sometimes became permanent, and the original gravity of it was occasionally added to by infection from the lower part of the urinary tract, which converted it into a nephropyosis, with destruction of the organ.

Dr. Watson briefly described his own method of suturing the kidney in the loin, which was as follows: After exposing the kidney by the usual lumbar incision, the fatty capsule which covered the posterior surface of the organ was excised and its cut edges were stitched a little distance from the margins of the wound. Two stout chromicized catgut sutures were then passed through two thirds of the entire length of the kidney, parallel to each other, and through the parenchyma of the organ, at a distance of half an inch from each other. They entered the kidney a little above its lower end and emerged a little below its upper end. Each end of the

suture was then passed through the edge of the muscular layer of the wound. Two other sutures were then passed in a horizontal direction through the substance of the kidney, one above and the other below the points of entrance and of issue of the two first sutures, and their ends were also passed through the muscular borders of the lumbar wound. The fibrous capsule was now split throughout nearly the entire extent of the posterior surface of the organ and reflected to a very slight extent toward either side, thus denuding the posterior border of the kidney to the breadth of the little finger. Instead of being tied in the ordinary way, that is to say, instead of one end being tied to the opposite end of the same suture, the end of one long suture was tied to the end of the other above, and the same was done below at the points where they passed parallel to each other through the muscular layer. The same was done with the cross sutures. In this way the danger of the stitches' tearing out was avoided. The kidney was drawn firmly into its place and maintained there by the sutures, thus being suspended as in a hammock.

Dr. CHISMORE said that Dr. Watson's paper had made such an impression on him that he should pay more attention to the subject of movable kidney in the future. He had noticed that certain of his colleagues found this condition with remarkable frequency. He had one undoubted case of floating kidney under his observation where the condition had been discovered by accident; but, as it had given rise to no marked symptoms, nothing had been done regarding it.

Dr. CABOT said he had operated in quite a number of cases of movable kidney which had given rise to symptoms in different degrees. In some cases the condition gave rise to nervous symptoms, in others to digestive disturbances, and in a third class to kidney colic. In the digestive, and still more in the latter class of cases, the most favorable results had been obtained by operative interference. In his later operations he had adopted the method originated by Guyon, which seemed to work very well.

Dr. WHITE said he was quite well satisfied that movable kidney existed far more frequently than many supposed; he was equally well satisfied that too many movable kidneys were being found and operated on to-day. He had never seen a death result from the operation, and he had never failed to observe at least temporary relief. The diagnosis usually rested between movable kidney and tumor of the gall bladder or some other intra-abdominal condition. One of the symptoms that aided in making a diagnosis of movable kidney was the variation in the quantity of urine passed due to torsion of the ureter. A history might be obtained of diminution in the amount passed, followed by a sudden increase and a relief of the symptoms. The procedure mentioned in most of the text-books, that of percussion over the loin, he regarded as being of very little importance. The speaker expressed the opinion that most of the symptoms which accompanied movable kidney were directly due to the condition itself, and were not of an hysterical character. The traction on the duodenum would account for the gastric phenomena, the obstruction to the outflow of urine would account for the renal symptoms, and the traction on the nerves would account for the nervous manifestations.

Dr. FULLER called attention to the fact that in cases where the capsule of the kidney was incised, a plastic lymph was thrown out which became firm and held the organ in place.

Dr. BRYSON said that an important reason for operating in these cases was the danger of suppurative lesions. In four cases in which he had opened the kidney for the purpose of draining a suppurative pelvis he had found the organ much lower down than it should have been. He agreed perfectly with Dr. Watson regarding the characteristic pain which was produced by compressing the kidney. As regarded the proper situation of the organ, he had obtained the best results by fixing it in a position where the ureter was neither stretched nor sufficiently relaxed to become kinked.

**Post-conceptional Syphilis.**—Dr. ABNER POST, of Boston, stated that, regarding the possibility of intra-uterine infection with syphilis, two opinions prevailed, one party affirming and another denying its existence, while a third party might be said to consist of those who admitted its possibility up to a certain period of pregnancy, and denied its possibility after a date which was set at various periods by different writers. Those who denied the possibility of such transmission rested their belief upon the well-known relationship between mother and foetus, which did not permit of the direct interchange of blood-corpuscles, and upon the probable fact that the contagion of syphilis was carried only by the blood-corpuscles and not by the serum, so that theoretically the transmission of the disease through the placenta was impossible.

The problem of infection of the foetus during intra-uterine life simplified itself into the question of whether pathogenic microbes might be transferred from the mother to the foetus or not. So far as analogy was concerned, different conclusions had been reached by different investigators. The latest opinion on this subject was to the effect that the microbes of pneumonia and typhoid fever and also the *Bacterium coli commune* passed the placenta and attacked the foetus *in utero*. We were justified in saying that the microbes of certain diseases passed the placenta to infect the foetus, and hence we might infer that intra-uterine infection was not impossible in syphilis.

To establish the fact that the mother had acquired syphilis during pregnancy and transmitted it to her foetus, Taylor, in the recent edition of his work, laid down a series of propositions which must be proved before the fact of such transmission could be accepted. It must be shown that the father was free from syphilis at the time of conception. The infection of the mother during pregnancy and her freedom from the disease previously must be proved beyond doubt. The child must have unmistakable lesions acquired without doubt before birth.

Dr. POST reported a case in which the following facts had been observed by himself and another physician: The previous good health of the mother was known; the primary sore had been seen on the mother during the seventh month of her pregnancy; the secondary eruption had occurred at about the average time, and had been in full bloom at the time of delivery, two months later; the child had been born apparently healthy, or at least without skin lesions, but a perfectly characteristic eruption and accompanying snuffles had shown themselves at the end of a week. The father accused his wife of having given him the disease when she first showed her local lesions, but he afterward confessed that he had acquired the disease outside of marital relations and had transmitted it to his wife. The only point where the evidence was assailable was the failure to examine the father as to the truth of his story.

Dr. Post reported three other cases in which syphilis of the child was thought to be due to inoculation of the mother during the course of her pregnancy, in each case by the father, who had acquired the disease after conception had taken place.

Dr. R. W. TAYLOR, of New York, said that Dr. Post assumed that syphilis was a bacterial disease. While the evidence of analogy strongly pointed to such an etiology, yet true scientific evidence to that effect was lacking. The placenta, as a rule, was a good filter and prevented the transmission of the red blood-corpuscles, which seemed to be the vehicles of the disease; but if this was so, why had the microbes of syphilis not been found in them? Women who were infected with syphilis during the first few weeks of pregnancy usually gave birth, toward the end of the fourth or fifth month, or perhaps later, to a macerated fœtus. When the infection occurred after the fourth or fifth month they might give birth to either a macerated fœtus or a puny, miserable child which at birth showed no evidence of the disease. Admitting that syphilis was due to a microbe which resided in the red blood-corpuscles and was prevented from coming in contact with the fœtus by the placenta, there was nothing to prevent the constant interchange of serum between mother and fœtus, and this carried with it the toxins of the disease. In the case reported by Dr. Post it was a matter of regret that he had not given the father a thorough examination to prove the truth of his statements. Assuming that the father's story was true, and that this was a reliable case of post-conceptional syphilis, it was probably to be attributed to the fact that the placenta of that mother had not been competent; that in the utero-placental circulation, owing to a rupture or thrombosis, or some other lesion, there had been an interchange of red blood-corpuscles and true syphilitic infection of the fœtus.

Dr. P. A. MORROW, of New York, said he had always accepted the theory that syphilis of the mother, acquired after conception, might be communicated to the fœtus, and also that the disease might be communicated to the mother by a syphilitic fœtus. He had observed a number of cases where the wife had been inoculated during pregnancy by a syphilitic husband who had contracted the disease after procreation, which resulted in an offspring with unmistakable evidences of syphilis. The theory that the placenta acted as an absolute filter, preventing contact of the syphilitic virus with the fœtus, did not, in his opinion, rest on sufficient evidence. He believed that almost all authorities at the present day recognized that the mother might receive infection from a syphilitic fœtus, and that the mother, healthy at the date of conception, might afterward contract syphilis and communicate it to her child *in utero*.

Dr. WHITE said there could be no doubt that the placenta acted as a filter. This had been shown experimentally in animals. The speaker expressed the opinion that, while the fœtus might be influenced by the toxins of syphilis, even to the point of death, he did not credit the theory that syphilitic manifestations in such a child after birth were due to the toxins alone, the placenta having acted as a competent barrier against the invasion of the bacteria themselves. One reason which might account for the rarity of post-conceptional syphilis probably was that the child, under these circumstances, must undergo a species of vaccination.

Dr. STURGIS said it was by no means certain that a microbe was the etiological factor of syphilis, and he had never been able to accept the theory that the placenta

acted in the capacity of a filter. It was well known that certain diseases could be transmitted by the mother to the child *in utero*, which compelled us to admit that if the placenta did act as a filter, it was a pretty poor filter, after all. Cases of syphilis had been reported where the mother had been infected as late as the eighth month, and he expressed the opinion that many similar cases escaped notice for the simple reason that it was exceedingly difficult to get an accurate history of such cases. In a pregnant woman the primary lesion was apt to escape notice or might be attributed to some irritation.

Dr. POST said that to make a plea for closer observation in these cases was one of the chief objects of his paper.

**Two Cases of Urethral Chancere with Unusual Secondary Symptoms.**—Dr. J. P. TUTTLE, of New York, said that in the first case the chancre had been situated within the urethra about three quarters of an inch back from the meatus. About ten days after its appearance the patient had complained of general malaise, his temperature had risen to 104° F., and he had an eruption almost typical of measles, except that it had been largely confined to the trunk and to the upper extremities and had the copper-colored tinge suggestive of syphilis. There had been no bronchial irritation. Later, distinct mucous patches had appeared on both tonsils. The eruption had lasted about two weeks. The patient had improved under specific treatment. The second case reported had been one of urethral chancre followed by muscular pains, which had been worse at night and had been so severe in character that hypodermic injections of morphine had been necessary to allay them. This patient had also had subsequently endocarditis and subsequently meningitis, from the effects of which he had not yet recovered. Dr. Tuttle said he was still in doubt as to whether the muscular pains and the cardiac and nervous symptoms had been specific in origin or due to rheumatism or some other constitutional diathesis.

(To be concluded.)

## AMERICAN GYNÆCOLOGICAL SOCIETY.

*Twenty-first Annual Meeting, held in New York, on Tuesday, Wednesday, and Thursday, May 26, 27, and 28, 1896.*

The President, Dr. WILLIAM M. POLK, of New York, in the Chair.

(Continued from page 96.)

**The Treatment of Extra-uterine Pregnancy.**—Dr. HOWARD A. KELLY, of Baltimore, read a paper with this title, in which he advocated vaginal puncture for the removal of the products of conception, and drainage. He based his advocacy of this method on an experience in thirteen cases, three of which were described in detail. In none of these cases had there been any unpleasant sequelæ. One patient who had been in uræmic coma for several days prior to the operation died a few days later, but there was no evidence that the operation was in any way responsible for her death. The method was applicable to the great majority of cases of extra-uterine pregnancy—i. e., to those of rupture in the early months. It was not suitable for the more advanced pregnancies, or for an extra-uterine pregnancy without rupture. Before doing the operation, a careful bimanual examination should be made, and the vagina thoroughly cleansed. With the finger in the vagina and against the gestation

sac, as a guide, a small opening should be made into the sac with scissors, and the opening stretched until it was from three to three centimetres and a half in diameter. Care should be taken to make the opening exactly in the axis of the pelvis, to avoid wounding the rectum. The sac should be washed out with normal salt solution before packing with gauze. The packing was not usually required after five days or a week. The great advantage of the operation was that none of the pelvic structures were removed, but the pelvic hæmatoma was nevertheless opened and drained. The greatest danger was from hæmorrhage, but he had met with only one case in which the hæmorrhage had been excessive. In this one, however, it was alarming. For this reason, the operator should always be prepared to open the abdomen, if required.

**The Treatment of Early Rupture in Extra-uterine Pregnancy.**—Dr. FERNAND HENROTIN, of Chicago, contributed a paper with this title. He divided the cases of early rupture, clinically, into: (1) complete rupture, with free, primary abdominal hæmorrhage; (2) incomplete rupture into the broad ligament. In the early weeks of pregnancy, the diagnosis of complete primary rupture was the diagnosis of intra-abdominal hæmorrhage. It was well to remember that a woman suffering from excessive and progressive hæmorrhage remained conscious after the first swoon, with the face constantly blanched, whereas the face of the woman who had only fainted flushed from time to time. The pains of rupture were likely to be successive, distinct attacks, with the patient well in the intervals. In tubal abortions, he would expect recurrence of the pains at short intervals up to the escape of the ovum. True surgery demanded the ligation of every bleeding vessel hæmorrhage from which might cause loss of life. Where the hæmorrhage was very free, the abdomen should be immediately opened and the vessel secured with two clamps. The hæmorrhage could often be controlled within five minutes in this way, and the entire operation completed in fifteen minutes. While the operation was going on an assistant might, if necessary, perform transfusion. If there were evidences of sepsis present, the abdominal cavity should be cleansed as thoroughly as was consistent with the condition of the patient, and drainage established. If the condition of the patient was very bad, it might be necessary to insert a large gauze drain. In aseptic cases it was better to close the abdomen after the removal of the large clots, as the shorter the operation and the less the manipulation of the peritoneum the better for the patient. Patients with acute, primary, free abdominal hæmorrhage should always be operated upon by abdominal section.

Dr. H. J. BOLDT, of New York, said that he did not think the treatment advocated in Dr. Kelly's paper would be very generally followed, on account of the very great risk of serious hæmorrhage. He thought also that many surgeons would, like himself, prefer to wait until shock had passed off before operating.

Dr. W. H. WATKINS, of Louisville, thought the treatment advocated by Dr. Kelly was correct for that special class of cases. The opening of Douglas's pouch was the best method in cases of severe hæmorrhage in which there was such profound shock that laparotomy would endanger life.

Dr. M. D. MANN, of Buffalo, reported a case of extra-uterine pregnancy in which, after the fetus had been removed through the vagina, there had occurred a frightful hæmorrhage. This had required very free packing

and stimulation of the patient, but in spite of all this improvement had only been temporary, and she had died in a short time. The autopsy showed a sac filling the pelvis and of such a size that an enormous quantity of packing would have been required to completely fill it.

Dr. CHARLES P. NOBLE, of Philadelphia, said he would hesitate to adopt this method except in an old case, because of the reported cases of severe hæmorrhage, and the more so as he had performed twenty-five successful abdominal sections for extra-uterine pregnancy. In the five cases of tubal abortion in which he had operated, the symptoms had tallied closely with the description given by Dr. Henrotin of primary abdominal hæmorrhage. A strong argument against the vaginal method of treatment was the possibility of leaving the ovum in the tube, ready to give rise to another hæmorrhage. If he found the abdomen filled with blood, unless the patient was in very bad condition, he would wash out the abdomen and leave in a considerable quantity of the fluid.

Dr. A. LAPHORN SMITH, of Montreal, said that his experience with the abdominal method in five cases of extra-uterine pregnancy had been very satisfactory. He had no dread of carrying out that method of treatment, but he would be utterly dismayed if required to do the vaginal operation.

Dr. B. F. BAER, of Philadelphia, said that, as the condition was much the same in extra-uterine pregnancy as in disease of the appendages, if abdominal section was the proper method for the former, he could not see why the vaginal method should be proper for the latter. He had never seen a patient with extra-uterine pregnancy die from the hæmorrhage, and in most instances he had not operated until the patient had recovered from shock.

Dr. J. E. JANVRIN, of New York, said that he had never operated upon a patient *à externis*, although he had successfully operated on several occasions while the hæmorrhage was going on. He had reported a case in which there had been a rupture of an artery lying on the gestation sac, with a fatal result. This had suggested to him the propriety of operating in cases in which there were symptoms of hæmorrhage prior to rupture of the tube, and he had twice successfully operated under these conditions.

Dr. SETH C. GORDON, of Portland, Me., said that in 1887 he had done the second successful operation in the United States for tubal pregnancy. Since that time he had operated in nine or ten other cases, and his experience had taught him that it was better to wait for reaction from shock before operating. He did not fear that the women would die from hæmorrhage so much as Dr. Henrotin did.

Dr. ASHTON said that the object of our treatment should be to control the hæmorrhage as quickly as possible, and for this reason he preferred the abdominal route. The irrigation of the vagina with hot water necessitated by the vaginal method was in itself sufficient to increase the hæmorrhage.

Dr. JOHNSTONE said that, as the danger increased with each attack of collapse, his rule was to operate immediately in cases in which there was a history of two or three previous attacks. The rule among general surgeons was to operate only after recovery from shock, and the same rule should apply in gynæcological practice.

Dr. WATKINS said that in eight out of eleven cases the vaginal route had been selected, and he believed that

had the abdominal route been selected in six of the eight cases the result would have been in all probability fatal.

Dr. ANDREW F. CERRIER, of New York, said that the majority of persons operated upon during collapse died. If shock and hæmorrhage were present, it made very little difference whether the case was one of ruptured ectopic gestation or ruptured ovarian cyst, for the treatment was the same.

Dr. J. TAOR JOHNSTON, of Washington, said that it did not seem rational to endeavor to resuscitate a person from shock while hæmorrhage was still active, because the measures employed for producing reaction were calculated to aggravate the hæmorrhage. A number of cases had been reported in which death had occurred while the surgeon was waiting for the disappearance of shock.

Dr. HENROTIN said that it seemed to him that if there was anything which should not be operated upon from the vagina it was an extra-uterine gestation sac. When such a sac had got beyond the active stage, there was no longer an extra-uterine pregnancy, and if it was situated low in the pelvis the vaginal method was appropriate. It was exceedingly risky to open into Douglas's pouch simply because a large boggy mass could be felt there, for there might be no distinct limiting sac, and the hæmorrhage might still be in progress. Under such circumstances, it was safer to perform laparotomy. As he had had a general surgical experience of sixteen years before taking up gynecology, he had learned not to wait for shock to pass off before operating. Of course, he did not mean by that that he would operate upon a patient presenting that condition of great restlessness so characteristic of impending death. He was firmly convinced that the surgeon could distinguish between simple swooning and collapse from excessive hæmorrhage.

**Suspensio Uteri with Reference to its Influence upon Pregnancy and Labor.**—Dr. CHARLES P. NOBLE, of Philadelphia, read a paper on this subject, and detailed the results of a collective investigation which he had been led to make by the occurrence of two difficult labors in his practice following this operation. One of these women had been delivered by podalic version, but the other had required a Porro operation. He had collected reports of 808 suspensions of the uterus in which one ovary had been allowed to remain, so that conception was possible. In only 56, or 6.9 per cent., did pregnancy occur. The investigation had led him to draw these conclusions: 1. That subsequent pregnancies are in most instances uncomplicated. 2. That uterine inertia is not infrequent. 3. That there is likely to be serious obstruction to labor if the fundus of the uterus is so fixed by adhesions that it can not rise out of the way. The foreign journals reported 165 pregnancies after the operation of suspensio uteri, with 17 abortions, 7 premature labors, and 60 labors at full term. Of these 60, 2 were artificial extractions, 8 forceps deliveries, 5 versions and 3 Cæsarean sections. There were 3 deaths from labor. The obstruction, Dr. Noble said, was due to the fact that in some instances the fundus and anterior uterine wall became imprisoned below the point of suture to the abdominal wall. Thus the hypertrophied fundus and anterior uterine wall might constitute a tumor, blocking up the pelvic inlet. It was evident from this that the mode of attachment of the uterus to the abdominal wall was of importance from the obstetrical standpoint. The procedure, therefore, which he now favored, was to make the lower angle of the incision stop an inch and a half above the pubes, and to pass the sutures through the an-

terior instead of through the posterior face of the fundus. Although Kelly had done a large proportion of these operations, in only one of his cases had difficult labor been reported.

(To be concluded.)

## Book Notices.

*Familiar Trees and their Leaves.* Described and Illustrated by F. SCHUYLER MATHEWS, Author of *Familiar Flowers of Field and Garden*, *The Beautiful Flower Garden*, etc. With over Two Hundred Drawings by the Author and an Introduction by Professor L. H. BAILEY, of Cornell University. New York: D. Appleton and Company, 1896. Pp. x-320. [Price, \$1.75.]

IN this handsome book, one sure, we think, to prove of great use, the author treats of one of the features of botany, a science to which more attention should be paid in courses preliminary to the medical curriculum. Among the trees whose leaves are described we find the following that have figured in the *materia medica*: The great-flowered magnolia, or bull bay, the sweet magnolia, or sweet bay, the tupelo, the sassafras, the chokecherry, the witch-hazel, the slippery elm, the chestnut, the beech, the willow, the poplar, the balm of Gilead, the white oak, the liquidambar, the flowering dogwood, the wahoo, the black haw, the white pine, the balsam fir, the larch, the juniper, and perhaps others that we have overlooked.

The book is not by any means a dry description of leaves; it teems with information on various incidental matters. It is written in popular style, but is none the less acceptable to those who view the subject from a scientific standpoint.

## BOOKS, ETC., RECEIVED.

*The Student's Medical Dictionary.* Including all the Words and Phrases Generally Used in Medicine, with their Proper Pronunciation and Definitions. Based on Recent Medical Literature. By George M. Gould, M. D., A. M., etc. With Elaborate Tables of the Bacilli, Micrococci, Leucomaines, Ptomaines, etc.; of the Arteries, Ganglia, Muscles, and Nerves; of Weights and Measures. Analyses of the Waters of the Mineral Springs of the United States, etc. Tenth Edition, rewritten and enlarged. Philadelphia: P. Blakiston, Son, & Co., 1896. Pp. xii-17 to 701. [Price, \$3.25.]

*Keil's Medical, Pharmaceutical, and Dental Register-Directory and Intelligencer.* With Special Medical, Pharmaceutical, and Dental Departments containing Detailed Information of Colleges, Hospitals, Asylums, Societies, with Street Lists, etc. For Pennsylvania, New York, New Jersey, Maryland, Delaware, and the District of Columbia. Fourth Edition. Philadelphia: Burk & McPetridge, 1896. Pp. xxxii-608.

*System of Surgery.* Edited by Frederic S. Dennis, M. D., Professor of the Principles and Practice of Surgery, Bellevue Hospital Medical College, etc. Assisted by John S. Billings, M. D., LL. D. Edin. and Harv.; D. C. L. Oxon.; Deputy Surgeon-General, U. S. A. Vol. IV. Tumors—Hernia—Surgery of the Alimentary Canal—Appendicitis—Surgery of the Liver and Biliary Passages—of the Uterus—of the Ovaries and Tubes—

Gynecological Surgery—Symphysiotomy—Surgery of the Thyreoid—Surgical Peculiarities of the Negro—Surgery of the Female Breast—Use of the Röntgen Rays in Surgery. Profusely illustrated. New York and Philadelphia: Lea Brothers & Co., 1896. Pp. 7 to 970. [Price, \$6.]

Manual of Midwifery. For the Use of Students and Practitioners. By W. E. Fothergill, M. A., B. Sc., M. B., C. M., late House Physician to the Simpson Memorial and Royal Maternity Hospital, and Gynecological Wards, Royal Infirmary, Edinburgh, etc. With Double Colored Plate and Sixty-nine Illustrations in the Text. New York and London: Macmillan & Co., Ltd., 1896. Pp. xviii-484. [Price, \$2.25.]

The Spas and Mineral Waters of Europe. With Notes on Balneo-therapeutic Management in Various Diseases and Morbid Conditions. By Hermann Weber, M. D., F. R. C. P., Consulting Physician to the German Hospital and to the Royal National Hospital for Consumption, Ventnor, etc., and F. Parkes Weber, M. D., M. R. C. P., Physician to the German Hospital. London: Smith, Elder, & Co., 1896. Pp. xii-380. [Price, \$2.]

Climate and Health. Edited under the Direction of Professor Willis L. Moore, Chief of the Weather Bureau, by W. F. R. Phillips, M. D. Vol. II, No. 3. A Summary of Statistics for the Four Weeks ending March 28, 1896. [United States Department of Agriculture.]

Transactions of the American Association of Obstetricians and Gynecologists. Volume VIII. For the Year 1895.

Transactions of the Medical Society of the State of New York, for the Year 1896.

Die Krankheiten der warmen Länder. Ein Handbuch für Aerzte. Von Dr. B. Scheube, Fürstl. Physikus und Sanitätsrat in Greiz, früherem Professor an der Medizinschule in Kioto, Japan. Jena: Gustav Fischer, 1896. Pp. vi-462.

Mitteilungen aus den Grenzgebieten der Medizin und Chirurgie. Herausgegeben von O. Angerer, München; E. von Bergmann, Berlin; P. Bruns, Tübingen; H. Curschmann, Leipzig; v. Czerny, Heidelberg; von Eiselsberg, Königsberg; W. Erb, Heidelberg; K. Gerhardt, Berlin; K. Gussenbauer, Wien; A. Kast, Breslau; Th. Kocher, Bern; R. U. Kronlein, Zürich; O. Leichtenstern, Köln; W. von Leube, Würzburg; E. Leyden, Berlin; L. Lichtheim, Königsberg; O. Madelung, Strassburg; J. Mikulicz, Breslau; B. Naunyn, Strassburg; H. Nothnagel, Wien; H. Quincke, Kiel; M. Schede, Bonn; K. Schoenborn, Würzburg; R. Stintzing, Jena; A. Wölfler, Prag; II. von Ziemssen, München. Redigiert von J. Mikulicz, Breslau und B. Naunyn, Strassburg. Erster Band. Zweites Heft. Mit 2 Tafeln und 1 Textfigur. Jena: Gustav Fischer, 1896.

What is the Best Method of Making and of Closing the Coliotomy Incision? By George M. Edebohls, M. D. [Reprinted from the *American Gynecological and Obstetrical Journal*.]

The Indication for Ventral Fixation of the Uterus. By George M. Edebohls, M. D. [Reprinted from the *Medical News*.]

Tumor of the Brain with Double Nasal Hemianopsia. By J. T. Eskridge, M. D., of Denver. [Reprinted from *International Clinics*.]

The Localization of Lesions in the Pons and Preoblongata. By Charles K. Mills, M. D., of Philadelphia. [Reprinted from *International Clinics*.]

The Association of Hemianopsia with Certain Symptom-groups, chiefly with Reference to the Diagnosis of

the Site of the Lesion. By Charles K. Mills, M. D., and G. E. De Schweinitz, M. D. [Reprinted from the *Philadelphia Hospital Reports*.]

Some Phases of Syphilis of the Brain. By Charles K. Mills, M. D. [Reprinted from the *Medical News*.]

Guide médical parisien. Publié par l'Association médicale. Faculté de médecine, école pratique, hôpitaux, hospices, amphithéâtre d'anatomie des hôpitaux, asiles d'aliénés, établissements spéciaux, cliniques particulières, etc. Paris: A. Maloine, 1896. Pp. 6 to 240.

Transactions of the Grant College Medical Society in Bombay, from January to December, 1895.

Thirty-second Report of the Trustees of the Boston City Hospital; with a Report of the Superintendent, the Medical and Surgical Statistics, Rules for Admissions and Discharges, Prospectus of Training School for Nurses, Rules for the Convalescent Home, etc. For the Year February 1, 1895, to January 31, 1896, inclusive.

First Annual Report of Lane Hospital, including Dispensary Clinics of Cooper Medical College as Out-patient Department, San Francisco, 1895.

Bulletin of the North Dakota Climate and Crop Service, for the Month of June, 1896. Vol. VI, No. 6. [United States Department of Agriculture.]

Post-nasal Adenoid Hypertrophy; with Especial Reference to the Importance of its Early Recognition by the Family and Physician. By J. E. Schadle, M. D., of St. Paul. [Reprinted from the *Laryngoscope*.]

Pharyngeal Tuberculosis. By Robert Levy, M. D., of Denver. [Reprinted from the *Denver Medical Times*.]

Orrhotherapy in Diphtheria. By E. Fletcher Ingals, M. D., of Chicago. [Reprinted from the *Journal of the American Medical Association*.]

Sponge Grafting in the Orbit for Support of the Artificial Eye. By E. Oliver Belt, M. D., of Washington, D. C. [Reprinted from *The Medical News*.]

## Miscellany.

**The Physician's Life and Work.**—Dr. William F. Barclay, of Pittsburgh, contributes an article to the *Maryland Medical Journal* for July 18th, of which the following is an abstract: There is no more arduous and responsible calling than that of the physician. The knowledge required to succeed in the practice of medicine and surgery is greater than that of any other profession. A natural adaptation which begets a love for the study of the science of medicine is an essential prerequisite. A vigorous and healthy body and mind and a self-sacrificing spirit are necessary to fulfill the requirements of a successful physician's life. To be willing at all times to do that for others which would not be asked or expected from them must guide and control the physician's spirit.

A sure confidence in the action of medicines in palliating and curing disease is the essential of a successful clinician. The power of medicines over diseased conditions is measured by their known actions and judicious application. Personal consecration to the work and study of the science of medicine is indispensable, even to the injury of health and personal comfort. Civilization has increased the demands made upon physicians by the people, and impossibilities are expected, and when all is done that science, reason, and experience can do,

very often reflection and injustice are the physician's reward. The moral force and courage which are required to sustain such injustice and ingratitude must be very great, and it is not to be wondered at that some of the ablest minds in the profession have turned to some other calling where these injustices are not known.

The highest moral character is the safeguard of the physician's life, and nothing short of irreproachable standing will meet the public demand. To know all things possible of the weaknesses, the passions, and the frailties of human character; to control personal feelings and sensibilities, and to respect the sacred duty of eternal silence are incumbent upon the physician toward those who come to him for counsel and help. It is not surprising that physicians become skeptical as to human character, and no doubt it requires, at times, the broadest charity to formulate a reasonable excuse for the depravity that almost daily comes to the physician's notice and consideration.

There is no part of a physician's career that requires more care than a fulfillment of the duties and obligations toward each other. To forgive and forget the injustice that may be done by members of the profession requires very often not a little sacrifice of personal feeling. It is to be regretted that the medical profession is divided into different schools whose theory and practice are entirely at variance and the conclusions arrived at diametrically opposed. The different schools of medicine are continually striving to advance the systems of practice to which they adhere, and, at the same time, they disparage all others, very largely to the discredit of the medical profession. Dr. Barclay believes that the regular school of medicine is the oldest and best, as it selects that which is established and discards that which is not based upon sound scientific truth and verified by practical experience. It is not his desire to disparage any system of practice that has reasonable tenets and recognition at the hands of the people, but to ask a just comparison and abide the discrimination which is certain to follow all things where vital questions are at issue. It is a better sign of preparation and fitness in physicians when the intelligent people are beginning to look into the character, education, and stability of young physicians and refuse to employ or encourage those not at least fairly well equipped by that which should be required. The advantages afforded in our country by our schools, hospitals, and other means of obtaining a thorough scientific medical education are unsurpassed.

At a time not long past, many physicians visited foreign countries for the purpose of attending schools of medicine supposed to be superior to those of the United States. This fallacy, at one time so prevalent, is no longer of pecuniary advantage to the American practitioner of medicine. Medicine and the sciences required are taught theoretically and practically as thoroughly in our country as anywhere in the whole world. The preparatory education of students of medicine is no doubt, in many instances, insufficient, and to this cause more than all others is attributable the want of preparation for successful practice.

The medical profession has not exercised the influence it should upon legislative bodies, in the enacting of laws for its own protection, as well as much that is demanded for the moral and physical welfare of the people.

The attitude of the physician before the people is that of a public servant, and it may be fairly stated that the opinion prevails that physicians are obliged by law to answer all calls and render services whenever it is

demanded of them. The press is not slow to publicly announce a refusal on the part of physicians to attend sick calls where the largest responsibilities are to be assumed without the least hope of pecuniary remuneration. Through the assumption that such services are obligatory upon physicians, great injustice is done to their professional standing. The proposition that professional duty begets menial service contemplates contempt and robs them of the legitimate respect due them from the people.

It may be fairly assumed that the education received in foreign countries by our citizens that have been transported to us has much to do with the assumption that free medical treatment is imperative. Free medical treatment in foreign countries is provided by the governments, and is liberally paid for, and is not gratuitous on the part of physicians. The guaranteed freedom of our institutions has wrought great injustice to physicians, as the laws in our country are formulated, as far as possible, on the basis that medical service to the poor should be gratuitous. Hospitals, almshouses, reformatories, and monopolies assume that medical services as far as possible should be secured without recompense; that the experience obtained in this way by physicians repays them for their time and services.

Physicians should demand a reasonable compensation for all services rendered, both public and private. The attending physicians and surgeons in some of our hospitals are generously paid, and it may be stated that these institutions command the services of the best men in the profession, and take away the reproach of charitable medical treatment that must fall upon the unfortunate poor. Medical charities are fast becoming a burden and reproach to the medical profession on account of the abuses that are practised, and the great injustice done to physicians, especially the younger members of the profession.

The medical profession does not offer so many opportunities to the student as it has in the past, and the number that succeed is yearly growing less, when we consider the multitudes that are crowding into our medical schools. The reports from our larger cities of the meager earnings of medical men are becoming alarming, as the facts would indicate that the larger part of the members of the medical profession do not earn a comfortable livelihood. It would seem that the profession has been hindered in its progress by a willingness on the part of its membership to serve charitable institutions, not to mention monopolies and associations where services are rendered to large numbers of persons, with the smallest possible consideration.

There is at present an inquiry in our larger cities as to the meager earnings of medical men and the complaint that the profession of medicine does not afford a comfortable living. The first and important cause is medical charities; that thousands are treated free of charge who are abundantly able to pay is established beyond all doubt by daily observations of physicians. The attendance given by physicians and surgeons to hospitals and institutions where charitable treatment is afforded requires much time and labor.

Justice demands that the unfortunate poor should be cared for by the State, but the burden should fall equally on its citizens. That physicians and surgeons should bear the burdens of medical service is unjust, and Dr. Barclay has the satisfaction of not having contributed to this imposition upon a great and honorable profession.

The never-pay class is a burden that must be borne,

but he prefers to choose from personal knowledge the objects worthy of charitable care and treatment.

The moral and legal responsibilities are the same for the pauper and for the millionaire, and in many instances the attention demanded is greater by the former case than by the latter. It requires discretion to determine when and where charity begins and imposition ends, and at all times it is best to err on the side of charity.

In justice to medical history we should study and perpetuate the histories of medical men and duly appreciate their lives and work. Our own country has produced an unusual number of distinguished physicians and surgeons, and it is a duty that we perpetuate their names and give them that place in history which their works demand. The work to be accomplished is so varied that it affords material for the different tastes and is suited to the conditions that meet the activities of the human mind. Diversified are the sciences that fit and enable men to pursue the practice of medicine, and it is not possible to know too much about that which concerns our lives and our work. We are members of a great and good profession, and we should exert our best efforts for the highest and noblest ends of the profession of general medicine.

**Menthol in the Treatment of Whooping-Cough.**—In the July number of the *West London Medical Journal*, Dr. Sidney A. Bontor says: Menthol, we know, has a definite action upon nervous tissue; it is most useful in relieving cases of pain due to increased sensibility—for instance, in neuralgia and in the pain of peripheral neuritis—and it has also a decidedly benumbing effect upon the terminal sensory nerve filaments, while the only effect it would be likely to produce, if absorbed, would be a beneficial one, for if taken internally it acts as an antispasmodic. It is used with benefit in relieving the spasms of hay fever, which is itself a reflex neurosis accompanied by a catarrh, and we know that in this condition its action is improved and the mucus most easily removed when it is combined with an oily menstruum; hence it seemed to him that such a solution might be expected to meet the indications for treatment which he had given.

So much, then, for the first and second stages; with regard to the third he has little to say; nothing can be better than the tonic plan of treatment usually adopted, which will restore the patient to health as quickly as possible; it may be remarked, however, that if the pathology given here is correct and the indications for treatment of the first and second stages are efficiently met, the cases of prolonged debility which occur so frequently after whooping-cough may be expected to become considerably diminished in number.

He has carried out this line of treatment in forty cases, most of them selected on account of their severity, and the result has been most satisfactory: in thirty-nine of them the benefit was decided, and in only one did the spray seem to have no effect; this, however, was a case complicated by acute bronchitis. One patient died, a weekly infant of only seven weeks, the immediate cause of death being convulsions in the third week of illness; in two the spray was not persevered with, although the paroxysms were relieved by it, because not having very severe attacks the parents thought the little smarting of the eyes an unnecessary infliction.

The manner in which the spray has been directed to be used is this: About twenty grains of menthol are dissolved in an ounce of liquid vaseline in an ordinary nasal

spray-producer; as soon as a paroxysm begins, or preferably as soon as the patient feels that one is impending, a fine cloud of spray is diffused in front of the face, the spray-producer being held about two feet away; by this means the air in front of the nose and mouth is saturated with the oily particles, and at each inspiration they are drawn into the air passages; this is quite painless, but occasionally a slight spasm of the glottis occurs. The effect of this inhalation is quickly seen, for the mucus is rapidly expectorated and the paroxysm is soon over, so that convulsions are less frequent and vomiting is rare, with the result that the patient loses his dread of taking food and eats with a better appetite, his general condition being thus kept at a much higher level—in fact, among the forty cases there were none of prolonged debility, none followed by gastro-intestinal catarrh, and none at present with tuberculosis. The author does not wish, however, to maintain that this result is wholly attributable to the form of treatment, because he practices in a healthy country district where the tubercle bacillus does not flourish and where the death rate is naturally low, but the results among patients in the same district treated by other methods have not been so satisfactory.

**The Clinical Significance of the Human Hand.**—Dr. Arthur S. Wohlmann, of London, contributes an article on this subject to the *Bristol Medical-Chirurgical Journal* for June, of which the following is an abstract:

The hand is so important a part of the human anatomy, it has played so large a part in the evolution of the human race, and has so largely contributed to the eventual triumph of man over his brute competitors, that it must always have a special interest for us.

The hand closely resembles the face. In each we find a large number of highly specialized small muscles in close connection with special sense organs; for what, after all, are the finger tips but special organs of touch? The remarks, then, that apply to the face apply, though perhaps with less force, to the hands. In the one case, by long custom we have learned to read the open page with some degree of ease and certainty; in the other, we are yet as little children stumbling over the alphabet. Perhaps after all, deep hidden in the muddy depths of charlatanism, there may be some pearl of truth in the study of palmistry! Indeed, these minuter scrutinies have already been largely utilized in criminal anthropology. The remarkable persistence of the epidermal lines of the finger tips, as pointed out by Galton, is made of everyday use in the identification of criminals, while Lombroso has written eloquently of the criminal expression shown by the hands and other parts, just as by the face, though Dr. Wohlmann thinks that most unbiased observers will allow that his enthusiasm outruns his discretion.

Nature does not bind herself down to always work according to one simple rule; a thousand influences are at work complicating the main issue, but all working to a definite conclusion, and all equally susceptible of scientific analysis. According as we look more closely into the matter, so does the element of chance as a causative factor diminish. Take the worn bones of a man who has long and incessantly toiled at the same trade; we soon come to recognize certain deformities peculiar to certain trades—ankylosis and false joints, erosions and bosses of bone, which we can readily see must necessarily have arisen as a consequence of the habitual assumption of the same position; in fact, we can often by the

deformities and so-called abnormalities of a skeleton determine the occupation of its erstwhile owner, just as a comparative anatomist may perform the sensational feat of building up an animal from a single bone. In this connection the well-known "housemaid's knee," "miner's elbow," and "carpenter's hollowed sternum" will at once flash across the mind.

Arbuthnot Lane has shown how in many, if not in most cases, the changes set down to osteo-arthritis are really due to a traumatic arthritis whose mechanism can be readily worked out on physical laws, and its relation shown to the patient's occupation or to a definite traumatism.

The diagnosis between gout, rheumatism, and rheumatoid arthritis is often one of extreme difficulty; and it is here that the observation of the hands is of the very greatest utility. The hand affected by chronic rheumatism may be distorted into all sorts of curious shapes, partly to be explained by the laws already given, partly due to pressure of bony outgrowths or to changes in ligaments and atrophy of supporting muscles. The hand erstwhile in the throes of rheumatoid arthritis may exhibit much the same lesions, due to the same forces at work, but above all, and masking all, is generally to be seen the original deformity—the characteristic swellings, once soft and impressible, now hard, calcareous, and fixed. Tubercular dactylitis may at first sight closely simulate rheumatoid disease in children; but the spindle swelling is caused by bone expansion, and is accompanied by suppurative, in both of which points it differs essentially from the latter disease. The other group, the rarer diseases, are as follows:

1. Page's disease (osteitis deformans). The cranium and long bones are the parts usually affected; and, though the hands sometimes show changes, these are hardly diagnostic and are very rare.

2. Acromegaly (of Marie). The large size of the hands is due to the excessive development of all the tissues. There is no appreciable increase of length, only of width and thickness, earning for the hands the epithets of "battledore" and "spadelike." The wrists are about normal. The nails are somewhat flattened, small, and longitudinally striated.

3. Hypertrophic pulmonary osteo-arthritis. The carpo-metacarpus, the hand proper, is about normal in size; but the fingers are enormously enlarged, the bulbous terminal phalanges being especially prominent. The nails are curved and striated, reminding one of the beak of a parrot. There is great enlargement of the wrists.

4. Myxœdematous hands may at first sight be mistaken for either acromegaly or hypertrophic pulmonary osteo-arthritis; but it will be seen that the skin of the other parts of the body is involved, and it is adherent to the deeper structures.

5. Vasomotor paralysis of the extremities. A few rare cases have been set down to this cause, and may somewhat resemble the foregoing; the presence of subcutaneous hæmorrhages may clear up the diagnosis.

6. The hands may exhibit marked changes in rickets, which in rare cases may simulate some of the former diseases; but an examination of the rest of the body will generally readily afford the data for a diagnosis.

7. In leontiasis ossea (Virchow) the hands may be affected; but for diagnostic purposes the changes are unimportant.

8. Nodosities of the fingers have been noted in connection with dilatation of the stomach.

The author does not pretend to have exhaustively treated even one aspect of the subject, and he has left untouched the clubbed fingers of emphysema, abnormal and extra digitation, Dupuytren's contraction, Raynaud's disease in connection with rheumatism, and all the thousand and one things that crowd to one's mind when it is allowed to rest on a subject. He hopes that this paper, which is rather of the nature of a sketch than a finished study, will tend to stimulate and systematize observation of these interesting cases.

#### Rules to be followed during the Course of Contagious Diseases.—The *Union médicale* for July 4th publishes the following rules which were recently adopted by the board of health of Paris, and were especially designed for the care of school children during the course of epidemic or contagious diseases:

1. The patient's room should be kept very clean, well aired, and properly heated, according to the various seasons and to the physician's directions.
2. There should be no carpet, no curtains, and as little furniture as possible in the room.
3. The bed should stand out in the room and not in an alcove.
4. No one should be allowed in the room except those who take care of the patient.
5. All food and drinks, except what is absolutely necessary for use, must not remain in the room, and what is not consumed by the patient must be burned or thrown into a jar kept exclusively for this purpose.
6. A bowl containing water should be placed near the patient, into which he may expectorate if necessary, as it is of the greatest importance to keep the sputa moist, for if they become dry they may spread through the air in the form of powder, and in this way cause disease. The contents of the bowl must be thrown into the jar.
7. This special jar must always be half filled with a solution of seven hundred and fifty grains of copper sulphate to a pint of water.
8. During the course of the disease all the furniture, etc., must be kept very clean and exposed every day to the light and sun for as long a time as possible.
9. No broom must be used to clean the room, as this would raise a dust which contained germs, and in this way the disease might be transmitted to other members of the family. Damp sawdust should be spread over the floor and afterward wiped up with a wet cloth, which should be allowed to soak in boiling water or be burned with the sawdust.
10. No bedding or clothing should be shaken out of the windows. It must be put into a box and sent to the proper place to be disinfected.
11. The dejecta, the urine, the sputa, etc., must be thrown into the special jar, the contents of which are to be emptied into a water-closet or into a hole in the ground, both of which are to be half filled with quicklime; they should also be at a proper distance from water courses and wells. The jar is then thoroughly cleansed before returning it to the room.
12. The nurse should not eat or drink in the same room with the patient, and before going to meals her hands must be carefully washed and the water thrown into the jar.
13. The water that is used for drinking, cooking, and cleaning must be boiled during the course of a disease or of an epidemic.
14. After convalescence all objects in the room must be subjected to thorough disinfection as soon as possible, whether they have been used by the patient or not.
15. The patient must not be allowed to go out until after a bath, or to return to school until forty days have elapsed after the onset of the disease (this applies to small-pox, scarlatina, and diphtheria), or sixteen days after measles.

These instructions, says the writer, are applicable to

adults, also, and may be followed in all epidemic and contagious diseases, such as typhoid fever, malaria, typhus fever, epidemic dysentery, phthisis, etc.

**Medicinal Hæmoglobin.**—In an article on this subject in the *Progrès médical* for July 4th Dr. Paul Cornet states that at the present time there is a hæmoglobin used for medicinal purposes which is said to be soluble. The product is shown ordinarily under the form of rather pretty crystals or small irregular grains of a somewhat reddish or violet tint, and they are brilliant and metallic. This hæmoglobin is often taken from the fresh blood of the horse, which is well defibrinated and put into deep bottles, where it becomes separated into several layers, the lower of which contains the globules and serves for the commercial preparation of the substance. For this purpose the globulous layer is treated with ether, then spread out on plates and rapidly dried in a stove. This hæmoglobin is then dissolved in water and afterward from fifty to sixty per cent. of its weight of a solution of gum arabic is added to it; it is then spread on glass plates and again put into the stove to dry. This hæmoglobin, however, says the author, is not soluble in alcohol, because of the gum which is used in its preparation and the albumin which is retained by the globules, so that it must be dissolved first in water and wine added afterward; this, however, forms an abundant precipitate which takes away from the hæmoglobin an essential part which can not be used, and the practical conclusion is that the elixir and the wine of hæmoglobin are very poor pharmaceutical preparations, because there is very little active principle in them.

There is another preparation, says the author, which is more soluble and more assimilable, however, which is obtained by allowing the blood to remain in an extremely cold jar. The lower layer is treated with ether and washed several times in order to free the globules from fatty materials and from albuminoids. Desiccation is effected *in vacuo*, care being taken to maintain an unvarying low temperature. Under these conditions a hæmoglobin is obtained which is remarkably soluble in all kinds of wine, and limpid solutions may be made which are of a very deep red color and contain from three ounces and a half to nearly five ounces of hæmoglobin to the pint. This soluble preparation of hæmoglobin is of a reddish-brown color, somewhat like that of iron subcarbonate. With distilled water it forms limpid solutions of a beautiful reddish-purple color. If ninety per cent. alcohol is added to this preparation, it becomes turbid and throws down a blood-colored deposit; the commercial preparation, however, under the same conditions, shows a thick deposit, the color of which resembles that of rust. This demonstrates, says Dr. Cornet, that when hæmoglobin is dried at an elevated temperature the globules are altered by the iron oxide being set free.

**Sesame Oil.**—Dr. R. Stüve, of Professor von Noorden's division of the Municipal Hospital in Frankfurt on the Main (*Centralblatt für die gesammte Therapie*, June, 1896), has been experimenting with sesame oil. He first reports on its use as a substitute for cod-liver oil. He employed it in all kinds of cases, several hundred in number, in which cod-liver oil was indicated. The patients were of all ages, from six months upward to old age, but the majority of them were children between four and fifteen years old weakened by acute infectious disease or by scrofula. As a rule, the amount of sesame oil given daily was from two to three tablespoonfuls, but in many cases it was twice as large. On account of

its absolute lack of odor and its almost entire tastelessness, it was seldom necessary to use anything in the way of a flavor; a swallow of coffee or of cognac or a bit of bread was always sufficient. Many patients objected to the taste at first, but their repugnance was soon over.

The oil was particularly well borne generally, but it disagreed with a few persons, causing palpitation and nausea or vomiting in some and diarrhoea in others, so that its use had to be discontinued. On the whole, the author regards it as one of the best borne and most easily digested of fats. It will often agree in cases in which cod-liver oil is contraindicated, such as those of phthisis with obstinate diarrhoea, which sesame oil aggravates only in very few instances and mitigates in the majority by improving the patients' general condition. Not less favorable was its action in cases of chronic intestinal catarrh with habitual constipation and overproduction of mucus in the lower portion of the intestinal tract.

The oil was strikingly well borne in cases of disease of the stomach. Emaciated persons with gastric catarrh, excessive acidity, ulcer of the stomach, or nervous dyspepsia took daily from one to two ounces of sesame oil without experiencing any ill effect. In other patients with sensitive digestive organs the oil was well borne; above all, in those with acute fevers. Patients with febrile pleurisy, septic fever, and especially typhoid fever, even children, bore the oil well. In some cases it was used by subcutaneous injection, in doses of from fifteen to a hundred cubic centimetres.

Administered as a nutrient enema, sesame oil was not found to give good results; it would remain in the rectum for from twelve to twenty-four hours and then be expelled. The author thinks it would act better as a substitute for olive oil in the enemata treatment of habitual constipation; it is at least, he says, quite as good as olive oil for this purpose. Only the finest and purest sesame oil is suitable for medicinal use. The author has had the best results with an oil furnished by the firm of Speyer & Grund, of Frankfurt.

**Eucasin.**—In the *Centralblatt für innere Medizin* for July 11th, Dr. A. Cohn, of Adlershof, describes this nutrient preparation, made from milk, as a white powder of a somewhat gritty aspect, without any special taste, and having a faint odor of milk. Mixed with cold water, it forms a gelatinous mass. On shaking it with boiling water, a uniform clear-white solution is formed. This tastes like groats, but it is more glutinous. The author says that eucasin is an acid ammonium salt of casein.

He has used it in the form of a mush of oatmeal or rice, to each plateful of which a teaspoonful of eucasin has been added, together with a little salt. This mixture is readily taken two or three times a day. A chocolate preparation containing twenty per cent. of eucasin has been put on the market by Hartwig & Vogel, of Dresden. Dr. Cohn gives brief accounts of several cases in which he has found eucasin of advantage, including cases of pulmonary and laryngeal tuberculous disease, anæmia, peritoneal irritation, typhlitis, parametritis, and perimetritis. Particularly striking were the effects of its employment in a case of acute anæmia following abortion.

**Thyroid Feeding as a Means of Dwarfing the Fœtus.**—At a meeting of the Vienna Geburtshilflich-gynäkologische Gesellschaft held on March 3d, reported in the *Centralblatt für Gynäkologie* for July 4th, one of the members related the case of a woman whom he had attended in labor the year before. She had an infundibuliform pelvis on which the spines of the ischia encroached decidedly, and there was an exostosis on the right ilio-

pubic tubercle. The fœtus was very large, weighing over nine pounds. After repeated attempts at extraction by the high forceps operation, the reporter had had to resort to craniotomy, and even after that had been performed the extraction of the child had been very difficult owing to its size. The woman had since come under his care in the fourth month of pregnancy. In pursuance of Prochownik's idea of restricting the growth of the fœtus by dieting, he had, from the beginning of the fifth month, employed thyroid feeding, giving one tablet a day. At first the woman had increased in weight, but in the later period of the treatment a loss of weight was observed each week. It was judged that the growth of the fœtus was well under control, and the pregnancy was allowed to go to term. When labor came on, the head was driven into the pelvic cavity, but its further advance was impeded by the projecting spines of the ischia. On that account the forceps had to be applied, the head having rotated normally, and a living child weighing about six pounds and a quarter was easily extracted.

The reporter admitted that it was very questionable whether this difference in the weight of the two children was due to the thyroïdin treatment alone, but he thought the case was an interesting one. The treatment had been begun in two other cases of pelvic contraction that had since come under observation at a sufficiently early stage of gestation, and from the results in those cases some opinion might be formed as to whether the dwarfing of the fœtus in the case related had been *post hoc* or *propter hoc*.

**Medical Magic.**—In the *Gazette hebdomadaire de médecine et de chirurgie* for July 12th there is an account of a trial in which the plaintiff was the wife of a porter and the defendant a non-licensed healer who practised her art in a somewhat peculiar fashion. The plaintiff stated that she and her husband had gone to consult this woman about a tumor with which the man had been suffering. The woman had examined the arm, made the sign of the cross over it, and pronounced some Latin words. The judge then asked the plaintiff to repeat the words, but she said she could not remember them perfectly, but thought they were somewhat like this: Roupoupiou—tralala—badabournorum. Afterward, the plaintiff continued, the woman had pierced the tumor with a needle, and during the operation she had made the patient hold a cooked leek in the right hand and a lighted candle in the left. Furthermore, she had directed the patient to anoint the tumor with an ointment every morning, and to wash the arm with rabbit's blood.

The plaintiff stated that her husband had not recovered, and that it had been necessary to take him to a hospital, where he still remained.

**Codeine as an Adjuvant of Dilatation of the Glottis in Croup.**—The *Gazette médicale de Paris* for July 11th contains a report of a recent meeting of the Société médicale des hôpitaux, at which M. Variot read a paper in which he advocated the use of codeine as an adjuvant of dilatation of the glottis in croup. It had been ascertained, he said, that if the tube was left a few minutes in the larynx of children who had violent spasms of the glottis, accompanied by suffocation, and if it was withdrawn immediately, a cessation of the phreno-glottic spasm would be obtained, with a relative regulation of the respiratory movements. Sometimes the spasm yielded, and the regulation of respiration was definitive. It seemed to him that this active and extemporaneous dilata-

tion of the glottis was more efficacious in children over two years of age, and in cases in which the diphtheritic laryngitis was not very membranous, with a hoarse cough and a clear voice. Spasm of the glottis was then a predominant and threatening element in croup. If the vocal cords were dilated by catheterism, immediate and more or less persistent relief would be produced after the withdrawal of the tube. The return of the spasm, however, was to be feared after dilatation with O'Dwyer's tube.

Children over two years of age were less subject to laryngeal troubles, and extemporaneous catheterism of the larynx might be substituted, at least in certain cases, for permanent catheterism.

The serious inconveniences caused by the tube remaining in place, such as its obstruction by mucosities, troubles of deglutition, and cricoid ulcerations, were thus avoided.

M. Variot thought that quieting agents for the nervous system might be useful by causing a definitive reduction of the nervous phreno-glottic apparatus after the dilatation when the spasm was very intense. It seemed to him that a judicious administration of codeine had the effect of quieting the spasmodic attacks and probably, also, of preventing a return of severe paroxysms of suffocation after the extemporaneous dilatation of the glottis. He had made a few experiments with this method, and the results had been very successful.

**Injections of Artificial Serum.**—At a recent meeting of the Académie de médecine, a report of which appears in the *Gazette hebdomadaire de médecine et de chirurgie* for July 2d, M. Pozzi made a report on M. Duret's work in regard to the treatment of septicæmia following operations by means of injections of artificial serum. He showed that this practice was widespread in hospitals in Paris; he also alluded to a recent discussion on the subject before the Société de chirurgie in connection with a case which had come under M. Berlin's observation (*Mercure médical*, 1895, p. 620), and he had concluded then that this method of treatment was sometimes very efficacious, and one to be recommended. M. Pozzi gave the preference to subcutaneous injections of a solution of sea salt in the proportion of seven to a thousand.

M. Reclus stated that he had experimented recently with intravenous injections on a boy who had had an attack of hydrophobia. The treatment had not been begun until two weeks after the boy had been bitten, but an injection of nearly five ounces had seemed to quiet the patient, who died, however, two hours later.

M. Championnière had also obtained good results in the treatment of anæmia and shock, but not in septicæmia. M. Pinard expressed the same opinion, and recalled the fact that M. Dastre and M. Loye had shown, in 1889, that in septicæmia there was nothing to be gained by lavage of the blood.

M. Pozzi thought, however, that the successful results of this treatment could not be denied, in M. Berlin's observation particularly. These injections, he said, favored phagocytosis and diuresis, which exerted a favorable influence in certain forms of septicæmia and prevented a fatal result.

M. Championnière was inclined to doubt these facts, especially M. Berlin's. He thought intravenous injections were not harmless, and that, at the present day, there was danger of the method being abused.

M. Dumontpallier thought that injections of ether were sufficient, and said he would not allow any surgeon to practise intravenous injections on him.

M. Pinard stated that he had seen recovery follow subcutaneous injections in seventeen women whose condition had been such that, before the employment of this method, death would probably have resulted.

M. Tarnier had also obtained good results in cases in which by the old method of treatment death would certainly have resulted. With regard to the question of septicæmia, he had never employed this method; he simply recalled the fact that formerly women who had had severe attacks had been cured; that to-day septicæmia was rarer; that it should not always be pronounced fatal, or cry *post hoc ergo propter hoc* when recovery followed the injections of serum.

M. Péan said that, on the whole, all were agreed as to the usefulness of subcutaneous injections, and the precaution with which intravenous injections should be administered.

**The Treatment of Ascites by Injections of Oxygen into the Peritonæum.**—At a recent meeting of the Lyons Société nationale de médecine, a report of which appears in the *Provincie médicale* for July 4th, M. Teissier related the case of a woman who came under his care for ascites with generalized oedema. He treated her according to M. Potain's method of abdominal puncture followed by injections of oxygen into the peritonæum. At the first puncture about fourteen pints were withdrawn, but no amelioration occurred, as the liquid collected again in six days. A second puncture was then made and followed by the injection of 1,300 cubic centimetres of oxygen. The operation was very well borne, and it did not provoke any pain or local reaction; there was also complete absence of fever during the following days.

The abdominal circumference diminished from 128 to 102 centimetres, and the oedema of the lower limbs disappeared very rapidly. The oxygen was easily absorbed by the peritonæum. For some days there was some gurgling, but this disappeared at the end of eight or ten days. At the present time the abdomen still measured 102 centimetres and sonorousness existed everywhere, even in the iliac fossa when the patient lay on her side. She was able to get up every day and walk in the open air. These results had been obtained in three weeks.

The patient entered the hospital suffering from alcoholic cirrhosis, and after her entrance the liver increased in size and cardiac symptoms presented themselves. The diagnosis, said M. Teissier, might be open to discussion, but that was of secondary interest only; he presented the case because he had seen the grave symptoms disappear in three weeks under the influence of an injection of 1,300 cubic centimetres of oxygen into the peritonæum.

**The Thyreoid Treatment in the Idiopathic Tetany of Children.**—The *Presse médicale* for July 11th contains an abstract of an article which was published in the *Riforma medica*, Nos. 115 and 116, 1896, in which the writer states that Dr. Leone Maestro has experimented with this method of treatment in three cases of tetany. The thyreoid gland was given raw or slightly cooked. Small doses were given in the beginning and gradually increased until the amount of thirty grains a day was reached. The results obtained were very satisfactory in the three cases, and the author felt justified, in spite of the limited number of observations on record, in forming the following conclusions: 1. The administration of the thyreoid gland is extremely useful in the treatment of idiopathic tetany in children, as it always diminishes the intensity and the frequency of the attacks,

and shortens the duration of the disease; it also notably hastens the arrival of the latent period which precedes recovery. 2. The treatment is well tolerated by the children. 3. The organic exchanges, the digestive functions, and diuresis are not notably influenced by this mode of treatment. 4. The circulatory and respiratory functions are accomplished normally during this treatment. 5. In very young children, on account of their perfect tolerance, it is useful to administer the thyreoid gland, raw or slightly cooked, internally. 6. With the exception of certain peculiar cases, it is not necessary to suspend the treatment from time to time. 7. The daily dose is from thirty to sixty grains. 8. This treatment is not opposed to the symptomatic treatment, as it does not present any incompatibility with the methods ordinarily employed.

#### The Action of Strychnine in Chloroform Collapse.

The *Union médicale* for July 11th contains the following abstract from an article by Evenhoff, which was published in *Veatch*: Arrest of the heart is one of the most important causes of collapse during chloroform anaesthesia. The paralysis of the vaso-motor centre which is provoked by the latter brings about the rapid fall of the blood pressure, and this fall, by depriving the cardiac muscle of its excitant, is one of the causes of the arrest of the heart. As the result of experiments, Professor Bobroff proposed making subcutaneous injections of sodium chloride in cases where the pulse was feeble during chloroform anaesthesia. Evenhoff's experiments with strychnine were as follows: Tracheotomy was practised on dogs, and a tube was introduced into the larynx and put in communication with a small bottle which contained chloroform. Artificial respiration was made in such a way that the air passed through the bottle, and it could be charged or not with chloroform. Before chloroformization the pressure was noted, then the air, charged with chloroform, was injected and, when the pressure fell to 0, pure air was injected and an intravenous injection of from two to three milligrammes of strychnine was administered. When the pressure finally became normal the animal again received inhalations of chloroform. In this way the action of the chloroform before and after the injection of strychnine was ascertained. The results of these experiments showed that, owing to these injections, dogs, which usually tolerated chloroform badly, could support the drug without inconvenience for a greater length of time. The favorable action of strychnine on chloroformization was thus demonstrated. Strychnine, however, has two inconveniences: it may possibly provoke a tetanoid attack, and, given in the dose employed by Evenhoff, it increases parenchymatous hamorrhage.

**A Curious Example of Old-World Pharmacy** is given, says a daily contemporary, in one of the letters which the Historical Manuscripts Commission has found in the valuable collection of documents preserved by the Marquis of Salisbury in Hatfield House. Toward the end of the sixteenth century Sir Henry Unton was sent on a mission to the French king in Paris, and there became ill; whereupon the physician of the royal house gave him a "a confectio alcarinas, compounded of musk, amber, gold, pearl, and unicorn's horn, with pigeons applied to his side, and all other means that art could devise, sufficient to expel the strongest poison, and he be not bewitched withal." It is almost needless to add that after the administration of this extraordinary medicine the ambassador promptly expired.—*British and Colonial Druggist*.

## Lectures and Addresses.

### LECTURES ON ANGINA PECTORIS AND ALLIED STATES.\*

By WILLIAM OSLER, M.D.,

PROFESSOR OF MEDICINE, JOHNS HOPKINS UNIVERSITY, BALTIMORE.

#### LECTURE I.—INTRODUCTION.

THE history of the recognition of the disorder known as angina pectoris is connected with the names of three celebrated men—Heberden, Jenner, and John Hunter.

On July 21, 1768, Heberden read, at the Royal College of Physicians, a paper entitled *Some Account of a Disorder of the Breast*, which was published in vol. ii of the *Medical Transactions* of the College of Physicians, 1772. An extract from the original description must be quoted: "There is a disorder of the breast, marked with strong and peculiar symptoms, considerable for the kind of danger belonging to it. . . . The seat of it and sense of strangling and anxiety with which it is attended may make it not improperly be called angina pectoris.

"Those who are afflicted with it are seized while they are walking, and more particularly when they walk soon after eating, with a painful and most disagreeable sensation in the breast, which seems as if it would take their life away if it were to increase or to continue; the moment they stand still all this uneasiness vanishes. In all other respects the patients are at the beginning of this disorder perfectly well, and, in particular, have no shortness of breath, from which it is totally different."

Subsequently, in the celebrated *Commentaries* upon which our grandfathers in the profession were educated, Heberden gave a fuller account of his experience with the disease. The name which he adopted can not be regarded as altogether satisfactory, since it was already in use in designating affections of the throat, with which its literal meaning—a strangling—is much more in harmony. In one sense, however, the term is fairly appropriate, since, as noted by Gairdner, the words anxiety and anguish, expressive of two of the most prominent features of the disease, have a derivation from the same word.

In 1773, John Hunter had his first attack, which was graphically described by his nephew, Everard Home: "While he was walking about the room he cast his eyes on the looking-glass, and observed his countenance to be pale, his lips white, giving the appearance of a dead man. This alarmed him and led him to feel for his pulse, but he found none in either arm; the pain continued, and he found himself at times not breathing. Being afraid of death soon taking place if he did not breathe, he produced the voluntary act of breathing by working his lungs by the power of the will." In 1776 he had a

second attack, and when convalescent he visited Bath. Here he was seen by his friend and pupil, Edward Jenner, of Berkeley; and one of the most interesting and sagacious letters of that distinguished man was written to Heberden, giving his diagnosis of John Hunter's case, and suggesting, for the first time, the probable association of disease of the coronary arteries with angina pectoris. The letter is worth quoting in full: "When you are acquainted with my motives, I presume you will pardon the liberty I take in addressing you. I am prompted to it from a knowledge of the mutual regard that subsists between you and my worthy friend Mr. Hunter. When I had the pleasure of seeing him at Bath last autumn I thought he was affected with many symptoms of the angina pectoris. The dissections (as far as I have seen) of those who have died of it throw but little light upon the subject. Though, in the course of my practice, I have seen many fall victims to this dreadful disease, yet I have only had two opportunities of an examination after death. In the first of these I found no material disease of the heart, except that the coronary artery appeared thickened.

"As no notice had been taken of such a circumstance by anybody who had written on the subject, I concluded that we must still seek for other causes as productive of the disease; but, about three weeks ago, Mr. Paytherus, a surgeon at Ross, in Herefordshire, desired me to examine with him the heart of a person who had died of the angina pectoris a few days before. Here we found the same appearance of the coronary arteries as in the former case. But what I had taken to be an ossification of the vessel itself, Mr. P. discovered to be a kind of firm, fleshy tube, formed within the vessel, with a considerable quantity of ossific matter dispersed irregularly through it. This tube did not appear to have any vascular connection with the coats of the artery, but seemed to lie merely in simple contact with it.

"As the heart, I believe, in every subject that has died of the angina pectoris, has been found extremely loaded with fat, and as these vessels lie quite concealed in that substance, is it possible this appearance may have been overlooked? The importance of the coronaries, and how much the heart must suffer from their not being able duly to perform their functions (we can not be surprised at the painful spasms), is a subject I need not enlarge upon, therefore shall just remark that it is possible that all the symptoms may arise from this one circumstance.

"As I frequently write to Mr. H. I have been some time in hesitation respecting the propriety of communicating the matter to him, and should be exceedingly thankful to you, sir, for your advice upon the subject. Should it be admitted that this is the cause of the disease, I fear the medical world may seek in vain for a remedy.

\* Delivered to the Post-graduate Class, Johns Hopkins Hospital.

\* Baron's *Life of Jenner*, London, 1827.

and I am fearful (if Mr. Hunter should admit this to be the cause of the disease) that it may deprive him of the hopes of a recovery."

In another letter \* Jenner gives as his reasons for not publishing his views earlier an anxiety lest they should be a source of annoyance to his friend Hunter. "Soon after Mr. Paytherus met with a case. Previous to our examination of the body I offered him a wager that we should find the coronary arteries ossified. This, however, proved not to be exactly true; but the coats of the arteries were hard. . . . At this time my valued friend, Mr. John Hunter, began to have the symptoms of angina pectoris too strongly marked upon him; and this circumstance prevented any publication of my ideas on the subject, as it must have brought on an unpleasant conference between Mr. Hunter and me." He says that Mr. Cline and Mr. Home did not think much of his views. "When, however, Mr. Hunter died, Mr. Home very candidly wrote to me, immediately after the dissection, to tell me I was right."

The further details of Hunter's remarkable case are always referred to. From 1785, when he had a severe illness, the attacks became increasingly frequent, and were brought on particularly by exercise and by worry and anger; and, indeed, he was accustomed to say "that his life was in the hands of any rascal who chose to annoy and tease him." During the last few years of his life, though he did a large amount of work, the attacks seem to have been very frequent, and would come on after very slight exertion and while he was operating. As he had himself predicted, death came suddenly, in consequence of a fit of temper at a meeting of the governors of St. George's Hospital, October 16, 1793. When contradicted flatly, he left the board room in silent rage, and in the next room gave a deep groan and fell down dead. The coronary arteries were found to be converted into open bony tubes, and the aorta was dilated.

Attempts have been made by French writers to claim the priority in the description of the disease for Rougnon, professor of medicine in the University of Besançon. In a letter addressed to M. Lorry, dated February 23, 1768, he describes the case and circumstances of the death of a Captain Charles. The patient had become asthmatic, and on walking fast had a sort of suffocation. Six weeks before his death he had complained to M. Rougnon of "*une gêne singulière sur toute la partie antérieure de la poitrine en forme de plastron.*" The attacks evidently occurred with great suddenness, and disappeared with equal abruptness. The chief stress is laid upon the feeling of suffocation, but it is evident that associated with it there was pain of great intensity; "*seulement un douleur gravative dans le sein du cœur, lorsqu'il éprouvait ses suffocations.*" Captain Charles died very suddenly, shortly after dining with his friends. The pericardium was fatty; the heart was

large; there were no valvular defects; the coronary veins were enlarged "prodigiously"; no mention was made of the condition of the coronary arteries. Rougnon lays stress upon the obstruction in the lungs and excessive ossification of the cartilages. He confesses, however, that the condition was very puzzling, and the autopsy not at all satisfactory to his friends: "*M. Charles est mort, disoient-ils, parce qu'il est mort.*"

I can not agree with Professor Gairdner, who says that "there was no trace of anything like a clinical description of angina pectoris in M. Rougnon's letter." \* The suddenness of the attacks, the pain in the region of the heart, the abrupt termination, and the mode of death—during exertion after a full meal—favor the view that the case was one of true angina.

To Morgagni, not Rougnon, is due the credit of the first description of a single case. In the splendid section on aneurysm of the aorta, he describes angina pectoris accurately in Case V, referring to the paroxysms, the pain, the difficulty of breathing, the numbness of the left arm, and the effect of exertion. I read you here extracts from the case.

"A lady, forty-two years of age, who for a long time had been a valetudinarian, and within the same period, on using pretty quick exercise of body, she was subject to attacks of violent anguish in the upper part of the chest on the left side, accompanied with a difficulty of breathing and numbness of the left arm; but these paroxysms soon subsided when she ceased from exertion. In these circumstances, but with cheerfulness of mind, she undertook a journey from Venice, purposing to travel along the continent, when she was seized with a paroxysm, and died on the spot. I examined the body on the following day. . . . The aorta was considerably dilated at its curvature; and, in places through its whole tract, the inner surface was unequal and ossified. These appearances were propagated into the arteria innominata. The aortic valves were indurated." He remarks: "The delay of blood in the aorta, in the heart, in the pulmonary vessels, and in the vena cava, would occasion the symptoms of which the woman complained during life; namely, the violent uneasiness, the difficulty of breathing, and the numbness of the arm."—(Cooke's *Morgagni*.)

There are those, indeed, who regard Seneca as the first to describe the affection, in the remarkable account which he gives of his own disorder. With this view Forbes and Gairdner agree, but Parry and Stokes do not. I quote from Parry the following translation of part of Seneca's graphic account: "The attack is very short and like a storm. It usually ends within an hour. I have undergone all bodily infirmities and dangers; but none appears to me more grievous. Why not? Because to have any other malady is only to be sick; to have this is to be dying." Seneca states, too, that his physicians called the disease a *neustitia nervosa*.

The literature of angina pectoris has become very voluminous. English writers have contributed most largely to the clinical description of the disease. Per-

\* PATEY, *An Inquiry into the Symptoms and Causes of the Syncope Anginosæ, commonly called Angina Pectoris*, 1799.

\* *Lancet*, 1891, i, p. 561.

haps the two most valuable articles are lectures xxxvii and xxxviii in Latham's *Clinical Medicine*, which you will find in vol. i of the New Sydenham Society edition of his work; and Professor Gairdner's essay in Reynolds's *System of Medicine*. The best recent expositions in French and German are to be found in Huchard's *Traité clinique des maladies du coeur*, second edition, 1893 which gives a most exhaustive account of the various forms of angina, and O. Rosenbach's *Die Krankheiten des Herzens*, 1893. I pass about for your inspection a number of the monographs and journal articles which I have collected on the subject. Parry's essay has become very scarce, but it is in all the larger medical libraries. Rougnon's letter, published at Besançon, 1768, is still more rare. The copy in the Surgeon-General's Library is the only one I have ever seen. I would ask you to look at the first part at least of these fly leaves, which I picked up in an old book shop a few years ago. It is a letter to Dr. Heberden from a man who signs himself "Unknown," descriptive of his own case. He had seen, in the *Critical Review*, an extract from Heberden's original paper, and, recognizing his malady, he wrote in the letter one of the very best accounts which exists in the literature. It is particularly noticeable for two things: He clearly dissociated the pain of the attack from the *angor* or mental feature, and he first made use of the now hackneyed phrase describing the latter aspect as "an universal pause within me of the operations of Nature." Expecting a sudden death, he left orders that Heberden should examine his body. Within three weeks from the writing of the letter the dissection was made by John Hunter.

DEFINITION.—In the consideration of a disease it is well, if possible, to start with a clear understanding, or at least some concise statement, of its nature, and of the characters of the manifestations by which it is recognized. With some disorders this is a very easy matter. For example, insufficiency of the aortic valves is a clearly defined affection, with, it is true, a diverse ætiology, a varied anatomical picture (from a trifling curl of the edges of a valve, to a clean shaving of a segment from the aortic ring); but with all its variations there are associated definite sequences and well-characterized signs.

Angina pectoris is not a disease, but a syndrome or symptom group (without constant ætiological or anatomical foundations) associated with complex conditions, organic or functional, of the heart and aorta. Pain about the heart of an agonizing character, occurring in paroxysms, is the dominant feature of all varieties of the syndrome. Used to define paroxysmal attacks of pain in the chest—breast-pang—we employ the term generically, qualifying the varieties by such names as true, false, hysterical, and vasomotor.

Before passing to the discussion of the varieties of angina pectoris let me refer briefly to the subject of

HEART PAIN.—Disturbance of sensation is a most inconstant symptom of heart disease; the gravest affec-

tions are often painless; the most trifling may present the features of an intense neuralgia; while a very limited lesion may have as its sole manifestation paroxysms of agonizing pain.

The following abnormal cardiac sensations may be recognized:

1. Consciousness of the heart's action; a fluttering, a sense of goneness, the indefinable uneasiness associated with palpitation, a sense of tension in the chest with gasping, all or some of which are common phenomena in emotional states, in indigestion, neurasthenia, and hysteria.

2. Pain—darting, stabbing, tearing or boring, dull and heavy, or acute and piercing, steady or paroxysmal—varying in grades of intensity and in duration, often transient and trifling, as in dyspepsia and the tobacco habit, more enduring and severe in hysteria and neurasthenia, and occurring in paroxysms of an agonizing, intolerable character in the forms of angina. It often radiates over the area of distribution of certain of the cervical and dorsal nerves.

3. There is an element peculiar to certain conditions of the heart, often associated with, but which can not itself be properly characterized as pain—indeed, the patient often expressly states that it is not of the nature of physical pain—a sense of imminent dissolution, a mental anguish, which has been variously expressed by patients and writers as a pause in the operations of Nature, the very hand of death, *angor animi*, etc. This it is which constitutes the special feature in a majority of the cases of true angina.

CLASSIFICATION OF THE FORMS OF ANGINA PECTORIS.—It may seem a refinement to subdivide and sort cases of a disorder which is acknowledged to be only a symptom, or, as it has been expressed, a neural incident of cardio-vascular disease; but there are practical advantages which far outweigh any theoretical objections—advantages of the very greatest moment in prognosis and in treatment.

Following the work of Heberden, Parry, and others, there were cases reported as angina which did not belong properly to that category, and the disorder was confounded with cardiac asthma, which we now term cardiac dyspnoea. As early as 1812 J. Latham read a paper on certain symptoms usually but not always denoting angina pectoris (*Medical Transactions*, Royal College of Physicians). He remarks that when the extremities are cold, the countenance is bluish or purplish, the pulse is rapid, and respiration is performed with difficulty and in an upright position of the body, the practitioner has usually concluded that the disease is angina pectoris. The class of cases which he described were evidently orthopnoea and cardiac dyspnoea, associated chiefly with affections of the abdomen. He calls the state angina notha, spurious angina, the first time, so far as I am aware, that the term was used in literature.

Laennec recognized different degrees of intensity in

angina, stating that it was "far from possessing the degree of severity attributed to it by many authors," and was evidently aware that it occurred commonly enough without indicating any serious disease of the heart or large vessels. "Angina pectoris, in a slight or middling degree, is extremely common, and exists very frequently in persons who have no organic affection of the heart or large vessels." \*

By far the most important contribution to the recognition of varieties of angina pectoris was made by Walshe, who, in his text-book on *Diseases of the Heart*, described a pseudo-angina pectoris, occurring particularly in women, and in the subjects of hysteria, spinal irritation, and various forms of neuralgia.

The recognition by Beau, Graves, Stokes, and others of the relation between the abuse of tobacco and attacks of angina led to the separation of the important group of toxic cases. Other forms of pseudo-angina which are described are those dependent upon reflex causes, and the vasomotor type of Nothnagel.

In any long series, the cases of angina fall into two groups: those in which there are signs of lesion of the heart or arteries, or of both, and those in which all symptoms of organic disease are absent. This was the important division recognized by Forbes into organic and functional angina—the angina pectoris vera and the angina pectoris notha—the true and the pseudo-angina.

In looking over the cases which form the basis of these lectures, I find that they fall into the following groups: (1) Angina pectoris vera, and (2) angina pectoris notha, under which are grouped hysterical, vasomotor, and toxic forms.

THE CORONARY ARTERIES.—A few essential points in the anatomy and physiology of the heart may here engage our attention for a few minutes. The coronary arteries are the Abana and Pharpar of the vascular rivers, "lucid streams," which water the very citadel of life. By means of these injected specimens which I pass around, you may refresh your memories on their distribution. The arteries are, as you see, large in proportion to the size of the organ to be nourished. From the position of their origin it is evident that they must be subject to blood pressure during both systole and diastole. The left coronary is usually the larger, and divides into two main branches: the circumflex or posterior, which runs in the groove between the left ventricle and auricle, and the anterior or descending ramus. Note particularly the branches of the latter vessel, which runs in the anterior interventricular groove. You will see a very large branch, which is given off to the anterior wall of the left ventricle, and several branches which pass deeply into the septum. This anterior branch is the important one in the morbid anatomy of the coronary arteries, since it is by far the most frequently found the seat of exten-

sive sclerosis or of embolism or thrombosis. It may be called the artery of sudden death.

From the date of Sir John Eric Erichsen's observations on the subject (1812) to the present the effects of closure of the coronary arteries have been much discussed. A very good historical summary is given by W. T. Porter in the *Journal of Physiology*, vol. xv, 1893. It is remarkable how discordant are the statements of different observers. As this author remarks, seldom have the results of physiological studies been more at variance; there is no statement which is not denied, no fact which is not disputed. More recently Porter has again gone over the whole question with a great deal of skill, and I will give you here some of his conclusions.\*

The frequency of the stoppage of the heart's action is in proportion to the size of the artery tied. Ligation of the smallest artery, the arteria septi, does not cause arrest; of the next in size, the coronaria dextra, fourteen per cent. of the ligations were followed by arrest; then comes the larger descendens with twenty-eight per cent.; and, finally, the circumflex, the largest artery of all, with sixty-four per cent.

The effect of closure of the coronary arteries on the blood pressure within the heart is of great importance. After the tying of a single vessel there is a diastolic rise of pressure, which is not compensated for by any increase of pressure in the coronary arteries; on the contrary, in them the pressure is falling, while that in the auricles is rising. It is known that the normal mean pressure in the auricles, and consequently in the coronary veins near their mouths, is very low. A rise of a few millimetres of auricular pressure might interrupt the entire coronary circulation. This is one of the most important points brought out by Porter's researches, and I quote here a paragraph on this point: "It must be acknowledged, then, that a rising auricular pressure after ligation may at length put a stop to the whole blood supply of the cardiac muscle, and, as this rise is often occasioned by the closure of a single vessel, it is plain that the entire coronary circulation can, in fact, be interrupted by the ligation of one coronary artery."

It has been much debated whether the coronary arteries are really terminal or end arteries. Anatomically, it may be shown that they are not, since an injection liquid can be made to pass from one artery through communicating branches into the other. All are agreed, however, that the anastomosis is not sufficient to permit collateral circulation to keep a vascular area alive after the distributing artery is blocked. The effect of plugging of the artery is the production of what is known as an anemic infarct, a well-recognized pathological condition, the consideration of which need not detain us. A very important matter relates to the effect of plugging of the coronary arteries upon the heart-beat; the contractions become of the type known as fibrillary, and it is difficult

\* Forbes's edition of *Lectures*, fourth edition, p. 650.

\* *Journal of Experimental Medicine*, vol. i, No. 1, 1896.

or impossible to get the organ to resume the ordinary co-ordinated beats, though experimentally this has been done, even after fibrillary contraction has been established.

The relation of coronary-artery disease to angina pectoris, which was suggested by Jenner, has directed the very particular attention of writers to the changes in these vessels. It does one good to look over the older literature, and to note the accuracy with which some of the cases have been recorded, particularly by Morgagni. Parry, too, gives an interesting series from the older writers. The subject is so extensive that I can not enter upon it here in great detail, but I may, perhaps, bring it before you with sufficient emphasis if I speak of the common sequences in connection with illustrative cases.

The coronary arteries are very subject to degenerative changes, particularly in persons who have passed the middle period of life. They may be affected alone or as part of a widespread disease of the vessels. For practical purposes we need not consider any other change than arteriosclerosis in its various grades, from a trifling thickening to atheroma and rigid calcification. We must, however, recognize an affection of the orifices of the arteries, apart from the common degeneration of the trunks. A gradual narrowing of the orifice of a vessel may be quite as serious as extensive disease of the branches. There is a form of aortitis met with not infrequently in men between the ages of thirty and forty, who have had syphilis and who have worked hard and drank deep (*devotees of Venus, Bacchus, and Vulcan*), in which the intima is swollen, almost corrugated, with fresh translucent areas of endarteritis. I skip all considerations of its anatomy. Three serious sequences may follow: (a) Rupture of the aorta, sometimes only of the intima, as clean cut as with a razor, in half or a third of the circumference, sometimes with the formation of a dissecting aneurysm; (b) the slow development of the ordinary form of aneurysm of the arch; and (c) narrowing of the orifices of the coronary arteries. Angina attacks, sudden death, and slowly developing myocarditis and its sequences are the possibilities in this third category. I pass around this fine plate of Corrigan's, taken from the *Dublin Journal*, in which you see great swelling of the intima above the valves, due, as Corrigan expressed it, "to an effusion of organized lymph between the lining membrane and the fibrous coat." The patient in this case, a man only thirty-nine years of age, suffered with severe attacks of angina.

Let me illustrate by these specimens some of the more common pathological conditions associated with disease of the branches of the artery. Here is an extraordinary heart, which illustrates how much of the coronary circulation can be cut off if the obstruction takes place gradually. The organ was taken from a man aged about thirty-six or thirty-seven, who had been an inmate for eighteen years of the Institution for

Feeble-minded Children at Elwyn, Pa. He was a large, powerful imbecile, dumb but not deaf. He was very good tempered, did a great deal of work about the farm, and frequently did very heavy lifting. He never had epilepsy; he was not known to be short of breath, nor had he complained or indicated in any way that he was out of health. One afternoon he had a sort of fit, the face became very much congested, and he died in about half an hour. There was nothing special found in the brain. The heart, as you see, is large, and weighed twenty ounces. There was general hypertrophy with dilatation. There was quite extensive fibroid myocarditis, particularly in the anterior wall of the left ventricle, at the apex, and in the lower portion of the septum ventriculorum; the valves were normal. But what I wish you to examine most particularly is the state of the coronary arteries, which are freely dissected out. The left vessel is almost obliterated, only a pin-point channel remaining, while of the right artery the main division passing between the auricle and ventricle is converted into a fibroid cord!

It is much more common to find one artery extensively diseased, or even completely obliterated. Take, for example, this specimen, which was removed from a colored man, aged about thirty-five, who had aortic insufficiency, with dyspnoea and oedema of the legs. He died suddenly, though he had for some weeks great dilatation of the heart and general anasarca. The aortic segments are curled and thickened; the ascending arch is greatly deformed, with a recent general endarteritis. There are a few calcareous plates. The right coronary artery is completely obliterated. There is no opening whatever on the aorta. The left vessel is dilated, and presents atheromatous patches. There are areas of fibrous myocarditis in the left ventricle, but in other respects the muscular substance of the heart does not look abnormal, and it is not fatty.

Here is a much more common condition. In this anterior coronary artery you see a firmly adherent thrombus, which completely occludes the descending branch, to the lumen of which it is firmly attached. It was taken from a man about fifty years of age, who had mitral-valve disease and had a good deal of cardiac dyspnoea. Early one morning he was seized with severe pain about the heart and shortness of breath, and died in a very few moments. Both coronary arteries were thickened and calcified, and presented atheromatous plates, but no doubt the sudden death was due to the blocking of the anterior branch of the left coronary artery by the thrombus.

When the occlusion has persisted for any length of time before death the condition of anæmic necrosis may be found. I am sorry I have no fresh specimen to show you, but most of you have, no doubt, seen microscopic, if not macroscopic, examples. It is important in the dissection of the heart to slice carefully the septum and the wall, as these infarcts of the heart muscle are

found in numbers directly proportionate to the care with which they are sought. We have not had any very large number of cases. They are much more common, I think, in hospitals with old chronic cases, or with which there are in connection large almshouses, as at the Blockley Hospital. I was much impressed at that institution with the number of cases of anæmic infarcts—many more than I saw at the Montreal General Hospital or have seen here. They occur most frequently in the walls of the left ventricle and in the septum, particularly toward the apex. When fresh they stand out beyond the level of the surrounding muscle, and are sometimes very firm, yellowish white, or even quite opaque white in color. With the fresh infarcts there may be old fibroid patches, into which ultimately these areas of anæmic necrosis are transformed.

To complete the series, I show you here sections of the descending branch of the left coronary artery, which you see is almost completely obliterated by an old, much-altered thrombus. This case illustrates another sequence of slowly developing coronary artery disease—namely, fibroid, myocarditis at the apex, with weakening of the wall, and the gradual formation of aneurysm of the heart. The specimen was taken from the body of a large, powerfully built man whose heart symptoms developed with great abruptness, and who presented for many months an obscure train of symptoms pointing to serious disease of the myocardium.

Autopsies on cases of angina pectoris are not common. The man with a fresh thrombus in the anterior branch of the left coronary artery probably died in a paroxysm of angina, but he had not had previous typical attacks. As I will tell you later on, the disease is so rare in hospital practice that we do not have opportunities of making the inspection of the bodies of persons who have died of the disease.

And, lastly, a few words on the *innervation of the heart*, a cardinal point, inasmuch as the very essence of the angina paroxysm must rest on some profound disturbance in the function of the nerves. The newer methods of investigation have added considerably to our knowledge of the distribution of the intrinsic nerves of the organ. Doubtless some of you have seen in the pathological laboratory Dr. Berkeley's wonderful specimens illustrating the ultimate terminations of the filaments between and on the fibres.\* In looking at them one realizes the truth of the remark of a recent author, that it is difficult to say in which the myocardium is richer, in nerve elements or in muscle fibres. Everywhere throughout the organ—in the tissues beneath the endocardium and pericardium, throughout the muscle substance, and about the blood-vessels—the nerves are in extraordinary profusion. The double nerve supply you know, from vagus and sympathetic, and the double function, the former controlling, checking, and inhibiting,

the latter augmenting the force and hastening the frequency of the heart-beats. The researches of His junior and Romberg have shown that the ganglion cells of the heart, even those lying in the vagus branches, have the same origin as all other sympathetic cells. They differ in protoplasmic appearances and in other ways from the cells of the spinal ganglia. The rhythmic action of the heart is probably automatic, due to a power inherent in the muscular fibres, though this point is still in dispute. Of the functions of the nerves we know a good deal, of the functions of the ganglia nothing. His and Romberg suggest that from them are transmitted to the central nervous system infinitely delicately graded, unconscious impulses, which regulate the circulation reflexly through the vagus and accelerator. Of Kronecker's co-ordination centre our knowledge is still very indefinite—in deed, its existence has been called in question. I have seen Kronecker perform the experiment, and certainly when the point in the dog's heart is pricked—it is situated about the lower limit of the upper third of the ventricular septum—the organ becomes paralyzed in a state of fibrillary tremor, from which it does not recover. This point is within the area of distribution of the anterior coronary artery, the vessel oftenest found plugged by thrombus or embolus in cases of sudden death in man.

Do these cardiac nerves possess other properties? Have they also, with the special function, the endowment of receiving tactile and painful impressions? Certainly the heart is not an organ of very acute sensibility. The most extensive lesions, inflammatory, degenerative, and neoplastic, may not excite a single painful sensation. Pericarditis of the most intense grade, with deep involvement of the myocardium, may give not the slightest indication of its existence.

In experimental work, pinching of the heart muscle may excite reflex movements of the muscles of the body. There are a few interesting cases in the human subject in which the heart has been exposed by accident sufficiently to enable it to be grasped or touched. In the well-known case which Harvey gives\* of the young Viscount de Montgomery, in whom Charles I was so much interested, in consequence of a fracture of the ribs on the left side, with excessive suppuration, the heart was exposed, and from Harvey's account was quite insensitive: "Nempe, in homine vivente et vegeto, citra ullam offensam, cor sese vibrans, ventriculosque ejus pulsantes videret, ac manu tangeret. Factumque est, ut serenissimus Rex, una mecum, cor sensu tactus privatum esse agnosceret. Quippe adolescens, nos ipsum tangere (nisi visu, aut cutis exterioris sensatione) neutiquam intelligebat."

There is one other point of great importance. Sensory-nerve endings have been demonstrated in the arteries by Thoma, and recently Snirnow† professes to have

\* Described in *Johns Hopkins Hospital Reports*, vol. iv.

\* *Exercitationes de generatione animalium*, 1651, p. 311.

† *Anatomischer Anzeiger*, 1895.

demonstrated similar structures in the connective tissues of the heart, he thinks the sensory-nerve beginnings of the depressor nerve.

### Original Communications.

## THE DIFFERENTIAL DIAGNOSIS BETWEEN BENIGN LYMPHOMYXOMA AND MALIGNANT LYMPHOMYELOMA.\*

By JOHN A. BEUERMANN, M.D.

ANY one having examined a large number of tumors of the type of lymph tissue will admit that the differential diagnosis between benign and malignant forms is extremely difficult, especially without the knowledge of the clinical history. Virchow† speaks of a benign lymphoma, which he considers merely a hyperplasia of

lymph tissue, such as we meet with in mucous membranes, especially in children and young adults, are rather prone to proliferate and produce what rhinologists like to call "adenoids." On the other hand, we know

FIG. 2.—Lymphomyxoma (so-called "adenoid") of the turbinated bone, magnified 1,200. S.S. Small, solid lymph corpuscles. V.V. Vacuolated lymph corpuscles. R.R. Reticulated lymph corpuscles. B.B. Faintly reticulated basis substance. M.M. Myxomatous reticulum of lymph tissue. C. Capillary blood-vessel.

that in almost any organ of the body tumors called by Virchow small round-celled sarcoma, being of the type of lymph tissue, may arise. They are of rapid growth and considerable malignity, and have often no apparent connection with any normal lymph tissue.

I am convinced that on the ground of cellular pathology we shall never reach the solution of the puzzle

FIG. 1.—Lymphomyxoma (so-called "adenoid") of the turbinated bone, magnified 300. E.E. Epithelial layer. F.F. Myxo-fibrous layer surrounding the epithelial layer. L.L. Lymph tissue. C.C. Wide capillary blood-vessels.

lymph tissue, and a lymphosarcoma, which latter is characterized by the lack of persistence of its elements and the progressive and, at times, very acute growth of the tumor. He applies both these terms only to growths from the lymph ganglia, erroneously termed "lymph glands." To-day we know, however, that layers of

FIG. 3.—Lymphomyeloma of the testis, magnified 240. B.B. Bundles of fibrous connective tissue of the albuginea, much reduced in bulk. C.C. Myeloma elements, spring from previous fibrous connective tissue. L.L. Tissue of lymphomyeloma.

why a tumor of the structure of lymph tissue should at times be benign and at other times malignant. A solution of this puzzle seems possible only if we admit that the so-called protoplasm is traversed by a reticulum the points of intersection of which, previously termed granules, may grow out into solid lumps of living matter, which in further development become vacuolated, afterward reticulated, and at last transformed into nucleated protoplasmic bodies. Another point which will aid us

\* Read before the German Medical Society of the City of New York at its meeting, June 1, 1896.

† *Die krankhaften Geschwülste*. Berlin, 1864 and 1865.

in distinguishing between benign and malignant growth of lymph tissue is the fact that the basis substance of connective-tissue varieties is traversed by a reticulum of living matter being transformed into protoplasm. Normal lymph tissue, both of the lymph ganglia and the diffuse layers of the mucous membranes, is myxomatous tissue—i. e., a delicate, so-called stellate reticulum, holding in its meshes a certain amount of a soft, jellylike myxomatous basis substance and a varying number of lymph corpuscles. That such a stellate reticulum does exist in the lymph tissue all histologists now admit; but that this tissue is of the myxomatous variety is not as yet generally acknowledged. I do not hesitate to term what Virchow has called small round-celled sarcoma a lymphosarcoma, or preferably lymphomyeloma. Virchow's name sarcoma means a fleshy tumor, and does not truly designate a malignant tumor bearing all the

contain several lymph corpuscles, up to six in number. In some places, always of a limited extent, the lymph corpuscles are more crowded and the myxomatous reticulum less pronounced. These are obviously places where

a more lively outgrowth of the living matter and the tumor is taking place, resulting in a temporary increase of the bulk of the whole tumor. I would lay stress upon the fact that the myxomatous reticulum is always traceable; certainly with less ease and distinctness in places where the lymph corpuscles form crowded masses than in the spot from which this drawing is taken.

The amount of blood-vessels is not to be considered typical for this kind of tumor; our case shows rather a goodly number of capillaries.

characteristics of an embryonal or medullary tissue. The word myeloma, as suggested by Dr. Carl Heitzmann, would readily indicate a tumor of the embryonal or medullary type.

Let us analyze with medium power of the microscope a so-called adenoid growth sprung from the mucosa covering the turbinated bone (see Fig. 1).

We perceive epithelial formations surrounded by a myxo-fibrous tissue, rather rich in small globular or oblong, non-nucleated elements. The main mass of the growth consists of lymph tissue—i. e., a protoplasmic reticulum, the meshes of which contain an indistinctly granulated basis substance and a number of so-called lymph corpuscles, formations of living matter, varying in size from a small homogeneous lump to a granular corpuscle, in which we recognize but exceptionally a distinct nucleus. The reticulum is mostly protoplasmic, but in many places fibrous, infiltrated with a glue yielding basis substance, and here and there even broader tracts or bundles of fibrous connective tissue are met with traversing the lymph tissue. Most of the meshes

FIG. 6.—Lymphomyeloma-sarcoma of the tonsil, magnified 100. E.E. Stratified epithelial layer. V. Vesicle filled with an albuminous liquid within the epithelial layer. M. Nest of myeloma, penetrating the epithelial layer. C.C. Connective tissue capsule crowded with lymph corpuscles. L.L. Lymphomyeloma, with scanty tracts of fibrous connective tissue.

If viewed with a high power, such a tumor, for which I would suggest the name of lymphomyxoma, presents features quite characteristic, as shown in Fig. 2.

Here we see a myxomatous reticulum, well pronounced, exhibiting broadened points of intersection,

with interspersed nuclei in the broadened places. The meshes hold a myxomatous or mucoid basis substance, in which we have no difficulty in recognizing the extremely delicate reticulum of living matter, without taking recourse to any reagent whatever. In the basis substance we recognize small, glossy, and homogeneous lumps in a rather moderate number; then somewhat larger lumps, with a varying number of vacuoles in their interior; at last the larger lymph corpuscles, showing a distinct reticulum of living matter in their interior. Nucleated protoplasmic bodies, such as are seen even in normal lymph ganglia, especially in the centres of the follicles, are not present in the spot chosen for illustration, and are, indeed, scanty throughout the tumor under consideration. Whatever the size of these corpuscles be, they invariably show radiating spokes of living matter which enter into and inosculate with the reticulum of the basis substance.

The malignant lymphomyeloma (small, round-celled sarcoma of Virchow) presents to us quite a different aspect. Fig. 3 illustrates a section from one of these tumors of the testis. We not infrequently meet, in a malignant growth of this description, with an extremely delicate myxomatous reticulum, the meshes of which appear crowded with lymph corpuscles; in the spot I have selected here, however, such a myxomatous reticulum is entirely absent.

In the main mass of the tumor we fail to recognize any variety of basis substance, but it presents a mass of so-called coarsely granular protoplasm, in which we find imbedded, without any apparent regularity, a large number of elements which, owing to their size and shape, no microscopist could distinguish from lymph corpuscles. The number of somewhat larger coarsely granular protoplasmic bodies is far greater than in benign lymphomyxoma; the number of still larger nucleated protoplasmic bodies is quite conspicuous—so much so that the tissue here and there approaches the type of globomyeloma (large round-celled sarcoma of Virchow). In analyzing this tumor, we find larger masses composed of nucleated protoplasmic bodies; therefore we have a combination of lymphomyeloma and globomyeloma, as may be, indeed, observed in a majority of myeloma tumors of a pronouncedly malignant type.

Similar features are found in an extremely malignant lymphomyeloma of the thyroid body, which shows vestiges of previous walls and alveoli (Fig. 4).

High powers of this tumor plainly exhibit the typical features of an intensely malignant and rapidly growing lymphomyeloma (see Fig. 5).

A few tracts traverse the myeloma tissue, being in so-called hyaloid degeneration and not exhibiting any distinct structure. In the myeloma tissue itself we notice numerous comparatively large points of intersection of the living matter, evidently the starting-point for the formation of lymph corpuscles. We can trace all stages, from a minute granule to a distinct glossy lump,

not showing any structure as yet. The large number of such lumps is certainly indicative of rapid growth, and therefore of considerable malignancy of the tumor. After the lumps have gone through the process of vacuolation, they assume that of reticulation, and then these bodies are in the condition termed by the older pathologists "coarsely granular." In our present views this so-called coarse granulation signifies a considerable increase of living matter, even in the stage of reticulation of lymph corpuscles. A good many protoplasmic bodies in the reticular stage exhibit central lumps of living matter, generally termed nuclei. Even these nuclei show stages of development from a solid homogeneous to a vacuolated and at last reticulated lump of living matter.

The second point that I would consider of great value for the distinction between a benign lymphomyxoma and a malignant lymphomyeloma is the condition of the fibrous connective tissue, either surrounding the invaded organ in the shape of a capsule, or traversing the same in the shape of trabeculae in alveolar structure, or as interstitial tissue in glandular organs. Whereas in benign lymphomyxoma the capsule surrounding the tumor remains unchanged and always well pronounced, in malignant lymphomyeloma the amount of fibrous connective tissue is invariably reduced in a considerable degree. In Fig. 3 we see the albuginea of the testis in this condition. In analyzing such fields we easily reach the conclusion that the fibrous connective tissue is transformed into the tissue of the myeloma. While the myeloma tissue increases, the amount of fibrous connective tissue steadily decreases in bulk; in other words, the myeloma grows at the expense of the fibrous connective tissue. With higher powers of the microscope we can satisfy ourselves that it is not only the tracts of protoplasm between the bundles which give issue to the myeloma, but the bundles themselves, respectively their basis substance, likewise are transformed into myeloma through the intervening stage of a transformation of this basis substance into protoplasm, from which it had arisen. This fact is not surprising to the microscopist, who is aware of the fact that the fibrous, as indeed any other variety of connective-tissue basis substance, is traversed by a large amount of living matter in reticular arrangement. Thus nothing is required but a liquefaction of the glue-yielding substance in order to re-establish its protoplasmic condition. In Fig. 4 tracts of fibrous connective tissue are seen traversing the myeloma tissue, partly in a hyaloid degeneration, therefore not exhibiting everywhere a plainly fibrous structure. The tracts in many places gradually blend with the myeloma tissue, or are pierced by rows of protoplasmic bodies, plainly indicating the manner in which the fibrous connective tissue perishes as such, and is transformed into myeloma tissue. This process can be still easier traced with high powers of the microscope, under which many of these tracts appear partly transformed into, at first, the so-called finely granular, and

later into a coarsely granular protoplasm, which directly gives issue to the so-called lymph corpuscles by the growth or development of the points of intersection of the living matter. The observation of this transformation of the capsule of the lymph ganglion, called tonsil, is of especial value (Fig. 6).

Whenever a rapid growth takes place in the tonsil, the question comes up whether this growth is due to a merely hyperplastic or inflammatory process, which would be benign, or to a malignant growth known to endanger the life of the patient. In the former instance the follicles are invariably preserved, and the capsule environing the tonsil is always plain, representing a more or less broad layer of fibrous connective tissue, bordering the lymph structure toward the epithelial cover. As soon as the lymph tissue has assumed the malignant type of lymphomyeloma the follicles perish, since the boundary line is lost to sight and the enveloping capsule is much reduced in bulk by being crowded with lymph corpuscles. These two features are sufficient, in my opinion, to establish the diagnosis of a malignant lymphomyeloma of the tonsil, which, fortunately, is of rare occurrence.

The third typical point for the distinction between a benign lymphomyxoma and a malignant lymphomyeloma is the behavior of the epithelial structures, either covering the surface of the tumor or being present in the shape of acinous or tubular glands in the lymph tissue of the mucous membranes. Fig. 1 illustrates an epithelial layer sharply bordered by myxofibrous tissue toward the myxomatous lymph tissue of the tumor. This means that the growth of lymph tissue will never affect or destroy the epithelia. This is quite different with malignant lymphomyeloma, which invariably will transform either the cuboidal epithelia of acinous glands or the columnar epithelia of the tubular ones into myeloma. Rapidly growing lymphomyeloma will by degrees completely destroy and transform into its own type all epithelial formations of glands. In Fig. 3 a portion of a malignant myeloma of the testis of the size of a man's fist is illustrated, nowhere exhibiting even the slightest trace of previous seminiferous tubules. The same is the case with the lymphomyeloma of the thyroid body, drawn in Figs. 4 and 5, in which all epithelial structures have been destroyed. In Fig. 6 the stratified epithelium covering the tonsil is pierced by a globular field of lymphomyeloma, obviously originating from transformation of originally epithelial into myelomatous tissue. The spot where the invasion of the latter tissue was effected is plainly seen in the drawing. To the right of the myeloma nest may be seen a follicle, filled with albuminous liquid, such as are frequently seen in the aural epithelium. To the left of this follicle the stratified epithelium was found almost completely destroyed and transformed into the tissue of myeloma to a considerable extent.

I have abstained from illustrating the transformation

of epithelial into myelomatous tissue, since there exists quite a literature on this topic, with numerous illustrations. I refer to the essays of Dr. Rudolf Tauszki,\* Dr. Louis Heitzmann,† and Dr. Charles Dixon Jones.‡

What I have stated in this paper has reference solely to the microscopic features of the tumors under consideration. Fortunately, the clinician is often enabled to establish a diagnosis from the clinical features and the history of the case. Neither microscopists nor clinicians, however, should consider themselves infallible; in doubtful cases, unquestionably, the microscope should be called upon to determine the intimate nature of a tumor of the type described.

1891 LEXINGTON AVENUE.

### REPORT OF FIVE CASES OF UTERINE RETRODISPLACEMENT TREATED BY VAGINAL FIXATION (MACKENRODT).\*

By FREDERICK HOLME WIGGIN, M.D.,  
VISITING GYNECOLOGIST TO THE NEW YORK CITY HOSPITAL,  
AND SURGEON TO ST. ELIZABETH'S HOSPITAL.

DURING the last few years, differences of opinion have been so great as to the proper method of treating retrodisplacements of the uterus which give rise to symptoms, by operative measures, that reports of cases, especially those treated by the more recent procedures, are of interest, and will be useful in helping us to form an opinion as to the best method for relieving this, at times, annoying local trouble.

VAGINO-FIXATION, FOLLOWED BY CURETTAGE, OOPHORECTOMY, AND APPENDICITIS.—B. S., a married woman, twenty-seven years of age, was admitted to the gynecological ward of the City Hospital, November 22, 1895. She stated that her first menstrual period occurred during her fifteenth year, that the menstrual flow was regular, of the tri-weekly type, and that it was preceded by pain located in the lower abdominal region. Eight years ago she had had a child, the labor being normal in all respects. Five months prior to admission, her last menstrual flow had occurred, and since that time she had suffered from metrorrhagia. Vaginal examination revealed an enlarged, hard, tender, and retroplaced uterus, accompanied by an enlarged and tender ovary on its right side. The case was diagnosed as one of "chronic endometritis, retrodisplaced uterus, and small ovarian cyst." On December 2d, after the usual preparation of the patient, and under ether narcosis, she was re-examined vaginally, and as the right ovary felt smaller than

when the previous examination was made, it was decided not to open the peritoneal cavity, but to perform curettage and vaginofixation of the uterus, after it had been anteverted, according to the method devised by Mackenrodt, of Berlin. These procedures having been carried out in the usual manner, excepting for the fact that no gauze was placed in the uterine cavity, the convalescence was uneventful, and the patient left the hospital with the uterus in good position on December 30th.

On January 5, 1896, the patient was re-admitted to the gynecological service of the hospital, complaining of much pain in her right side. On January 13th, after the usual preparation of the patient, and under ether narcosis, the abdominal cavity was opened by an incision to the left of the median line, splitting the rectus muscles of that side and incising the other tissues. The uterus was found to be well anteverted and adherent. Several small cysts were found in the left ovary. These were excised, and the resulting wounds were sutured with fine silk. The right ovary contained a larger cyst, and as there appeared to be no normal ovarian tissue, it was removed after the peritoneal cavity had been freely irrigated with normal saline solution. The wound in the abdominal wall was closed by a single row of silkworm-gut sutures, which were passed through all the layers of tissue.

On January 22d the patient's bodily temperature rose to 103° F., and she complained of severe abdominal pain in her right inguinal region, radiating down her right thigh. Vaginal examination at this time proved negative. As the symptoms continued with unabated severity, on January 23d, under ether narcosis, the pelvic cavity was opened by an incision in the posterior vaginal wall, and the region explored with the finger. Palpation revealed the fact that there were no adhesions about the left ovary, but that high up on the right side some adhesions existed. Those within reach were broken up, but no pus escaped. After free irrigation, a piece of iodoform gauze was placed in the pelvic cavity for the purpose of effecting drainage should the abscess rupture in this direction. On January 24th, the vaginal packing and pelvic gauze were removed, but there was no discharge of a purulent character. The patient's temperature was 104°, and she complained of severe, lancinating pain in the right inguinal region. On January 25th, the patient's condition was unchanged. She was prepared and placed under ether narcosis, and the abdominal wall was incised. In this way a large abscess was reached and evacuated. It seemed probable that it was of appendiceal origin, as at the time of the oophorectomy the appendix was adherent, but as it did not appear to be much injured, on examination, it was not removed. The further convalescence was uneventful.

Lizzie S., a single woman, twenty-three years of age, was admitted to the gynecological service at the City Hospital, January 22, 1896. She stated that her first menstrual period occurred during her thirteenth year; that it had been irregular and painful. She had had one child, one year prior to admission. The labor had been severe, and had been followed by some hemorrhage, fever, abdominal pain, and a vaginal discharge, which had continued. Vaginal examination revealed the facts that the uterus was somewhat enlarged, that it was movable, but that it was posterior.

On January 27th, after proper preparation of the patient, and under ether narcosis, the cervix was dilated, and the uterine cavity curetted and irrigated with a 1-to-4,000 bichloride solution. The anterior vaginal wall was

next incised, and after the bladder had been separated from the uterus the fundus was caught by bullet forceps, drawn forward, and fastened to the vaginal flaps by means of two heavy catgut sutures. The vaginal wound was closed with the aid of interrupted catgut sutures. The patient's convalescence has been uneventful, her bodily temperature hardly rising above normal. The menstrual flow was re-established on February 22d; it was painless, and of four days' duration. In March it was noted that the uterus had remained in good anterior position.

S. C., a single woman, was admitted to the gynecological ward of the City Hospital on December 10, 1895. She stated that her first menstrual period occurred during her ninth year, and that the menstrual flow had been regular and of the monthly type until recently. It had always been accompanied by pain in the sides and back. Eight months ago she had had a child, and since that time her health had been poor, as she had suffered from menorrhagia and metrorrhagia. Vaginal examination revealed an enlarged, tender, and retroplaced uterus. On December 14th, after the patient had been prepared in the usual manner and under ether narcosis, the cervix was dilated and a curettage performed. After this, Mackenrodt's operation was performed. The patient's convalescence was uneventful.

On December 30th, as she complained of pain in her lower abdomen, an exploratory laparotomy was performed. The position of the uterus was satisfactory. The appendages were somewhat adherent, but were otherwise normal. After the adhesions had been broken up, and the peritoneal cavity had been freely irrigated with hot saline solution, the abdominal wound was closed by a single row of silkworm-gut sutures passing through all the different layers of tissue. The wound healed primarily, and the convalescence was uneventful. On January 22d the patient was allowed to leave her bed. On January 29th it was recorded that on vaginal examination the uterus was found to be anterior, and that the patient had stated that her pain had disappeared.

M. G., a widow, thirty-two years of age, was admitted on November 14, 1895, to the gynecological ward of the City Hospital. She stated that her first menstrual period occurred during her fourteenth year; that menstruation had been regular and of the monthly type, but painful before the flow was established, and that this pain was felt in the lower abdomen and small of the back. Her last menstrual period had occurred on November 1st, and since that time she had been suffering from metrorrhagia. She also stated that three years ago she had undergone a laparotomy for the removal of an ovarian cyst, and that this had been accompanied by an attack of cystitis. Three months prior to admission to the hospital she had undergone a curettage and a trachelorrhaphy. Vaginal examination revealed the fact that the patient had a large protococele, that stenosis of the external os existed, and that the uterus was retro-displaced.

On November 22, 1895, after the patient had been prepared in the usual manner, and had been placed under ether narcosis, the cervix was drawn down, and after a probe had been passed into the cervical canal the latter was incised and dilated. The uterine cavity was then curetted, and after irrigation an Outerbridge dilator was introduced into, and left in the cervical canal. After this, the anterior vaginal wall was incised, the bladder separated, the uterus anteverted, and attached to the anterior vaginal wall, according to the method of Mack-

enrodt, of Berlin. The peritoneal cavity was not opened. The patient's convalescence was uneventful, excepting for the fact that the necessary catheterism lighted up the chronic vesical inflammation which had existed for some years prior to the last operation. This made it necessary to wash out the bladder with a boric-acid solution. On December 11th it was noted that the wound of the anterior vaginal wall was healed excepting at one small point, and that the uterus was anteverted and adherent. On December 20th the cervical dilator was removed, the canal being well opened. On January 29th it was found that the position of the uterus was satisfactory.

S. S., a single woman, eighteen years of age, was admitted to the gynecological ward of the City Hospital on December 12th, 1895. She stated that her first menstrual period occurred during her eleventh year, that menstruation had been more or less irregular, and that it had been accompanied by pain before, during, and after the flow had been established. She had had no children, but in May, 1894, she had had a miscarriage at two months, which had been followed by a long illness of a feverish nature, and by severe pain in the lower abdominal region. This pain had been rather more severe on her left side, and had radiated into the small of the back and down both thighs. It had been increased by the upright position or by walking. She also stated that she had had syphilis, the first symptom of which had appeared during June, 1894, and that in March, 1895, she had submitted to a curettage, which procedure had temporarily improved her condition. Vaginal examination revealed the fact that the uterus was enlarged, tender, and retroplaced, and that an enlargement of the right ovary existed.

On December 30th, after the usual preparation, and under ether narcosis, the anterior vaginal wall was incised, the bladder separated, the fundus of the uterus drawn forward, and the vesico-uterine fold of the peritonæum incised. On examination, the left ovary and tube proved to be normal, but the right ovary was found to contain a cyst, and this was removed. The uterus was then attached by three catgut sutures to the anterior vaginal flaps, which were united by a continuous suture of catgut. On January 4th there was a slight elevation of the patient's temperature, and she complained of colicky uterine pain. Vaginal examination revealed the fact that the uterine body was acutely flexed on the cervical portion, the sutures having been placed too low down on the body. Under chloroform anesthesia the sutures were removed and some of the adhesions broken up, and the uterus placed in a better position. It was found that these adhesions were already very strong. The patient progressed favorably until January 15th, when she was attacked by scarlet fever, and was removed to the Willard Parker Hospital.

In the cases herewith reported, with the exception of the fifth, the vesico-uterine fold of the peritonæum was not divided. The failure to do this necessitated the performance of a second operation at an early day in Case I. The writer believes that in all cases thought to require this operation, the vesico-uterine fold of the peritonæum should be divided, and the exact condition of the annexa determined by aid of sight as well as by touch. This addition to the original technic does not in any way increase the slight risk which the patient runs who is subjected to this procedure. The opposition to this

method of treating uterine retrodisplacements which has been encountered of late by Mackenrodt has, Dr. Vineberg believes, been due to the employment of faulty technics. In this view the writer concurs. Recently it has been stated in various journals that Mackenrodt has abandoned this procedure. In view of these reports, the writer communicated with Dr. H. F. Brownlee, of Danbury, Conn., who had recently visited Dr. Mackenrodt's clinic, and asked him to express his opinion as to the correctness of these statements. He has received the following reply:

MY DEAR DOCTOR: In reply to yours of yesterday, I have not seen the statement you refer to, and can hardly believe that it is reliable. I spent two months in Berlin last summer (June and July), and took a private course with him during that time, and became quite well acquainted with him. At that time he was thoroughly satisfied with his operation, but was making a strong fight against the method used by Dührssen, Olshausen, and others—i.e., the fixation of the fundus with silkwormgut. He makes a point that where only catgut is used, the uterus is held only by adhesions, and that these adhesions do not interfere with pregnancy, while a silkworm or any other non-absorbable suture is a serious danger if pregnancy takes place. He told me that in a great number of his cases the patients had borne children since operation with no trouble whatever.

He has said for a long time that trouble would arise from these permanent stitches, and a short time before my departure his prophecy was fulfilled in a case at the Charité, where a laparotomy was necessary to delivery. A Porro operation was done, I think by Gusserow, resulting fatally, and the case was exhibited at a subsequent meeting of the Berlin Gynecological Society.

I believe Mackenrodt to be a thoroughly honest man, and if he were convinced that his operation was wrong he would readily acknowledge it, but I do not believe the statement true, for I think it impossible for him to have made such a radical change after two years' experience, and being so well satisfied at such a recent period.

I have done two operations here; my first was all right, and the result so far good. It was done in October, 1895. My second was unfortunate through some faulty catgut, which gave way on the second day, allowing the fundus so much freedom that I did not get adhesions firm enough to hold, and in three months the fundus was again in the posterior *cul-de-sac*. I did the operation over again, four weeks ago, and used kangaroo-tendon sutures for the fundus (two). The result so far is good. Of course, both of these cases are too recent to form definite conclusions, and neither patient has become pregnant, so the cases are of no use to you.

The writer believes that if the process about to be described is adhered to, the results obtained will prove entirely satisfactory, and that the operation of vaginal fixation will, in time, be proved to be the most satisfactory means at our command for the permanent relief of those suffering from retrodisplaced uteri. The patient is prepared as for a vaginal hysterectomy, and is placed on the table in the dorsal position, with the thighs flexed and held in place by a Clover crutch. As in this class of cases there is more or less endometritis, it is well to begin the operation by curetting the uterus with a sharp

curette, gauze not being placed in the cavity. Any existing laceration of the cervix should be repaired, sutures of catgut being used. These steps having been taken, the cervix is grasped and drawn downward and forward by the aid of a bullet forceps. Then a portion of the anterior vaginal wall, about three quarters of an inch below the meatus urinarius, is taken up in the same way and drawn forward and upward, thus stretching the wall. An incision is made, beginning at the last-named point and continuing to the cervix. If this wall is more or less prolapsed, the incision, instead of being straight, should be oval, allowing for the removal of sufficient tissue to overcome this defect when the sutures which close the vaginal wound are placed. These flaps are dissected from the inferior surface of the bladder, into which a sound is passed, and by its aid the thickness of the bladder wall is estimated and its lower border defined. A needle, threaded with pedicle silk, is passed through the inferior edge of either flap and tied, the ends being kept long. These serve as retractors, and, the flaps being held aside, a curved transverse incision is made at the cervico-vesical junction. The bladder is freely separated from the uterus by blunt dissection with the finger, the vesico-uterine fold of peritonæum being divided by the aid of scissors. The patient's hips are elevated, which allows the bladder and intestines to gravitate from the uterus, the fundus of which is brought into view and is seized with a bullet forceps and drawn forward. The ovaries and tubes are inspected, after any existing adhesions have been broken up, and if diseased are removed. A suture of chromicized catgut or kangaroo tendon is passed by means of a curved Hagedorn needle through the left vaginal flap at a point slightly distant from its superior margin, then through the muscular tissue of the anterior uterine wall, close to the fundus, and then through the right vaginal flap near its upper margin. A second suture is passed in the same way, about one third of an inch below the first. The uterus being well anteverted, the sutures are tied loosely. The balance of the wound in the anterior vaginal wall, after free irrigation with saline solution and the application of hydrogen dioxide, if there is much oozing, is closed by means of interrupted sutures of horsehair, and the wound is sealed by painting it over with a ten-per-cent. solution of iodine in ether. A small quantity of gauze is placed in the vagina for the purpose of effecting drainage, and an antiseptic pad is applied to the vulva.

55 WEST THIRTY-SIXTH STREET.

**The Kentucky School of Medicine.**—We learn that we were in error in stating, in the last issue of the *Journal*, that the chairs occupied by Dr. W. H. Wathen and Dr. M. F. Coomes had been declared vacant. They are still occupied by those gentlemen. We are informed that at a recent meeting of the faculty the following appointments were made: Dr. Louis Frank, lecturer on clinical and operative gynecology; Dr. Henry E. Tuley, lecturer on obstetrics; Dr. Carl Weidner, lecturer on physiology; Dr. W. E. Grant, lecturer on anatomy; Dr. Ewing Marshall, lecturer on physical diagnosis; Dr. T. C. Evans, lecturer on ophthalmology, otology, and laryngology.

## OBSERVATIONS ON THE LOCAL USE OF HYDROCHLORIC ACID IN BONE NECROSIS OF TUBERCULOUS ORIGIN.

WITH A REPORT OF CASES.\*

By JEROME HILTON WATERMAN, M. D.

HAVING been invited to report my observations on the local use of hydrochloric acid in bone necrosis of tuberculous origin, I will present the results of a series of cases which I have recently treated by this method at the Hospital for the Ruptured and Crippled, New York.

There were in the hospital at this time several cases of necrosed bone of tuberculous origin which failed to respond to the usual method of treatment. In some of these the most radical operative means had been employed, the bone being thoroughly curetted and all the necrosed tissue supposed to have been removed. Sinuses subsequently formed, and an examination under an anæsthetic revealed the fact that necrotic bone was still present. In the other cases of the series, irrigation with solutions of bichloride of mercury, hydrogen peroxide, packing with various kinds of gauze, and the injection of creosote and protonuclein into the sinuses had been painstakingly employed for many months without favorable results, either in decreasing the amount of discharge or in allaying the progressive character of the pathological condition. Confronted with these unsatisfactory results, I resolved to try the application of hydrochloric acid. We find by experiment that the action of the acid on healthy bone is limited to the decomposition of the mineral constituents, consisting principally of phosphates and carbonates of calcium, together with small quantities of the alkaline salts; so far as we know, not affecting the animal matter. Since in necrosed bone we have only these mineral salts remaining, the chemical action of the acid is more particularly confined to the diseased part, dissolving it without exerting any destructive influence on the underlying tissue. In this fact lies one of the real merits of the treatment, for the diseased tissue being removed, the process of reparation can go on unobstructed.

Now, as to the method of employment: The acid was used in the concentrated form, whereas heretofore for the most part dilute solutions and solutions in combination with various substances have been used by other writers. The number of minims injected in each individual case depended, of course, on the amount of bone which was diseased and on the general condition of the patient. It is preferable not to use the acid more than twice a week, owing to the reaction and pain which might result. However, contrary to expectation, but little pain was experienced, and this I attribute in part to the fact that the patients were accustomed to more or less manipulation, having been dressed daily for several months, and also to the anæsthetic effect of the acid.

\* Read by invitation before the American Orthopaedic Association at its tenth annual congress, May, 1896.

In case it should produce undue discomfort, it is advisable to spray the tissues with a four-per-cent. solution of cocaine or cocaine and morphine a few minutes before injecting the acid; or I would suggest as an admirable substitute the chloride-of-ethyl spray. It was my custom to thoroughly wash out the sinus with sterilized water in order to remove any pus or detritus, and thus permit the acid to penetrate all of the diseased bony tissue.

The ordinary sterilized glass pipette was found to be the most practical means for the application of the acid. The tube was introduced to the bottom of the sinus and the contents deposited directly upon the necrosed structure. After this, I usually allowed a minute to elapse, then irrigated the sinus with a saturated solution of bicarbonate of sodium, and then applied a wet myrrh dressing. My object in using the latter in preference to dry dressings was because of the marked fetor noticed in many instances after the first two or three injections. This is accounted for by the destruction of soft tissues, and was more pronounced when the patient moved and the application was not made directly to the bone, but dropped partly on the surrounding tissues.

In certain cases of the series it was necessary to enlarge the opening during the course of treatment, particularly when the granulations were so exuberant as to protrude into the lumen of the sinus, but in the majority of instances they could be removed by the introduction of a probe.

Having described in a general way the method of application, it will be of interest to relate the existing conditions at the time the treatment was begun, as well as the final results attained.

CASE I.—V. B., aged ten years. Diagnosis: left hip disease, third stage. The patient was admitted into the hospital in July, 1894. In August, a large abscess on the antero-external part of the thigh opened spontaneously. Since that time the discharge has been profuse. In January, 1896, an examination showed the presence of a small amount of necrosed bone, and hydrochloric-acid applications were begun. There were two minims injected twice a week for the first five weeks and no improvement noticed; so I decided to increase the amount to six minims a week for the next three months, after which it was discontinued on account of the patient's general weakened condition. An examination last week, four and a half months after the inception of the treatment, showed that the sinus had so completely closed as to render it impossible to insert a probe into the opening.

CASE II.—M. S., aged thirteen years. Diagnosis: left hip disease, third stage. This child was admitted December 18, 1894. In August, 1895, a deep femoral abscess was detected and an excision of the hip was performed. Suppuration followed, and daily irrigation with various antiseptics producing no effect, the acid treatment was begun. The patient presented at this time an opening on the anterior aspect of the thigh and another leading to the ilium. Into both sinuses were injected four minims of the acid twice a week, receiving in all ten applications. During the course of the treat-

ment the dressings were so fetid that it was necessary to keep the patient apart from the others in the ward, but I do not attribute this to the acid alone, as the same condition existed to some extent prior to the treatment. The discharge was much less after the first six weeks, but at the present time the sinuses have shown no tendency to close.

CASE III.—W. B., aged eight years. Diagnosis: right hip disease, third stage. The child was admitted into the hospital in May, 1893. There being some fluctuation about the hip joint, the patient was aspirated, and later an incision was made in order to establish better drainage. In January, 1895, there were four sinuses around the joint, all discharging copiously. Since all efforts to heal them proved futile, in January, 1896, the patient began having injections of the acid. As the sinuses were thought to communicate, only the one on the anterior part of the thigh was injected, three minims twice a week being applied. The discharge decreased and the sinuses gradually became smaller, but the general condition of the patient in this case was so poor that treatment had to be discontinued. Three weeks ago the child was removed from the hospital and has since died of phthisis.

CASE IV.—A. V., aged five years. Diagnosis: tuberculous osteitis of the right knee. This child was admitted into the hospital November 13, 1895. The patient had a sinus over the anterior surface of the head of the tibia, which has been dressed daily for five months. In January, 1896, the applications of the acid were commenced and continued twice a week for ten weeks. One month after its discontinuance the sinus was nearly closed.

CASE V.—W. C., aged four years and six months. Diagnosis: right hip disease, third stage. The patient entered the hospital in March, 1895. In October the bone was curetted under ether. After two weeks the sinus again opened into the wound. Three months later, when I began injecting the acid, there was on the upper posterior aspect of the thigh a large sinus leading to the bone. Two minims were introduced twice a week for four months. As there was no improvement, I abandoned the treatment.

CASE VI.—A. K., aged twelve years. Diagnosis: left hip disease, third stage. This case was admitted in January, 1895. The child had an abscess opened in another hospital before entering here. An examination showed a deep sinus on the external part of the thigh and another posteriorly. The former was treated with hydrochloric acid and the latter packed with iodoform gauze at each dressing. The sinus thus treated with the acid has entirely healed, while the other still discharges profusely.

CASE VII.—W. M., aged nine years. Diagnosis: spinal disease involving the lower dorsal vertebrae. The case was admitted in October, 1894. An abscess over the twelfth dorsal vertebra was aspirated and four ounces of pus withdrawn. An incision was afterward made to establish drainage. After being dressed four times a week for eight months and no noticeable improvement resulting, I commenced using hydrochloric acid, injecting three minims twice a week for four months. At the present time the sinus is not entirely healed, but the discharge is very much diminished. The patient will remain under the same treatment for another month, as this is an unusually large sinus with more necrosis present than in the other cases of the series.

CASE VIII.—M. P., aged five years. Diagnosis: left

hip disease, third stage. The child was received in February, 1895, when an excision of the hip was performed. The patient was discharged in June, but readmitted in August, having marked infiltration about the joint and discharging sinuses on both the anterior and posterior aspect of the femur. In September the sinuses were curetted, under an anæsthetic. A few weeks afterward, however, they again began to discharge and daily irrigations of bichloride of mercury (1 to 5,000) were used. This treatment was continued for three and a half months, after which the acid was applied. Four minims were introduced into each sinus twice a week for four months and a half, and at the present writing both of them are closed.

In these eight cases I can record four apparent cures. In numbers two and five I would suggest the possibility that either the necrosed area was larger than the probe indicated, so that not sufficient acid has as yet been applied to effect its solution, or that another area of necrosis exists at some distant point not determined by the probe. Should these conditions be present, operative methods are necessary.

The conclusions which may be drawn from the above cases are as follows:

1. No evil effects have resulted from its use.
2. The use of the acid in its concentrated form is preferable.
3. When the area of necrosis is extensive, operative methods are advised.
4. Its action is limited to the necrosed area; whereas curetting may remove both diseased and healthy bone.
5. By the disintegration of the dead bone the newly formed tissue has a better opportunity for its more rapid development.

I feel warranted in stating that the further use of hydrochloric acid as a local application in the treatment of bone necrosis of tubercular origin is not only justifiable, but deserving the attention of the medical profession.

I am greatly indebted to Dr. Virgil P. Gibney, the surgeon in chief of the Hospital for the Ruptured and Crippled, for the many and valuable suggestions given for carrying out these observations.

#### THE INDICATIONS FOR PERFORATING THE MASTOID IN ACUTE AND SUBACUTE MIDDLE-EAR INFLAMMATIONS.\*

BY FELIX COHN, M. D.

In deciding whether, in a given case of acute or subacute middle-ear inflammation, the inflammation has extended to the mastoid, and whether the mastoid operation should be performed, we should not attempt to depend upon any one symptom nor should we schematize, but rather consider the symptomatology of each case

carefully in its closest details and from the complex of symptoms form our diagnosis of mastoid involvement. In one case the local symptoms might be so obscure that possibly only the general condition of the patient would decide us to operate; in another, a noticeable swelling over the mastoid would make the diagnosis of mastoid complication and the indication for operative interference obvious. In order, therefore, to formulate a scientific indication for operative interference, a careful study of the otoscopic condition, a consideration of the patient's subjective condition, a physical examination of the parts about the ear, of the mastoid, of the glands, of the skin, are necessary.

The symptomatology upon which we base our indications depends entirely upon the pathology of the occurring complications, and a brief review of these complications from a pathological point of view will therefore aid us in formulating our indications.

The post-mortem examinations of Tröltsch and Bezold have taught us that congestion of the antrum and mastoid cells is a frequent complication of acute middle-ear inflammations, and probably always present in that form of acute otitis which occurs in the course of infectious diseases. In some cases the congestion was not recognizable during life. In spite of these post-mortem findings, we all know that all cases of acute middle-ear disease do not require operative interference; as the middle-ear affection subsides the congestion and exudation in the cells no doubt disappear. These congestive conditions of the mastoid cells may be compared to the inflammations of the accessory sinuses of the nose occurring during an attack of coryza or influenza. It is very rarely that the inflammation of these sinuses terminates in the formation of abscesses, but the congestion usually disappears with the rhinitis. What the causes are which produce conditions in a mastoid requiring operative interference have not yet been fully determined. We can, however, on general principles assume that a maximum of congestion, primary and secondary microbic invasions, perhaps also the morphological and anatomical condition of the mastoid itself—as, for instance, the topographical relation of the antrum to the aditus and tympanic cavity, the size of the antrum, the number and size of emissary veins and lymphatic channels—are the ætiological factors producing those pathological states of the mastoid requiring surgical measures.

While congestive conditions frequently get well without operative interference, there are many cases of acute middle-ear disease in which the congestion is replaced by actual inflammation both in the antrum and mastoid cells as well as of the mastoid bone and its periosteum, constituting conditions of mastoid osteitis and periostitis and catarrhal and purulent inflammations of the mastoid cells, the latter condition well known under the designation of antral empyema. These pathological conditions are the ones which usually require our surgical interference. Let us, for a moment, follow the course

\* Read before the Manhattan Medical and Surgical Society.

of an antral empyema if left to itself. If the drainage is sufficient the pus may be discharged into the tympanic cavity and through the tympanum, and under favorable circumstances the abscess may be evacuated through the middle ear. If the drainage is imperfect, or the reactive inflammation very intense, the abscess, as frequently happens with children, may gradually break through into the periosteum and, creeping along the external canal and along the mastoid fissure, form a cutaneous abscess either above the auricle or immediately behind the ear, or, in some cases, from below into a submastoid or cervical abscess, or, instead of following the path just described, provided the cortex of the mastoid is not too thick, by gradually breaking through the cortex form a subperiosteal or cutaneous abscess over or in the neighborhood of the mastoid. I have so far enumerated favorable conditions. In those cases in which the mastoid happens to be abnormally dense, the empyema may become latent, producing by absorption of the pus general pyæmic or septicæmic conditions, or, if the reactive inflammation remains, perforate inwardly and upwardly through the roof of the antrum, or laterally and downwardly toward the lateral and sigmoid sinus, producing direct secondary complications, extending beyond the mastoid, well known and not too infrequently observed, such as subdural abscesses, purulent meningitis, sinus phlebitis, and purulent sinus thrombosis. The reactive inflammation in the cells causes frequently, by direct extension, a concomitant mastoid osteitis and periostitis, and, without necessarily perforating, an inflammation or an abscess of the antrum may, through extension of the inflammation along the venous and lymphatic channels in the mastoid, produce serous or purulent leptomeningitis, sinus thrombosis, metastatic cerebral abscesses, lymphangitis, lymphadenitis, and even pseudo-erysipelasous inflammations about the mastoid.

The pathological changes in the mastoid do not always go hand in hand with the condition in the middle ear; it is therefore not infrequent to find a catarrhal form of middle-ear disease accompanied by an abscess of the antral cells, or by an acute inflammation of the antrum and mastoid bone, which in their turn maintain the inflammatory condition of the middle ear and prevent the acute otitis from resolving; or, one of the cells alone, not necessarily the antrum, may contain one or two drops of pus, likewise acting as an irritative focus for the maintenance of the middle-ear inflammation. For the sake of completeness, I would also mention that a secondary involvement of the antrum or mastoid bone occurs sometimes after the middle ear may have been completely restored to a normal condition.

We have so far seen that the following complications occur in acute inflammations, which we may group into primary and secondary complications. As primary, we have found congestion of the mastoid and cells, mastoid osteitis, mastoid periostitis, empyema of the mastoid and mastoid cells; as secondary complications, subdural

abscesses, meningitis, serous or purulent, sinus phlebitis, sinus thrombosis, lymphangitis, lymphadenitis, cutaneous abscesses, and pyæmic and septicæmic conditions.

If we bear in view these pathological facts, it will be very easy to study the symptomatology of mastoid complication in acute middle-ear inflammation, and formulate the indications for mastoid operation.

The first pathological complication referred to is congestion of the antrum and of the mastoid cells. The presence of this condition, found almost invariably in all severe forms of otitis at the onset, is, as a rule, easily diagnosed by sensitiveness of the mastoid on pressure, and in very hyperæmic conditions even on touch.

The sensitiveness of the mastoid at the onset of an inflammation due to congestion is, however, no indication for operation of the mastoid. It is generally most amenable to treatment, and in most cases disappears under antiphlogistics, such as cold and leeching, or when the middle ear is relieved from its congestion, as by paracentesis. Sometimes the mastoid, in cases of noncomplicated middle-ear inflammation, may remain sensitive for some time, but the sensitiveness gradually lessens day by day, instead of increasing or remaining constant. I have seen, in cases of influenza otitis, sensitiveness of the mastoid persisting for several weeks, and the otitis heal without necessitating an operation. Both the character of the discharge and the absence of temperatures warranted expective treatment and with favorable results.

In severer cases of middle-ear inflammation, in which the mastoid congestion is replaced by actual inflammatory conditions of the bone, the sensitiveness of the mastoid does not disappear. Persistency of the sensitiveness becomes, therefore, an important cardinal symptom for the recognition of those forms of mastoid inflammation requiring operative interference. In these complications we usually find, besides sensitiveness of the mastoid, the skin over the mastoid reddened, the line of demarcation between the auricle and the mastoid indistinct, the auricle frequently standing off from the head to a greater or less degree, depending upon the amount of oedema present, and the auricle itself enlarged. These symptoms, more or less frequently present in pronounced cases of osteitis and periostitis, are obvious and important for the diagnosis of mastoid inflammation; we must not forget, of course, that some of the symptoms referred to also occur in severe forms of external otitis; as a rule, it will not be difficult to exclude these forms.

The oedema over the mastoid in furuncular affection and in cases of diffuse external otitis is, as a rule, not accompanied by sensitiveness. Although osteitis and periostitis very often occur together, not infrequently we find mastoid periostitis alone without involvement of the bone, so that the differential diagnosis between these conditions may become difficult. Fluctuation, of course, indicates the presence of a periosteal or cutaneous abscess. In those cases, however, where no pus has formed, a more

circumscribed swelling immediately behind the auricle, at the line of attachment, is usually found in mastoid periostitis, while a more diffuse, less bulging œdema over the mastoid speaks in favor of an osteitis.

In antral inflammation and antral empyema, the sensitiveness of the mastoid is likewise an important symptom, although it is not always present. Sometimes we find only certain points of selection painful on considerable pressure. A frequent point of sensitiveness is a depression immediately behind the auricle, over the upper portion of the mastoid, and slightly above the external auditory canal, a point corresponding to the position of the antrum. A second point of selection is the lateral surface of the mastoid process near the apex.

The otoscopic examination, the condition of the external canal, both in its membranous and osseous portion, the condition of the tympanum, the location of the perforation in cases of perforative otitis, the position and appearance of the drum membrane in nonperforative forms, the character of the discharge, the quantity of discharge, are all important symptoms in diagnosing mastoid complications and influencing our therapeutical procedures. In periostitis of the mastoid we shall frequently find the auditory canal in its entire length narrowed; in affections of the antrum, narrowing or bulging of the lateral wall of the osseous portion of the canal will in obscure cases aid us in our diagnosis. From the normal anatomical relation we shall not be surprised to find the upper wall, especially in its lateral portion, hyperæmic and depressed, so that a sinking of the roof of the osseous canal likewise forms a very important symptom, pointing to probable antral involvement. Of course it is hardly necessary to state that in all stenosed conditions of the canal, external or furuncular affections must be excluded.

The appearance of the tympanum is an important guide in the diagnosis of mastoid complication, and we commonly find a bulging of that part of the tympanum corresponding to Shrapnell's membrane accompanying the changes described in the posterior portion of the osseous canal. An important indication for hastening the operative interference, for instance, is an unfavorable location of the perforation interfering with proper drainage.

The character and quantity of the discharge must also be carefully considered. If, in the course of an acute otitis, the discharge becomes muco-purulent, and then finally purulent, becomes thick, of creamy consistence, and is at the same time very profuse, forming again no sooner than it is removed, showing no tendency to decrease or change its purulent character, even if there are only one or two other, perhaps obscure, symptoms present, or, if in the presence of such a discharge, the posterior portion of the usually reddened tympanum bulges, while the anterior portion appears retracted, we may almost with certainty diagnosticate antral empyema. The discharge is not always necessarily purulent. Fre-

quently the discharge may be very scant, more mucous in nature, forming thin flakes in the pus basin, and still undoubted mastoid disease requiring operative interference be present. Usually, however, in these cases other symptoms will help us to a conclusion, as in those cases we generally have conditions of mastoid osteitis or circumscribed abscess in the mastoid as the cause of the discharge. Why the discharge in these cases is not purulent may be easily understood by bearing in mind the pathology of mastoid involvements. A single drop of pus in a single cell, or even large granulations with considerable hyperæmia, may tend to keep up an inflammatory condition in the middle ear, producing desquamation and exudations from the mucous membranes. The discharge in these cases is not, as in the purulent form mentioned above, derived from the antrum, but from the adjacent portions of the tympanic cavity.

The temperatures occurring during the course of an otitis must be carefully watched, for in some cases, where the symptoms are not pronounced enough to warrant our operative interference, a sudden rise of temperature in the course of an otitis, or nightly exacerbations with normal or almost normal morning temperatures, constituting signs of retention, will sometimes render a diagnosis positive, and enable us to operate in time. As a rule, in ordinary uncomplicated middle-ear affections, where, when drainage is once established, resorption does not occur, the temperature runs a more regular course than in the complicated form. At the onset of middle-ear inflammation very high temperatures, or even resorption temperatures, may be present, but usually during the course of the otitis the temperature gradually diminishes. Sudden or steady rise of temperature, if not caused by closing of the perforation, for instance, in the course of an otitis, is a positive sign of resorption, and if accompanied, for instance, by copious discharge, an indication for immediate operative interference. As it is the object of this paper to formulate indications to operate before serious secondary complications ensue, it will only be necessary to mention briefly the symptoms pointing to such complications, as vertigo (which, by the by, occurs also in ordinary acute middle-ear affections), headaches, convulsions, chills, suggesting thrombosis or septic conditions, and all the symptomatology of brain complications and of involvements of the parts about the mastoid. In every otitis, especially if observed from the beginning, with the exception of those rare fulminating forms involving the whole ear and labyrinth, and producing death by direct extension from the labyrinth, and with the exception of the at times very severe forms of diphtheritic otitis, in which the exudation is of such a magnitude that a return to normal conditions is almost impossible even with operative interference—such cases excepted, or with cases of abnormal anatomical conditions, as openings on the roof of the antrum or tympanic cavity, we may say that secondary complications are due to neglect

to operate in time. There are, of course, a number of cases in which the symptomatology is so obscure that, without depending on experience in other observed cases, we are in doubt whether to operate or not. In doubtful cases, therefore, it is always advisable to operate even too early, instead of waiting until fatal complications render an operation futile. In obscure cases, therefore, where a positive diagnosis is impossible, the indication is to operate, not to delay. The mastoid operation is harmless; delay may be fatal.

We may formulate our indications as follows:

The presence of hyperemia and congestion alone is no indication for opening the mastoid.

The mastoid should be opened in all cases of diagnosed osteitis if under the usual antiphlogistic treatment the inflammation shows no tendency to resolution.

In pronounced cases of antral empyema in which the character of the discharge is purulent and the empyema shows no tendency to discharge completely through the middle ear.

In all cases of protracted otitis with profuse otorrhœa which show no tendency to resolve within a reasonable period, the time chosen for operation depending upon the manifest symptoms, whether, for instance, retention is present or the mastoid bone itself is involved.

In every case of acute otitis in which there are dangerous symptoms of resorption, and in which the drainage can not be established by paracentesis or by the natural perforation. In those cases, even without manifest symptoms of mastoid affection, the mastoid should be opened, in order to produce a more favorable drainage and enable a thorough cleansing of the middle ear.

In all cases of muco-purulent otitis in which the otitis is evidently maintained by mastoid involvement, the time for operation depending upon the condition of the patient and the presence or absence of symptoms pointing to retention or other complications of a serious nature.

In cases of mastoid disease, or otitis complicated by lymphangitis or lymphadenitis, in which there is an imminent danger of the formation of abscess, and in those cases in which the lymphadenitis does not tend to resolve under ordinary antiphlogistic treatment.

In cases of protracted otitis in which there are symptoms of serious secondary complications, involving danger of extension of the inflammation inward toward the brain, or downward toward the neck.

In cases of acute otitis in which complicating stenosis of the external canal prevents drainage and thorough cleansing of the middle ear.

**The Medical Standard.**—Dr. James G. Kiernan, of Chicago, has severed his connection with the *Standard* after an editorial service of nearly ten years.

## A REPORT OF THE ACTION OF ANHALONIUM LEWINII (MESCULE BUTTON).

By D. A. RICHARDSON, M. D.,  
DENVER, CO.

On the 15th of October, 1895, Mr. —, of this city, consulted me regarding repeated attacks of occipital and frontal cephalalgias, from which he suffered great pain and inconvenience. He is a solidly built gentleman, fifty years of age, and during the years 1887 and 1888 underwent, at the hands of an incompetent man in a neighboring State, a severe course of treatment for trachoma of the lids of both eyes, by which the cornea of the right eye was severely eroded and some opacity brought about. The resulting scars may be seen on the cornea at this date. His habits are correct in every way. He is well fed, a total abstainer from liquor and tobacco, and the father of a healthy family. His business up to this time has been that of a dairyman, and he is a large, strong, and well-nourished man. His weight to-day is one hundred and eighty pounds.

Thinking an error of refraction or eyestrain might be the cause of these neuralgias, I placed him in the hands of an able ophthalmologist of this city, who carefully examined his eyes, and stated positively that the neuralgias were not due to eyestrain or refraction, but might perhaps be influenced favorably by the use of proper prisms or lenses. After a careful and prolonged trial of these instruments, my patient visited me at my office on December 25th, still complaining of severe cephalalgia. I treated his stomach expectantly, and examined its contents, finding no cause for his trouble there, and gave him various prescriptions, which did him no good. On January 25, 1896, his neuralgia became general, and I was careful to make a differential diagnosis between neuralgia and acute rheumatism, the diagnosis of neuralgia being thoroughly and unquestionably established.

About this time I had been studying the accounts of anhalonium Lewinii, as sent out through the channels of Messrs. Parke, Davis, and Co., and from therapeutic indications, as especially enumerated in an article in the *Therapeutic Gazette*, which bore some similarity to indications exhibited by the train of symptoms in this patient, I at once determined, with his consent, to make a practical test of this drug in his case. Consent being given me by him, I proceeded (after vainly seeking in the stores for the drug) to procure from the laboratories of Parke, Davis, and Co. a sample of the tincture of anhalonium. These gentlemen promptly forwarded me an ounce of the tincture, and I at once notified the patient of its arrival, and immediately exposed him to its action.

The patient was given four drops of the tincture every night on retiring, and this dose was not increased. On the evening of the fourth day the neuralgia had left him, being replaced by a peculiar prickling sensation over the surface of the body, but exaggerated in the fingers and toes, and also on the soles of the feet. This sensation lasted but a short time, was unaccompanied by any rise of the temperature of the body or change in the character or rate of the pulse; neither was it especially a source of discomfort to the patient, but quite otherwise. After one week this sensation was experienced for an hour or two after taking the drug, but soon

ceased and disappeared altogether in the third week. At this time he suffered a very short but severe attack of frontal cephalalgia, which he endured for about eighteen hours, and for exactly two months since he has been totally free from neuralgia. Up to the time of this last attack, this sensation was virtually the only positive action experienced from the drug, but since that time the excretion of urine has been somewhat excessive. Especially would I remark on the clearing of the skin of pimples over the chest and back, and a marked softening of the hair, which before the exhibition of the anhalonium was dry, with a tendency to break easily.

These last symptoms, I think, fully justify the placing of this drug in the class of neurotics, as only by in some way acting on the nervous system could it remove acne vulgaris from the skin. The skin remained moist, but at no time was it bathed in perspiration; and the abnormal oiliness of this organ, which had persisted all along, was greatly improved or restored to a normal condition.

April 23, 1896, the patient and myself together visited the oculist to whom I had previously sent him, and in going over the history of the case, when that point was reached in the history of the action of the anhalonium where a large amount of urine was eliminated from the body, the doctor evinced much interest, and mentioned the probability of this drug being perhaps an especially fine solvent of uric acid. If it shall be shown that anhalonium is a solvent of uric acid from the blood, it will be one of the richest discoveries of organic medicine; for we have in this drug something which, given in continued doses of but four drops daily, will, without the slightest inconvenience to the patient or danger from poisoning, and without appreciable loss or disturbance of the metabolism of the body, cause to be eliminated from the body daily several pints of urine. I regret exceedingly the lack of a case of indubitable rheumatism or gout in which to test the action of this drug.

In Brochure No. 4, page 38, the writer mentions a varied dosage. This drug is not so poisonous as would be feared from what has been written of it, and, in the face of what has been recently written regarding the dosage of veratrum viride, one need not fear to start in with a dose of four drops in a well-nourished patient, and continue its administration daily for a long period. Like nitroglycerin, it will steady the pulse, and, in a case of cardiac dyspnoea, one drop of the tincture rapidly removed all trace of purring thrill, or *frémissement cataire*, of Laennec. This attack was due to the patient coming suddenly to this elevation above sea-level, and was not due to any organic lesion of the heart.

In my opinion, anhalonium is a superior cardiac tonic, and, like nitroglycerin, its effects are prolonged after the administration of the drug is withdrawn. After continuously taking the drug daily for two months, no symptoms of its being a sedative or hypnotic have developed. The patient during the last month has lived at an altitude of nine thousand feet, and has worked hard and lost some flesh thereby. As an adjuvant to

digitalis it might be of value, provided sufficient digitalis be given with it to produce diuresis by the skin, for the anhalonium acts well on the kidneys without anything in combination.

There has for a long time been in use a combination of phenacetine, cannabis indica, caffeine, and camphor monobromide as a succedaneum for morphine. Anhalonium in certain cases will supplant such formulae, and thus avoid the depression of the heart caused by the use of coal-tar derivatives. It is for this reason that I wish to again mention that, if it shall prove to be a solvent of uric acid, it will be of the greatest service, as the heart will be sustained by it at the same time the dangerous element is being removed from the body.

## Therapeutical Notes.

**The Treatment of Pernicious Malarial Fever.**—Dr. Klein, a physician practising in Syria, says the *Therapeutische Wochenschrift* for July 12th, recommends the following solution for subcutaneous use:

R Quinine hydrobromide.....	30 grains;
Sulphuric ether.....	180 "
Alcohol, enough to make.....	1 fl. oz.

M. A Pravaz's syringe will hold enough of this solution to contain a grain and a half of the quinine salt, and as much as ten syringe-fuls may be injected in the course of twenty-four hours. At the same time the following is prescribed for internal use:

R Camphor.....	15 grains;
Syrup of ether.....	600 "
Cognac.....	900 "
Syrup of orange peel.....	450 "
Distilled water.....	1,050 "

M. Dose, a teaspoonful.

After the paroxysm has subsided this mixture may be given:

R Quinine hydrochloride.....	60 grains;
Extract of cinchona.....	30 "
Cognac.....	1,200 "
Syrup.....	900 "
Distilled water.....	1,500 "

M. A few tablespoonfuls to be taken daily.

**Irritability of the Bladder after Delivery.**—In his new *Manual of Midwifery*, just published by the Macmillan Company, Mr. W. E. Fothergill, of Edinburgh, says that the following mixture is very useful in cases of post-partum irritability of the bladder:

R Salol.....	} of each, 2 drachms;
Tincture of hyoscyamus.....	
Infusion of buchu, enough to make 6 fluid ounces.	
M. S.: A tablespoonful three times a day.	

**The Treatment of Flatulence.**—The *Province médicale* for July 18th remarks that when the stomach is very much distended by gas in consequence of defective muscular power, the following procedure, which was recommended by Robin, should be resorted to: Open the oesophagus by drawing in some air, and at the same time lower and raise the head several times; when the opening is obtained the gas escapes without pain. This per-

formance should be practised before the gastric tension has become too great.

**Eucaine and Cocaine.**—In the *Therapeutische Monatshefte*, according to a summary in the *Wiener medizinische Blätter* for July 23d, the suggestion is made, in consequence of the burning occasionally caused by instilling a two-per-cent. solution into the eye, that Berger's plan be followed, that of instilling first a drop of a one-per-cent. solution and then, after two or three minutes, a drop of a two-per-cent. solution. Berger, it is added, uses eucaine and cocaine together in the following solution:

R Eucaine hydrochloride, } of each 3 grains;  
Cocaine hydrochloride, }  
Distilled water..... 300 "

M. The exsanguinating action of the cocaine, often undesirable, is thus avoided, and its action on the pupil and the accommodation is diminished one half.

**The Coryza of the Newborn.**—The *Indépendance médicale* gives the following formula:

R Menthol..... 1 part;  
Boric acid..... 100 parts;  
Vaseline..... 1,000 "

M. S.: Insert a portion as big as a pea into the nostril three times a day. At the end of three days, insufflate a pinch of the following powder into each nostril:

R Tale, } of each..... 75 grains;  
Boric acid, }  
Salol..... 38 "

M.

**Pruritus of the Vulva.**—In cases that are not parasitic, says the *Indépendance médicale*, M. Mussy advises the following applications:

R Finely powdered starch..... 300 grains;  
Bismuth subnitrate, } of each... 15 "  
Potassium bromide, }  
Calomel..... 8 "  
Powdered belladonna..... 3 "

M. To be applied twice a day. It is said to give almost instant relief.

When the itching affects the inner surface of the mucous membrane, it is preferable to prescribe the following:

R Infusion of mallow flowers..... 1 quart;  
Cherry-laurel water..... 750 grains;  
Borax..... 150 "

M. To be used as an injection twice a day. After each injection, the parts are to be smeared with an ointment of one part of chloroform to ten parts of vaseline.

Bernheim (*Vienna Clinical Formulary*; *ibid.*) prefers cocaine to chloroform, and gives the following formula:

(1) R Emollient ointment..... 100 parts;  
Cocaine hydrochloride..... 1 part.

M.

(2) R Pure carbolic acid..... 1 part;  
Water..... 20 parts.

M. S.: To be painted on.

**The Insomnia of Neurasthenia.**—Mouin (*Indépendance méd.*, July 1st) says the following draught is well borne for a long time:

R Paraldehyde..... 38 grains;  
Fluid extract of piscidia..... 75 "  
Syrup of cherry-laurel..... 750 "

M. S.: The whole to be taken at once in a cup of orange-flower water.

## THE NEW YORK MEDICAL JOURNAL.

*A Weekly Review of Medicine.*

Published by  
D. APPLETON & CO.

Edited by  
FRANK P. POSTER, M. D.

NEW YORK, SATURDAY, AUGUST 8, 1896.

### A SURVIVAL OF SAVAGE CREDULITY.

DR. DAN MILLIKEN, of Hamilton, Ohio, is evidently a man of comprehensive knowledge, close reasoning, rare humor, and remarkable power of expression. This we infer from a perusal of his presidential address, entitled *A Study in Credulity*, delivered before the Ohio State Medical Society at its last annual meeting. He opened with a reference to the universal tendency of savages—a tendency shared by children and degenerates—to superstition, and particularly to the superstition of regarding disease as an evil spirit, something to be enticed or driven out of the body; and he proceeded to show that a conviction akin to that superstition had dominated the humoral pathology, still survived among the laity, and even now was not altogether conquered by physicians, so that it took a man of strong mind to stand out and not finally be influenced by the notions of the people among whom he was at work. This thought, he says, often comes to him when he hears a patient speak of his disease as "it." "We often hear," he adds, "that 'it' *struck in*, with the most serious results. I have been called out of bed to see a patient who was awakened with a numbness of the toe, and straightway sent for his brother, his doctor, and his priest, lest 'it' should creep up to some vital organ and send him to the realm of shades in shameful informality. And very recently I saw a poor creature with a slowly failing heart and swelling legs who with the tincture of iodine had painted a garter about her leg in the vague hope that this might prevent 'it' from crawling up to drown her."

It was on some such notion, he thinks, that the old practice of bleeding, salivating, and giving repeated purges and emetics was founded. Up to very recent years, he says, intolerable drugs were put into the body "with a more or less definite idea of making it untenable to any other spirit than the owner, and the practice was carried so far that it was oftentimes a very nice question whether the landlord of this house of clay—the Ego himself—had not better move out and find quieter quarters." The notion of exorcising dis-

ease, Dr. Milliken imagines, has infected the surgeon, who "carries his voodoo in a dredging-box and calls it iodoform." "He doesn't precisely say that it is a lucky thing to use, though that is in his heart of hearts." "Press your surgeon hard enough, and he will tell you that iodoform slowly gives off iodine in the wound or on its edges, but he will not tell you why it is better than other substances which do the like, nor will he impart to you a reason why he does not use iodine itself in known quantity."

After picturing the humoral pathology as "only a higher form of personification of the morbid principle," which "substituted a vague and shadowy entity for the half-corporeal demon which had haunted pathology for so many centuries," Dr. Milliken says: "We do much better now. We have a pathology of the zymotic diseases which is harmonious and strictly scientific and conformable to the true spirit of induction. But it falls in my way to say, to-day, that it is not at all to the credit of our craft that the old credulity breaks out anew with every announcement of progress in bacteriology; greedy, gulping acceptance of principles, unproved and half-proved, in bacteriology is the disgrace of the day; most of us have been obliged to change front three times on the bacteriology of diphtheria, and it is certain as death and taxes that we shall play the jumping-jack through future years if we do not, after the manner of scientific men, receive valuable hypothesis as hypothesis."

Proprietary preparations, Dr. Milliken declares, "do not differ in any regard from the patent medicines which are swallowed in such quantity by the laity to feed the inextinguishable laughter of the doctors." "It is not in order," he adds, "for you or me to sneer at the girl who buys love-powders in the kitchen or madam who buys subscription books in the parlor, if we, snickering in the office, are seduced by the drummer's smooth tongue into the purchase and use of secret remedies. . . . I am told that the formula is on each bottle. The formula, indeed! The Egyptian sphinx has a very open countenance, yet the ages have not wrested her secret from her. . . . The formula on each bottle! Spare us such formulas in the kitchen, for if the cook has only the names of her ingredients hinted to her, 'combined with aromatics,' she will never be able to concretely realize the theoretic difference between pudding and bread or between plain omelet and baked custard, and the only certainties she will deal out to us will be dyspepsia and consuming wrath.

. . . There are superstitions in medicine to be sloughed; there are noble certainties to be attained. Throw away your samples and practise medicine!"

But it is not Dr. Milliken's opinion that, judged as a whole, the medical profession is credulous; its genius, he does not doubt, will meet and neutralize the evil tendency to credulity, for "it has ever been the proud boast of the doctor that he has dissipated doubt and superstition and has gone far beyond the bounds of his art to bring certainty and scientific apprehension to the world."

#### POTASSIUM IODIDE IN THE TREATMENT OF GALLSTONE COLIC.

In the *Therapeutische Wochenschrift* for July 19th Dr. Dunin states that for the last four years he has used potassium iodide in the treatment of gallstone colic with great satisfaction. He was led to this practice by having chanced to prescribe the drug for two women who, as he supposed, had syphilitic gummata of the liver. The results were very gratifying, but in two months one of the women, in whom the existence of syphilis had only been inferred, and on very slim data, returned for further treatment, and this time there could be no mistake in the diagnosis; she had gallstone colic and increasing jaundice.

Since then, Dr. Dunin has prescribed potassium iodide in all his cases of gallstone disease, about a hundred in number. He finds that it answers best in cases characterized by the frequency rather than by the severity of the attacks—cases in which the patients are worn down in general health by loss of sleep, impaired appetite, and the effects of narcotics taken for the relief of pain. Under the influence of the remedy the patients begin to feel better in a very few days, and in three or four weeks they consider themselves cured. In some of these cases the gall bladder actually ceases to be palpable, but in others, although the pains may have wholly subsided, the organ remains enlarged and manifestly contains stones.

In many instances Dr. Dunin has observed better results from the administration of potassium iodide than even from the drinking of Carlsbad water. Some of his patients who had taken the Carlsbad course without stopping the attacks have found relief in the use of the iodide, and in others whose attacks had been subdued by it the Carlsbad water actually seemed to bring them on again. Still, he thinks the best way to get the upper hand of the disease for good is by alternately

taking the iodide and the Carlsbad waters. His usual practice is to keep the patient on the use of the iodide for four or five weeks and then have him take the waters. He gives from five to ten grains of the potassium salt twice a day. He is doubtful whether it acts by facilitating the solution of the stones in the bile or by relaxing the biliary passages and so favoring their expulsion into the intestinal canal.

### MINOR PARAGRAPHS.

#### THE OFFICE OF CORONER IN NEW YORK.

The physicians of New York are for the most part of the opinion that there is nothing to do with the office of coroner but to abolish it, but it is satisfactory to learn that the coroners themselves, some of them at least, seem to have become aware of the fact that their office needs reforming. To that end, a conference between some of the coroners and an invited party of physicians was held in the coroners' office on Tuesday evening. Professor Withaus is reported to have said at that conference that for fifty years the office had not furnished evidence that had led to the conviction of anybody for murder by poisoning.

#### ITEMS.

**Infectious Diseases in New York.**—We are indebted to the Sanitary Bureau of the Health Department for the following statement of cases and deaths reported during the two weeks ending August 4, 1896:

DISEASES.	Week ending July 28.		Week ending Aug. 4.	
	Cases.	Deaths.	Cases.	Deaths.
Typhoid fever.....	17	7	17	8
Scarlet fever.....	44	3	35	5
Cerebro-spinal meningitis....	7	6	0	0
.....	105	7	110	7
Diphtheria.....	192	23	146	18
Tuberculosis.....	139	105	183	103

**The Late Surgeon Fessenden, of the Marine-Hospital Service.**—Surgeon-General Wyman has issued the following circular letter, dated July 31st:

*To the Medical Officers of the United States Marine-Hospital Service:*

It is with regret that I have to announce to the medical officers of the service the death, on the 23d instant, from a complication of heart and kidney affections, of Surgeon Charles Stewart Davis Fessenden. Surgeon Fessenden was the senior surgeon of the corps, having served since April 4, 1861—a period of more than thirty-five years. He was born in Portland, Maine, on February 23, 1828, and was of a family noted in the annals of his native State and the nation. His father, General Samuel Fessenden, was for many years a leader at the bar of Maine, and his eldest brother, William Pitt Fessenden, was the distinguished senator of that State, and during the administration of President Lincoln became secretary of the treasury. Two nephews of Surgeon Fessenden rose to the rank of brigadier general during the civil war, and others have been prominent in private life, two of them in the profession of medicine.

Surgeon Fessenden was fitted for college at the Portland Academy, and in 1844 entered Harvard University, where he pursued his studies for a year; leaving Harvard, he became a student at Bowdoin College, from whence he was graduated in 1848.

He studied medicine under Charles W. Thomas, M. D.,

of Portland, Maine, and attending medical lectures at the Medical School of Maine and also in New York, and was graduated in 1851 from the Medical School of Maine. From 1853 to 1856 he was physician in charge of the Portland City Hospital, after which date he became a private practitioner until his appointment as surgeon in the Marine-Hospital Service, in 1864.

During the period of his membership in the corps, he served as commanding officer at the ports of Portland, New York, St. Louis, Norfolk, Louisville, and Mobile. During this period he was also a member of three boards of medical officers convened for the examination of applicants for the service and of eight boards convened for the physical examination of candidates for admission to the Revenue Cutter Service, besides serving on various special details as inspector.

On account of the failure of his health in the fall of 1895, he was ordered to appear before a board of medical officers for physical examination, and in accordance with the report of the board was placed on waiting orders on November 22, 1895.

During the few months which intervened between this date and his demise Surgeon Fessenden resided at Salem, Massachusetts, at which place his death occurred.

**Lithiopiperazine.**—According to the *Wiener medizinische Blätter* for July 16th, this new proprietary compound has been found to be efficacious in cases of gout and urinary lithiasis in which simple piperazine had failed. It is made by Dr. L. C. Marquart, of Beuel, and is in the form of a soluble granular powder or in tablets of fifteen grains each, of which from one to three are to be taken daily.

**Guaiacol in the Treatment of Swelled Testicle.**—Dr. Tavitani (*Médecine moderne*, March 18, 1896; *Indian Lancet*, June 16, 1896) applies guaiacol, either pure in amounts of from thirty to forty-five grains or in the form of this ointment:

R Guaiacol..... 5 parts;  
Vaseline..... 30 "  
M. In mild cases, three or four applications suffice.

**Excessive Sweating of the Feet**, according to the *Therapeutische Wochenschrift*, may be treated to advantage by dusting the following powder into the socks:

R Alumnol, of each..... 4 parts;  
Aristol.....  
Starch..... 15 "

M.

**Creosote in the Treatment of Pulmonary Tuberculosis.**—Gilbert, says the *Therapeutische Wochenschrift* for July 5th, recommends the following mixture for subcutaneous injection:

R Creosote..... 375 grains;  
Camphor..... 225 "  
Aristol..... 150 "  
Eucalyptol..... 450 "  
Sterilized neat's-foot oil, enough to make..... 8 fl. ounces.

M.

Each cubic centimetre of this solution contains a grain and a half of creosote, six tenths of a grain of aristol, and three quarters of a grain of eucalyptol.

**Army Intelligence.**—*Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from July 19 to August 1, 1896:*

BUSHNELL, GEORGE E., Captain and Assistant Surgeon. The extension of leave of absence granted him is further extended one month.

CLENDENIN, PAUL, Captain and Assistant Surgeon, is granted leave of absence for one month.

MEARNS, EDGAR A., Captain and Assistant Surgeon, is granted leave of absence for three months, to take effect on or about August 3d.

WARE, ISAAC P., First Lieutenant and Assistant Surgeon, is granted leave of absence for three months, on surgeon's certificate of disability.

BUSHNELL, GEORGE E., Captain and Assistant Surgeon, is relieved from duty at Fort Hamilton, New York, to

take effect upon the expiration of his present leave of absence, and ordered to Fort Assiniboine, Montana, for duty at that station, relieving EGAN, PETER R., Captain and Assistant Surgeon. Captain Egan, upon being thus relieved, is ordered to Fort Hamilton, New York, for duty.

MCELDERRY, HENRY, Major and Surgeon, is granted leave of absence for one month, to take effect on or about August 5th.

WORTHINGTON, JAMES C., Major and Surgeon. The leave of absence granted him on account of sickness is further extended one month.

**Naval Intelligence.**—*Changes in the Medical Corps of the United States Navy for the Week ending July 25, 1896:*

COOK, F. C., Assistant Surgeon. Detached from treatment at the New York Hospital and ordered to proceed home.

COOK, G. H., Medical Director. Detached from special duty at Philadelphia and ordered to take charge of the hospital there.

FARWELL, W. G., Medical Inspector. Ordered to special duty at Philadelphia attending officers.

KINDLEBERGER, D., Medical Director. Detached from duty in charge of the hospital at Philadelphia and ordered home to await orders.

MORRIS, L., Assistant Surgeon. Detached from Indian Head Proving Ground, ordered home, and granted leave of absence for one month.

**Marine-Hospital Service.**—*Official List of the Changes of Stations and Duties of Medical Officers of the United States Marine-Hospital Service for the Sixteen Days ending July 31, 1896:*

CARTER, H. R., Surgeon. Directed to inspect Marine-Hospital Service at Tampa, Fla. July 28, 1896.

PECKHAM, C. T., Passed Assistant Surgeon. Directed to report to Surgeon Godfrey, chairman of board for physical examination. July 24, 1896.

BROWN, B. W., Passed Assistant Surgeon. Granted leave of absence for six days. July 23, 1896.

STEWART, W. J. S., Passed Assistant Surgeon. Granted leave of absence for four days. July 17, 1896.

DECKER, C. E., Assistant Surgeon. To proceed from Battle Creek, Mich., to St. Louis, Mo., for duty. July 21, 1896.

PROCHAZKA, EMIL, Assistant Surgeon. Granted leave of absence for twenty days. July 23, 1896.

#### Board Convened.

Board convened to meet at Port Townsend, Wash., for the physical examination of PECKHAM, C. T., Passed Assistant Surgeon. GODFREY, JOHN, Surgeon, chairman; STIMPSON, W. G., recorder. July 24, 1896.

#### Promotion.

BANKS, C. E., Passed Assistant Surgeon. Commissioned as Surgeon. July 27, 1896.

#### Death.

FESSENDEN, C. S. D., Surgeon, died at Salem, Mass., July 23, 1896.

#### Society Meetings for the Coming Week:

MONDAY, August 10th: Gynecological Society of Boston; Burlington, Vermont, Medical and Surgical Club; Norwalk, Connecticut, Medical Society (private).

TUESDAY, August 11th: Medical Society of the County of Rensselaer, N. Y.; Newark (private) and Trenton, N. J., Medical Associations; Clinical Society of the Elizabeth, N. J., General Hospital and Dispensary; Northwestern Medical Society of Philadelphia; Practitioner's Club, Richmond, Kentucky; Richmond, Virginia, Academy of Medicine and Surgery.

WEDNESDAY, August 12th: New Mexico Medical Society (Socorro); Medical Societies of the Counties of Albany and Allegany (quarterly), N. Y.

THURSDAY, August 13th: Medical Society of the County of Cayuga, N. Y.; South Boston, Massachusetts, Medical Club (private).

FRIDAY, August 14th: Cleveland Medical Society; Medical Society of the Town of Saugerties, N. Y.

## Births, Marriages, and Deaths.

### Married.

CLARK—HENDERSON.—In Deasonville, Mississippi, on Thursday, July 30th, Mr. Charles Clark and Miss Mamie Henderson, daughter of Dr. C. R. Henderson.

### Died.

BOATNER.—In Victoria, Texas, on Thursday, July 30th, Dr. E. S. Boatner.

EMERSON.—In Milford, Pennsylvania, on Monday, August 3d, Dr. Vincent Emerson, in the seventy-fourth year of his age.

POTTER.—In Newburgh, N. Y., on Monday, August 3d, Dr. Franklin W. Potter, in the sixty-second year of his age.

SWIFT.—In New York, on Wednesday, July 29th, Dr. Samuel Swift, of Yonkers, N. Y.

## Letters to the Editor.

### REFLEX EPILEPSY.

60 WEST FIFTIETH STREET, NEW YORK, August 1, 1896.

To the Editor of the *New York Medical Journal*:

SIR: Dr. Ranney's letter on reflex epilepsy in your issue of July 18th contains no answer to my queries of July 4th. He does not produce the cases of epilepsy cured by eye treatment, nor does he name any of the "hundreds of medical men of repute" whose credibility, honesty, and skill I was supposed to have called in question.

My critic intimates that he has cases of cure recorded in his books, but not yet reported. Does any one believe that the doctor would fail to rush into print at once with the report of a cure if he had one recorded in his books? Why such concealment of cures, when he has already reported so many failures?

In his first letter (June 20th) he asks if I am "familiar with the later methods of investigating defects in adjustment of eye muscles," and in this last he asks "How many of the clinical cases of Dr. Peterson or those observed by others whom he mentions were ever subjected to eye treatment in the hands of any oculist with a large experience in the treatment of heterophoria?"

If the doctor had known how dangerous these questions are, he would certainly have remained silent. Does he know how many patients with incurable epilepsy are now under treatment by neurologists who had previously undergone treatment by himself and other oculists in the hope of a cure? What does he suppose has become of the patients on whom he has committed a thousand tenotomies? What does he suppose has become of the innumerable patients on whom those who think as he does have operated?

The fact is that the claims of Dr. Ranney regarding

the efficacy of eye treatment are not and will not be substantiated.

Let me call his attention to an article in the *New York Medical Journal* for July 2, 1892, on "The Radical Cure of Epilepsy and Other Neuroses," by "Dr. R. U. Greenough," by a new method known as "testicular and mammary equilibration." It seems that this author and Dr. Smith cure cases of epilepsy and other neuroses by equilibrating the testicles in males and the mammary glands in females. In eighty-seven cases of chronic epilepsy there were fifty per cent. of cures and 49.9 per cent. of amelioration, the latter being organic cases.

The principles of this new treatment are as follows:

In normal conditions the left testicle is more dependent than the right, which is explained by the necessities of corporeal equilibrium. The right side of the body being larger and stronger than the left, there is a tendency to compensation for such inequalities, and the normal somatic equilibrium is maintained by the greater pendency of the left testicle in the male and the left mammary gland in the female. Dr. Smith had observed in certain nervous diseases that there was hyperpendency of the right testicle or mammary gland, and indeed that there were several insufficiencies in equilibration that by proper treatment resulted in the cure of serious nervous diseases, such as epilepsy, insanity, chorea, and the like. These physicians designated such conditions generically as heterophoria, testicular or mammary as the case might be, and described varieties, such as hypophoria, hyperphoria, esophoria, and exophoria. The correction of these insufficiencies sometimes required the use of simple devices, such as adhesive plaster, suspensory bandages, and so forth, but operations were occasionally needed, such as excision of the skin in the supramammary or inframammary region, or of a portion of the scrotum. Sometimes rather more severe operations were undertaken. The reader is referred to the original for further details.

Now, were I to attack the stand taken by "Greenough" and Smith, were I to call their theories absurd, their deductions ridiculous, their statements unsubstantiated by facts, their whole position unsound and unscientific, they would need but to quote Dr. Ranney's letters in full with the mere substitution of a few nouns and names in order to occupy the same relative position as does he in regard to scientific neurology.

The reiteration and repetition of untenable theses and animadversions against a critic are not answers to criticism.

Give us incontrovertible facts!

FREDERICK PETERSON.

#### MEDICAL EDUCATION IN ILLINOIS.

Chicago, August 2, 1896.

To the Editor of the *New York Medical Journal*:

SIR: Audiatur et altera pars. In the *New York Medical Journal* for July 25th, in an article entitled "Medical Education in Illinois," Dr. Julius Grinker, of Chicago, condemns the existence and action of some of the medical colleges in Chicago in a very drastic manner.

Undoubtedly the author rises with perfect right against so-called "manufactories of doctors," but he is evidently partial in regard to the so-called night schools of medicine. We have day colleges as well which are nothing else than manufactories of doctors. Naturally, this evil should be combated with word and act. However, we should be just and impartial.

Harvey night school is not known to me. But, knowing the Harvard Night School of Medicine, I emphatically object to Dr. J. Grinker's argumentations, and maintain that the author was biased in his condemnation of the above-mentioned institution.

Does the author know this institution personally? Did he ever listen to the original and genial Dr. W. T. Eckley's lectures on anatomy, the scientific and scrupulous work of Louisa Martin, M. D., professor of pathology, the excellent and thorough work of our bacteriologist and chemist, Professor H. Wightman? Did he ever see the skillful work in surgery (capital as well) of the venerable A. H. Tagert, professor of clinical surgery, and in fact of the whole faculty, which is not a collection of madcaps or swindlers, but is composed of excellent men of high professional standing who know and control their subject perfectly, and who work conscientiously and honestly? Did the author ever come in close contact with those students whom he so sarcastically designates as clerks and stockyards people, slaughtering cattle; who enthusiastically and with earnest devotion take advantage of this plan of education and listen to the lectures, work, and study, and indeed deserve the greatest praise, the more so because, after a hard day's work, they do not hesitate to make the best of their leisure hours in acquiring knowledge for useful work, instead of wasting their time in saloons and gambling houses, detrimental to their health, pocket, and mind?

Among the students of Harvard Medical College are many professional men of good education—lawyers, pharmacists, etc.—whose financial condition as well as professional work do not allow them to attend a day college, but who nevertheless are anxious to enrich their knowledge to benefit themselves and others.

The undersigned is one of them. Being in a profession which is as remunerative as the medical, it is not of consequence to me to earn my livelihood with the help of a doctor's diploma. Being a druggist for twenty-one years, I took a liking to my profession and to related sciences. Having no opportunity to attend day lectures, I matriculated in a night school. I study and work with enthusiasm, and am sufficiently intelligent to understand that any lack in lectures I am obliged to make up at home with the aid of books and manuals; and I assure the author of Medical Education in Illinois that after graduating I shall make a better physician than many graduates of the Rush, P. & S., and other medical colleges who have none, or a very poor idea of pharmacology, incompatibility of drugs, etc., and who protect manufacturers of proprietary articles with real harm to their patients.

Furthermore, I believe that in schools where there are only a hundred students the individual gets a better advantage of lectures and more practical direct information than in the large, renowned colleges with an enrollment of from six hundred to a thousand students. Besides, a big firm can not make any more out of a stupid and lazy fellow than a small and modest one, while an industrious man, who is impressed with the importance of his future task, certainly will work scrupulously equally at home and at school to obtain the necessary education.

I do not wish it understood that I am an adherent of the existing system or an antagonist of reasonable reform. I considered it my duty to defend an institution which I know well, and which Dr. J. Grinker attempts to rob of the right of existence and competency.

I consider it advisable that every student of medicine

before matriculation should pass an examination before a State examining board, and that one law should bind every one; but I oppose any plan of taking away the opportunity to study from persons who can not afford to give up their work until they are able to establish themselves in a new vocation—such plans being dictated by prejudice or false judgment.

ADAM SZWAKART, Ph. G.

## Proceedings of Societies.

### AMERICAN NEUROLOGICAL ASSOCIATION.

*Twenty-second Annual Meeting, held in Philadelphia, on Wednesday, Thursday, and Friday, June 3, 4, and 5, 1896.*

The President, Dr. F. X. DERCUM, of Philadelphia, in the Chair.

**The President's Address.**—The president delivered an address entitled *The Functions of the Neuron*. He dwelt at great length upon the various views advanced by Nansen and quoted several abstracts from this well-known author's work. Speaking of naked axis cylinders, Dr. Dercum stated that they were in all likelihood a physiological impossibility in the cerebrum, for were they numerous we could suppose nothing but a constant overflow of stimuli from one cell to another and consequent inco-ordination, not only of thought, but also of action. This was the view advanced by Nansen. The speaker stated that the question had arisen in his mind as to whether the neuron was not an absolutely fixed morphological element, and whether it did not possess a certain though perhaps limited power of movement. He said he realized the practical value and the wide application of this idea, and had examined the literature to see whether a similar interpretation of nervous phenomena had occurred to others, and to gather such facts, if any could be brought forward in its support. He found that this thought had occurred independently to three observers, one in Germany and two in France. Ramon Cajal, however, opposed the theory of the mobility of the neuron, and maintained, on the other hand, that the neuroglia cells possessed a great deal of mobility. He pointed out, for instance, that the neuroglia cells of the cortex were at times stellate and at others much elongated. Their processes had numerous short arborescent and plumed collaterals. Two phases could be observed in them: first, a state of contraction, in which the cell body became augmented while the processes were shortened and the secondary branches disappeared, and, secondly, a state of relaxation during which the processes of the neuroglia cells were again elongated. Ramon Cajal further maintained that the processes of the neuroglia cells in reality represented an insulating or non-conducting material, and that during the period of relaxation they penetrated between the arborizations of the nerve cells and their protoplasmic processes and rendered the passage of nerve currents difficult or impossible. On the other hand, when the processes of neuroglia cells were retracted, the various nerve-cell processes which they had before separated from each other were permitted to come into contact. It seemed as if Ramon Cajal admitted the very thing against which he contended.

Turning our attention for the moment to the subject of hysteria, we should see what a flood of light might be cast upon this hitherto obscure and mysterious subject. Take the simple example of an hysterical paralysis and see how easily it might be explained. The neurons of a certain area of the cortex, for instance, retracted the terminal branches of the neuraxon to such an extent that the latter were no longer in contact or sufficiently near to the neurons in the spinal cord which supplied the muscles of the paralyzed parts. When power was suddenly re-established in hysterically palsied limbs, it simply meant that the terminal branches of the cortical neuraxon, previously contracted, were again extended so as to re-establish the proper relations with the spinal neurons. It would be interesting to follow out the ideas here brought forward in their application to the various phenomena presented by hysteria.

Turning to hypnotism, we could see what a ready explanation it afforded of the phenomena presented, and, leaving this field entirely, we could see of what enormous value this interpretation of cortical action was for normal mental phenomena, taking, for example, the familiar instance of sleep. Numerous other ideas also suggested themselves in relation with the view here advanced.

### Acute Non-suppurative Hæmorrhagic Encephalitis.—

Dr. J. J. PUTNAM, of Boston, read a paper with this title, and gave a sketch of the literature of the disease, which had been mainly contributed by the German writers, the latest of whom was Oppenheim, of Berlin. The principal symptom groups were: 1. That described by Wernicke as due to hæmorrhagic softening mainly confined to the neighborhood of the third ventricle. 2. That described by Strümpell and others as attending more diffuse lesions of the hemispheres. 3. It was possible that the hemiplegia of children might be due to a similar lesion involving the cortex, as Strümpell had formerly suggested, and certain acute spinal lesions might belong in a similar category. Oppenheim had reported a number of cases showing that, however grave the symptoms of this disease might be, the outcome might be favorable. Dr. Putnam related the case of a young boy who had been attacked suddenly, two weeks after having been ill with the mumps, with paralysis of motion of both eyes and lids. Deafness, coma, impairment of swallowing, right hemiparesis, and double optic neuritis had been present. At the end of three months, however, he had recovered, although there was slight double vision, with a little impairment of hearing and eyesight, and ever since the illness he had been subject to epileptoid attacks of short duration. These attacks were gradually becoming less frequent. Reference was also made to another case which had been reported by the speaker in 1892, in which, besides other serious cerebral symptoms, including double optic neuritis, temporary loss of hearing had also occurred. The cases reported by Oppenheim were given in outline, and the interesting fact was noted that his patients, like the one he referred to, had been mainly children. An analysis of these reported cases was also presented.

Dr. L. C. GRAY, of New York, asked if in any of these cases there had been retraction of the neck.

Dr. PUTNAM stated that he was not certain as to its presence in his own cases, but it had been present in the other reported cases.

Dr. GRAY thought that the best macroscopical description of hæmorrhagic encephalitis had been given

by Elam some years ago. He said that in all the cases he had seen fatal results had ensued. In many instances the diagnosis had been attended with extreme difficulty. He had generally been willing to diagnose these cases as meningitis.

JOSEPH COLLINS, of New York, had observed a case of hemorrhagic encephalitis which corresponded with the description given by Oppenheim. He read the report of the autopsy, which had shown old leptomeningitis, hemorrhagic encephalitis, and a pachymeningitis hemorrhagica. There was no case on record in which these three conditions had been found associated.

Dr. B. SACHS, of New York, said that the recognition of this form of cerebral disease showed a distinct advance in neurology. He had observed four cases, in which two of the patients had recovered and two had died. In one case there had been some doubt as to whether it had been meningitis or not, as there had been slight retraction of the neck, but no positive coma. He looked upon it as a milder disease than basilar meningitis. In one of the patients who had recovered, the cerebral symptoms had appeared simultaneously with the fever. The former had lasted four days and had left the patient with slight ptosis and paresis of the external rectus.

Dr. GRAY asked if in fatal cases more violent symptoms had been shown than in those in which recovery had occurred.

Dr. PUTNAM replied that in some of the more violent cases recovery had ensued. In general the rapid development of severe coma was considered an unfavorable sign. It was frequently quite difficult to distinguish this condition from meningitis. He believed that the severity of the symptoms depended on the amount of poison absorbed into the circulation. We did not yet know the exact significance of retraction of the neck, which was a very unreliable diagnostic sign. In one of his own cases of influenza with symptoms of encephalitis, which occurred in an elderly person, the brain had been found to be only oedematous. Sometimes changes were unrecognizable with the naked eye.

**Cerebral Complications of Raynaud's Disease.**—This was the title of a paper by Dr. WILLIAM OSLER, of Baltimore. After referring to the frequency with which Raynaud's disease was met with in forms of insanity, he said that in a few cases cerebral manifestations which were due apparently to vascular changes and similar to those which developed in the peripheral parts had been described. In the case of a man in his wards, which had been reported in 1891 by Dr. H. M. Thomas, epileptic attacks had occurred in the winter months only, in connection with local asphyxia and superficial necrosis of the ears. The patient had also had hemiglobinuria. In another case, that of a woman aged fifty-two, during a period of six years local syncope and asphyxia had occurred at intervals in the fingers and in the hand of the right side, sometimes with aphasia, and on several occasions with transient paralysis of the right arm and leg. In the final attack the patient had died of gangrene of the right hand and arm. Weiss's case was believed to be the only other instance in which aphasia had complicated the disease. In a third case the patient had had "falling attacks" of an indefinite character with local asphyxia of the legs between the knee and the ankles.

Dr. RIGGS desired to know how often death had been seen to follow this disease.

Dr. OSLER answered that it was rarely fatal. This was the second fatal case with which he was familiar. The literature, however, indicated a number of fatal cases. He considered the complications as having no direct relation with the disease. The associated conditions were rarely serious.

**The Development of Crinism at Various Ages.**—Dr. PUTNAM exhibited a series of photographs showing the appearance of a patient at various periods, ranging from infancy to puberty.

**Tumor of the Thalamus.**—Dr. WALTER CHANNING, of Boston, read a paper with this title, and related the following case: The patient was an unmarried woman of good heredity, by occupation a school teacher. She was of an active, nervous temperament, and had been the subject of hay fever and asthma until the spring of 1895, when she had come under the care of a so-called hay-fever specialist, and had escaped the usual attack. Before her admission into the hospital, on November 29, 1895, she had been for some weeks mildly exhilarated and extravagant in her ideas, but not enough so to interfere with her work until the 22d. The only symptoms she had complained of were headache and insomnia. Her disease had been diagnosed by an alienist of experience as mild acute mania when she had entered the hospital. Since her death her friends had stated that she had had weakness of the left arm before leaving them, but nothing had been said of this when she had entered. She had been mildly exhilarated, with expansive delusions and hallucinations of taste and smell. She had been unable to stand, because of weakness in the left leg, and her left arm had been weaker than the right; there had been no power to move it above the elbow. Headache, not severe or localized, had existed. There had been little nausea. The pupils had been equal in size and had reacted to light. The eyes could not follow the finger. There had been no ophthalmoscopic examination. The weakness in the left side had not been so marked at the beginning as to attract special attention. Afterward its significance had become apparent. The patellar reflex had been slightly exaggerated and alike on both sides; the plantar reflex had been moderate; the color of the urine had been normal, its reaction acid, and its specific gravity 1.022; urea had been normal and the uric acid in excess; the red blood-corpuscles were 4,801,000 and the white 12,400. The mild maniacal excitement had continued for the first week after admission. The patient had been very restless in bed, moving her head from side to side and throwing her right arm over her head. She had also often folded her arms rigidly across the chest, and had clinched the fingers. After the first week she had slowly sunk into a stupor from which it had been difficult to rouse her. The physical symptoms of central disturbance had rapidly become more marked. There had been entire loss of motion in the left arm and the left leg and, later on, in the right leg; there had also been extreme extension of both legs. The jaw had become relaxed and interfered with respiration. The tongue had fallen back into the mouth. Breathing had become jerky and irregular toward the end and, finally, the relaxed jaw could not be replaced, and death had ensued. The autopsy had been made by Dr. E. Willis Taylor, of Boston, who had found a boggy, cystlike looking mass extending back an inch behind the posterior border of the optic thalamus and forward to the junction of the caudate nucleus with the thalamus, the mass apparently having involved the latter

in its entire extent. Microscopical examination had proved the tumor to be a vascular glioma. The mental symptoms in this case seemed to have been quite unlike those of the usual cases of brain tumor recorded, in which depression, dullness, irritability, stupor, and even pronounced dementia were found. Several interesting questions arose, said the speaker, as, for instance, Which symptoms probably presented themselves first, the mental or the physical? Why should there be so much mental disturbance in such a case? Was the mental trouble an accident, and independent of the tumor? If not, how could it be satisfactorily explained? What diagnostic value did mental symptoms possess in cases of brain tumor?

Dr. WHARTON SINKLER, of Philadelphia, thought that the appearance of mental symptoms in thalamus tumors was of much clinical interest. In his experience, somnolence and mental symptoms were of frequent occurrence.

**Hemiplegia and Dementia.**—Dr. GEORGE J. PRESTON, of Baltimore, presented a specimen from a patient with hemiplegia and dementia which showed a tumor occupying the right hemisphere and a condition of condensing osteitis of the skull.

Dr. CHARLES K. MILLS, of Philadelphia, said that tumors of the brain had not only been confounded with acute mania, but also with general paresis. It was sometimes very difficult to distinguish. It was not known that tumors limited to the thalamus produced any characteristic symptoms. They occasioned mental symptoms on account of their destruction of associated cerebral fibres.

Dr. SACHS had seen a case of brain tumor in a child in which mental symptoms had predominated. The autopsy had revealed a large tumor in the right frontal lobe. He did not feel convinced that the mental symptoms in Dr. Channing's case were attributable to the growth in the thalamus. Why might not this patient have had the mental disease independent of the tumor?

Dr. THEODORE DILLER, of Pittsburgh, mentioned a case of tumor of the cerebellum in which the earliest symptoms had been mental. The unexpected often happened in cases of brain tumor.

Dr. CHANNING thought that the coincidence of symptoms was quite remarkable in the case reported.

**The Ectal Relations of the Right and Left Parietal and Paroccipital Fissures.**—This was the title of a paper by Dr. BURT G. WILDER, of Ithaca, N. Y. The parietal and paroccipital fissures might be either completely separated by an isthmus or apparently continuous. When they were so continuous ectally there might still be an ental and concealed vadam or shallow. Disregarding the vadam on the present occasion, the ectal relations of the two fissures might be designated as either continuity or separation. That continuity occurred more frequently on the left side had been noted by Ecker, Cunningham, and the writer. Hitherto, however, statistics had included unmated hemispheres as well as mates from the same individuals. The following statement was based upon the cerebriums of fifty-eight adults of both sexes and various nationalities and characters. The speaker had examined forty-eight; the ten others had been accurately recorded by Bischoff, Dana, Jensen, and Mills.

So far as these fifty-eight individuals were concerned, the most common combination—namely, left continuity and right separation—was decidedly the rule with the moral and the educated, and less frequent with the

ignorant, the unknown, the insane, and negroes, and it did not occur at all in murderers. The only instance of the reverse combination (left separation and right continuity) had occurred in an insane Swiss woman. The only two known to be left-handed represented the more frequent combination of left continuity and right separation. These statistics suggested many special queries and problems, some of which were briefly indicated. But the speaker wished this to be regarded as a preliminary communication and asked the co-operation of other members in the effort to obtain satisfactory results in larger numbers, particularly of the brains of well-born, moral, and educated persons.

**Does Antisyphilitic Treatment prevent the Occurrence of the Diseases of the Nervous System which are considered Syphilitic in Origin?**—Dr. JOSEPH COLLINS, of New York, pointed out that certain diseases of the nervous system occurred sequentially to syphilis with such frequency that they were rightfully looked upon as syphilitic in their origin. These diseases were tabes, general paralysis, syphilitic spinal paralysis, and such exudative conditions as cerebral thrombosis. After briefly reporting the history and treatment in nearly a hundred cases observed in the hospital, the dispensary, and private practice, the speaker concluded as follows: 1. Exudative and degenerative diseases due to syphilis were most likely to show themselves at the end of the third and the beginning of the fourth decade of life. 2. Thorough and prolonged administration of antisyphilitic remedies during the activity of the virus did not seem to materially prolong this time limit. 3. Active and prolonged antisyphilitic treatment seemed to prevent the development of such diseases as locomotor ataxia and general paresis. This was true of degenerative diseases, though treatment might also have some effect in preventing the exudative diseases of the nervous system, such as syphilis of the spinal cord, disease of the blood-vessels, etc. 4. Cases of tabes and general paresis in which syphilis was confessed, in which treatment had been most desultory and incomplete, were not more liable to the early development or to the severe manifestations of either of these two diseases than those in which the treatment had been all it should be. 5. The administration of antisyphilitic remedies in the most approved way did not fulfill the requirements of cure, and syphilis was often an incurable disease.

Dr. PUTNAM referred to a case in which prolonged and thorough antisyphilitic treatment had been employed, yet symptoms of degenerative nervous disease had appeared later in life.

Dr. GRAY said that the facts in Dr. Collins's paper were not detailed as to the symptoms of syphilis or as to the exact treatment. In many instances of suspected syphilis an absolutely positive diagnosis was at times almost impossible.

Dr. SACHS, on the whole, agreed with Dr. Collins. In the vast majority of cases, however, he said, the treatment of syphilis did not prevent the development of tabes or of general paresis. A better way to have arranged statistics would have been to take all cases of syphilis and ascertain if they led to nervous disease later in life. The worst cases of syphilis of the nervous system occurred in those who had never received any treatment. He spoke of a patient who had had pronounced general paresis a year after the initial infection. In late cases it was often difficult to prove the relationship between syphilis and the nerve lesion.

Dr. P. C. KNAPP, of Boston, agreed with Dr. Sachs, and did not believe it wise to withhold antisyphilitic treatment where it seemed to be indicated. He asked Dr. Collins if his cases showed that the development of nervous disease bore any relation to the severity or character of the primary or secondary manifestations of syphilis. Where the cutaneous symptoms were pronounced there was usually less nervous disturbance.

Dr. OSLER said that his experience was diametrically opposed to Dr. Collins's views. The majority of severe cases of nervous disease which occurred in syphilis were in those who had been either badly treated or not treated at all. Early, thorough, systematic, and prolonged treatment would prevent the development of degenerative disease of the nervous system in later life.

Dr. N. E. BRILL, of New York, asked how the author could reconcile with his statistics the fact that antisyphilitic treatment frequently cured incipient tabes and parietic dementia.

Dr. DILLER had seen nervous disease develop in spite of early antisyphilitic treatment.

Dr. PRESTON expressed the opinion that the irregularity with which endarteritis occurred was often overlooked. He had been unable yet to establish the relationship between antisyphilitic treatment and endarteritis. Nervous disease was of a milder type in those who had received careful early treatment, and more marked in those who had not.

Dr. PATRICK said that the author's statistics did not prove that treatment was ineffectual, and thought that the nervous diseases might be due to other causes. Where vigorous treatment was carried out for a brief period and then discontinued, late syphilitic disease of the nervous system was more likely to develop.

The PRESIDENT maintained that it was hardly fair to draw conclusions from two diseases, such as tabes and general paresis, as Dr. Collins had acknowledged that they were not always due to syphilis. The degenerative affections might occur in cases in which there had been thorough treatment.

Dr. COLLINS wished it understood that he had no theories to advance, but had merely tabulated the results of these cases. Particular inquiry had been made in the cases detailed as to the kind of treatment, and in many instances satisfactory knowledge had been obtained. He was not willing to concede that cases which had been referred to by one of the speakers, in which the symptoms of tabes and general paresis had disappeared under antisyphilitic treatment, were genuine cases of tabes or general paresis, but cases of pseudo-tabes and pseudo-paresis, in which the lesion had been exudative and not degenerative, such as was characteristic of these two diseases, and it was his belief that in these cases antisyphilitic treatment was of benefit. He had purposely refrained from saying anything of gummata and had confined himself to the systematic syphilitic diseases of the nervous system.

**The Prognosis and Duration of Attacks of Mental Disease.**—This was the title of a paper by Dr. HENRY R. STEPMAN, of Boston.

Dr. CHANNING called attention to the fact that a general misunderstanding prevailed in the community as to the curability of insanity. It was much more curable than was supposed. General paresis should not be classified among the insanities. The character of the disease had changed in the last fifty years, and our views and classification had therefore changed.

Dr. GRAY said that to speak of insanity as an entity was as if one were to speak of all disease as an entity, and then go back to the old Carlyle tables of mortality for the prognosis of coryza, pneumonia, tuberculosis, typhoid fever, and cholera; while to refer to the old statistics of Pliny Earle was like referring to the hospital results of thirty or forty years ago for guidance in the treatment of the present day. If we were to accept the statistics of results of the insane asylums, we were justified in analyzing their record, and then we were startled to find that no new type of mental disease, no original pathological observation, no new departure in treatment, and not one text-book had ever come from an American asylum, despite the thousands of patients and the millions of dollars they had had at their command.

**Paraplegia from Hæmorrhage into the Spinal Cord due to Pernicious Anæmia.**—Dr. C. E. RIGGS, of St. Paul, read the report of a case, and presented a series of spinal-cord sections. The paper was discussed by Dr. Patrick, Dr. Osler, and Dr. Putnam.

(To be continued.)

## SOCIETY OF ALUMNI OF BELLEVUE HOSPITAL.

Meeting of March 4, 1896.

The President, Dr. PARKER SYMS, in the Chair.

(Concluded from page 136.)

**Report of Five Cases of Uterine Retrodisplacement treated by Vaginal Fixation (Mackenrodt).**—Dr. FREDERICK HOLME WIGGIN read a paper with this title (see page 186).

Dr. BARROWS said that he had been greatly interested in Mackenrodt's operation. He had never done it himself, for he had doubted what would be the ultimate result of the operation. There could be no question that the immediate results were good. Now that a fair number of these operations had been recorded, a number had been reported in which very serious obstruction to labor had been met with in subsequent pregnancies. It had been found that the uterus developed along the posterior wall very much more than along the anterior wall, owing to the fixation of the anterior face of the uterus to the anterior vaginal wall, and that consequently the cervix was carried up behind, nearly or entirely out of reach. Ruehl had reported two hundred and thirty-five cases of Mackenrodt's operation done by himself, in ten of which pregnancy had occurred. These patients he had followed to their confinements. Seven of the ten had been confined with difficulty. In the other three cases the cervix had been almost out of reach, and version had been done for relief of the condition. Strassmann and Graefe had each reported a case of Caesarean section made necessary by this same condition, and with fatal result in each instance. He believed that Mackenrodt had expressed himself as being anxious to abandon the operation.

Dr. BROTHERS said that he had been among the first to try the Mackenrodt operation, about a year and a half ago. The first case had been that of a nulliparous woman in whom the result had been imperfect, probably because of his imperfect knowledge of the techniques. The second case had been in a multipara in whom the immediate result had been good. The case had not been seen subsequently. In the third case also the immediate result had been good, but the patient had become preg-

nant, and had miscarried in the third month. After this miscarriage the retroflexion had recurred. The fourth case had been one of vaginal section for the removal of the appendages. The uterus had been fixed, with good result. In the fifth case, vaginal section had been done, and the uterus again fixed to the vagina. It had yielded a good, permanent result. The sixth case had been in a multipara in whom, at the same sitting, the cervix had been repaired, the anterior and posterior vaginal walls narrowed, and the perineum repaired, with good result. The seventh case had been in a multipara with posterior adhesions, which had been broken up and the uterus fixed to the vagina, with good result. It was true that the operation did not imperil the patient's life, but these patients often suffered considerably after the operation. He also had not observed bladder symptoms after the operation. Both Dr. Jacobs, of Brussels, and Dr. Vineberg, of New York, had accidentally passed the finger through into the bladder. The risks after the operation had been described by Dr. Barrows—at least two Caesarean sections had been demanded. Personally he had seen two cases of suppuration follow the operation of vaginal section for removal of diseased annexa, and he believed that they were due either to septic surroundings or septic ligatures. Both patients had, however, done well because the location of the incision had allowed of a free escape of pus. Mackenrodt had done two hundred operations before he had expressed his disapproval of it, hence one should be slow to follow him in his new operation.

Dr. WIGGIN said that he was rather surprised to learn that Mackenrodt had abandoned his operation, because in last September he had met a gentleman who had just come from Mackenrodt's clinic and he had told a different story. In his own mind, the difficulty experienced in subsequent labors appeared to be due to the insertion of the sutures too low down on the vaginal wall. He could not see why there should be any danger of rupturing the bladder in dissecting up from the uterus, for in his cases this part of the operation had seemed to him quite easy of performance. He had employed this same method of dissecting away the bladder in many other cases of pelvic surgery. If the bladder was wounded, it certainly would be very easy to repair the damage done.

**Rupture of the Bladder from Fracture of the Pelvis; Death in Three Hours.**—Dr. J. W. S. GOULEY presented the pubes and ischial rami together with the ruptured bladder of a man twenty-three years of age who, on January 28, 1896, had been crushed between a railway car and a stanchion. The patient had been conveyed to Bellevue Hospital immediately after the accident, in a state of shock, from which he had not rallied, and had died in the course of three hours. The post-mortem examination had revealed multiple fractures of the pelvis with complete separation *en masse* of the pubes and ischia, extravasation of blood in the ambient intermuscular spaces, and an abundant extravasation of urine and blood in the retroperitoneal, pelvic, and hypogastric connective tissue. The anterior wall of the bladder, midway between its neck and summit, had been torn through longitudinally at about an inch to the left of the median line, the rent, an inch in length, allowing the urine to escape into the neighboring connective tissue. Another larger rent had been discovered near the upper fundus of the bladder; this, however, penetrated to but not through the mucous membrane. These two lacerations had been made, probably, by a sharp bony

fragment. Only one kidney, weighing eleven ounces, had been found, but there had been two ureters with corresponding orifices in the bladder.

**Sacculated Bladder containing Two Calculi.**—Dr. GOULEY presented the bladder of a man sixty-four years of age who had died on the 15th of October, 1895, six days after his admission to Bellevue Hospital. When seen, the patient had been in such a feeble condition that no treatment had been undertaken, save the use of opiates to alleviate his suffering and of the catheter to relieve the bladder distended with purulent urine. The cause of death had been pyelonephritis, consequent upon chronic calculous cystitis. The prostate had been only moderately enlarged, but the vesical walls had been much thickened. From the lower fundus of the bladder, close to the base of the prostate, had projected a thick, rounded sac filled with purulent urine and containing a flat stone. This sac, of a capacity of six ounces of fluid, had communicated with the bladder by a single orifice a third of an inch in diameter. Another sac, of a capacity of two ounces, had been detected in the upper and left side of the bladder, communicating therewith by an aperture of about a third of an inch. In the bladder had been found a flat stone, of about the same size and form as that which lay in the larger sac, and measuring seven eighths by two thirds by three eighths of an inch. The stone found in the sac probably had slipped into it when very small, and had attained its present dimensions by slow accretion. Sacculatation in the anterior part of the lower vesical fundus must be of rare occurrence, owing to the anatomical characters of this part of the bladder and of the underlying structures; the most frequent sites of vesical sacs were the sides of the bladder above the tracts of the ureters.

**Hæmatoma of the Ovary and Broad Ligament.**—Dr. A. B. JOHNSON presented such a specimen. It was interesting because rather rare in the experience of the general surgeon, and because the case had simulated very closely cases of perforative appendicitis. The patient, a woman, thirty-five years of age, had never had children. She had been ill four days when first seen by him, and had given a typical history of appendicitis with the occurrence of perforation about twenty-four hours previously. She had had pain in the right iliac fossa, and there had been general distention and tenderness of the abdomen when she was seen, with vomiting, fever, and rapid pulse. On opening the abdomen over the region of the vermiform appendix, a large quantity of fluid blood had escaped, and the appendix had appeared to be perfectly normal. On opening the abdomen in the median line, a tumor had presented, resembling a gangrenous sigmoid flexure. After it was freed from the surrounding adhesions, the tumor had been found to consist of the tube and ovary in which the broad ligament had suffered one complete twist. The interference with the circulation had led to the effusion of blood into the cavity of the tube, as well as into the ovary and ligament, and to a partial rupture, through which the fluid blood had escaped. The tube and ovary had been ligated off, and the belly washed out with saline solution, and closed except for a small gauze drain. She had made a good recovery.

**"Photography by the Roentgen Ray."**—Professor M. I. PUPIN, of Columbia College, delivered an interesting address on this subject. He also demonstrated the working of the apparatus, and exhibited lantern slides of a series of Roentgen-ray photographs, to show what progress had already been made in this new art.

## Miscellany.

**The Employment of Large Doses of Bismuth Subnitrate in the Treatment of Ulcer of the Stomach.**—At a recent meeting of the Medical Society of Munich, a report of which is published in the *Gazette hebdomadaire de médecine et de chirurgie* for July 16th, Dr. Cramer stated that he had used Pleiner's method in the treatment of ulcer of the stomach with some modifications. This method consisted in the employment of from a hundred and fifty to three hundred grains of bismuth subnitrate suspended in six ounces of warm water, which was to be introduced into the stomach through a tube after previous lavage. Dr. Cramer thought it unwise to employ the tube and lavage, as it might cause accidents, and it was not practicable outside of hospital practice. He simply administered the drug to the patients before a meal and having them in a posture fitted to the supposed situation of the ulcer; that is, if the ulcer occupied the posterior wall of the stomach, the patient assumed the dorsal posture; if the ulcer was found to be in the anterior wall, the patient lay on his face in such a manner that the subnitrate could be deposited over the ulcer. At the end of five or ten minutes the water was withdrawn through the tube, and the patient remained in bed for half an hour, after which time he could take his first meal. This treatment had always given very good results at the end of two weeks or a month; in some cases a veritable cure was observed. In depositing the subnitrate on the surface of the ulcer Dr. Cramer thought that it formed a sort of protecting and antiseptic layer, which favored cicatrization and protected the nerve fibres against irritation, which was the prime cause of the very acute pains of which the patients complained. The employment of large doses of bismuth subnitrate should, however, be practised very cautiously, as fatal results had often been observed.

Dr. Tappeiner said that the symptoms of poisoning by bismuth subnitrate resembled those of mercurial poisoning. The black color of the buccal and the intestinal mucous membrane was particularly characteristic; the nervous system was also affected. When the subnitrate was introduced under the skin or brought into contact with a denuded surface it caused symptoms of poisoning. It might also be supposed that in cases of ulcerating lesions of the stomach the internal administration of this drug would produce the same result, although in such cases the power of absorption of the ulcerated surface was greatly diminished.

Dr. von Ziemssen stated that he had employed this drug for a long time combined with opium, with very satisfactory results. Large doses should not be employed, and he considered the introduction of the tube into the stomach to be dangerous in all cases.

**The Hæmstatic Properties of Gelatin.**—At a recent meeting of the Société de biologie, a report of which appears in the *Gazette hebdomadaire de médecine et de chirurgie* for July 16th, M. P. Carnot stated that M. Dastre and M. Floresco had shown that gelatin greatly increased the coagulability of the blood, and he thought it would be well to consider its employment as a hæmstatic, for coagulation of the blood was a mechanical defense of the organism to insure hæmostasis.

M. Carnot stated that he had used a five- or ten-per-cent. solution of gelatin heated to 95° F. and had arrested serious epistaxis in cases of hæmophilia, also

metrorrhagia by intra-uterine injections, and hæmorrhage which followed wounds of the hand, etc.

**Subconjunctival Injections of Corrosive Sublimate in Myopia.**—The *Gazette hebdomadaire de médecine et de chirurgie* for July 16th contains a report of the sixth annual meeting of the Congress of Russian Physicians, at which Dr. Preunoff stated that he had employed injections of corrosive sublimate in a hundred cases of myopia, and the results had led to the following conclusions: 1. Subconjunctival injections of corrosive sublimate caused the rapid disappearance of the symptoms of muscular asthenopia, and enabled the patients to resume their occupations. 2. The symptoms of irritation of the chorioid and retina, as well as the photopsia, also disappeared rapidly. 3. Recent inflammatory phenomena in the fundus of the eye and hæmorrhages in this region disappeared, provided the treatment was prolonged for a sufficient time. 4. The visual acuity, the diminution of which depended upon modifications of the media of the eye, increased sometimes to a considerable extent. 5. In no case had any complications set in; several times the progress of the myopia had been arrested. 6. In order to prevent a relapse and a return of inflammatory symptoms of the chorioid and retina, the treatment should be continued for six or eight months.

Dr. Mandelscham said that he had never been able to ascertain the good effects of these injections in similar cases.

Dr. Kraiski had observed that these injections diminished pain in severe affections of the eye, but that they did not arrest the process unless in exceptional cases, notably those in which there were syphilitic lesions. In order to prevent symptoms of irritation, he thought that the corrosive sublimate should be replaced by a more soluble and less irritating mercurial salt.

**Anticholera Serum.**—In the *British Medical Journal* for July 18th Dr. Nakawaga, of Tokio, states that Professor Kitasato's report of December 6, 1895, has been widely referred to in many journals with not a few misunderstandings, and to correct such mistakes the following abstract has been prepared with the professor's permission:

The inoculations for obtaining the antitoxic serum were begun in May, 1895, with cholera bacteria isolated from one of the earliest cases in the last epidemic. At the time the serum treatment was begun at Hiroo Cholera Hospital (August 6, 1895) the supply of the serum was therefore very limited, and what was used for injection in the beginning was not all of the desired strength. Nevertheless, some of the animals had already attained quite a considerable degree of immunity, and the efficiency of the serum of such animals is seen in the following experiments:

1. Without entering into details of the experiments, it may be stated that for guinea-pigs 0.02 milligramme (0.0002 c. cm.) was sufficient to protect against the inoculation of several times the fatal dose of cholera culture—the serum and the virus being injected into the peritoneal cavity simultaneously. The guinea-pigs used in this as well as in all experiments mentioned in the report weighed from two hundred to three hundred grammes.

2. If the serum is injected subcutaneously, the quantity required to obtain similar results was found to be considerably larger (0.02 c. cm.).

3. To determine the antitoxic property of the serum, using the word antitoxic in the strict sense, experiments

were made with the toxine obtained by warming the twenty-day-old cholera bouillon culture for twenty minutes, at the temperature of 131° F. The bouillon culture thus sterilized (the so-called "toxine") was found to be fatal to guinea-pigs in the dose of 1.5 c. cm. when injected into the peritoneal cavity. The antitoxic serum was found to neutralize the effect of 2 c. cm. of sterilized bouillon when injected simultaneously into the peritoneal cavity in the dose of 0.2 c. cm.

Experiments for ascertaining the curative action of the serum were carried on in this wise: A number of guinea-pigs were inoculated with several times the fatal dose of the virus, so that the untreated animals died within twenty hours after such inoculation. At the expiration of each successive hour injections were made in some of the animals, and it was shown that those treated not later than seven hours after the inoculation of the virus were cured, while those in which the injections were made after the lapse of seven hours could not be saved by the serum. In other words, if injected during the first third of the entire course of the disease (thus experimentally produced) the serum can be considered curative.

Two hundred and seventy patients suffering from cholera were admitted into the Hiroo Hospital, Tokio, from August 6 to November 10, 1895, and a hundred and thirty-eight died. Rate of mortality, 51.1 per cent.

Anticholera serum was employed in a hundred and ninety-three cases only, owing to the fact that the supply of serum was inadequate to allow it to be used in all cases.

The rate of mortality among Japanese in nearly all the previous epidemics, as well as that of the last epidemic, has always been about seventy per cent. Without claiming to draw, from a number relatively so small, the final conclusion that the serum treatment was attended with the reduction of twenty per cent. in the mortality statistics, it is evident at least that the result of the new therapy was not an unfavorable one. Moreover, there is reason to believe that with a sufficient supply of very efficient serum the rate of mortality can still be lowered.

Subsidiary results of serum injections are similar to those of diphtheria antitoxine: 1. Urticaria (very common). 2. Arthralgia (observed in eighteen cases only). 3. Myalgia (observed in six cases only).

Obviously there must be difference in the prognosis of each case according to the time which elapsed before the patient came under treatment.

Three cases of cholera were observed in children under two years of age. A bacteriological examination, microscopical as well as cultural, was made in every case.

**Some Observations on the Opium Habit.**—In the March and June number of the *Chinese Medical Missionary Journal* Mr. Philip B. Cousland publishes an article on this subject in which he remarks that all, except a few interested people, agree as to the hurtfulness of the use of opium in excess. From five to ten per cent. of the population of China are habitual smokers, and of these, ten per cent. are "opium sots." It has been stated that the habit is generally practised in moderation, and that when it is so practised injurious effects are not apparent. The meaning of moderation here, Mr. Cousland says, is evidently that there are no injurious effects, and if this is so, he does not agree to the conclusion that the habit is generally practised in mod-

eration, for his experience has been that it is rare to find no evidences of injurious effects—moral, physical, or social. In the vast majority there are more or less idleness, inactivity, want of energy, diminished capacity for work, chronic constipation, sometimes alternating with diarrhoea, loss of flesh, dusky complexion, weakening of will power, general shiftiness of character, and an intensified natural disregard for truth. These are seen in the vast majority of the so-called moderate smokers. The social effects are by no means the least. In the part of China of which he writes, says the author, a man earns from fifteen to twenty cents a day. Few opium smokers use less than ten cents' worth of opium daily, and many use more. A man may exist on five cents a day, but he can not support himself and his family even on twice that sum; hence the average moderate smoker is insufficiently nourished, his wife and children are half starved, and much misery and wrongdoing result. It may be said that this is not the result of the opium, that it is due to its expensiveness. To this it may be replied, says Mr. Cousland, that but for the habit or slavery to the pipe it would not occur, and therefore it is the result of the moderate use of opium. One year six hundred opium smokers registered at the Swatow Hospital for treatment. The great majority of them were moderate smokers, and yet they could not stop smoking. Why, asks Mr. Cousland, if moderate smoking is so harmless, do they wish to stop? Surely these injurious results are apparent enough to the careful observer.

Opium, continues the author, can not be put on a par with alcohol. Most men may take the physiological quantity of alcohol daily and yet give it up whenever required. It is not so with opium. If a man smokes a small quantity daily for a few months, he has formed the habit and can not easily give it up. With determination he could endure the suffering and break off the habit, but if he keeps it up, his will power deteriorates and he can not give it up. This shows that there is no parallel. Opium is much the stronger narcotic poison of the two. The rapidity with which it takes hold of a man in the ordinary run of cases is paralleled only in instances in which there is an hereditary alcoholic history. Who, he asks, ever heard of a moderate drinker going to a hospital or to his physician to be broken of the habit, and suffering severely while undergoing the deprivation? The habitual users of opium can not be fairly compared with habitual moderate users of alcohol; the only fair comparison would be to place the habitual opium smoker on a par with the man who uses alcohol in more than physiological doses, that is, an alcoholic or chronic "soaker."

Mr. Cousland states that he has come across no evidence that malarial affections have anything to do with the use of opium in China; it is a social vice. The agriculturists, as a class, are not addicted to its use, in spite of their exposure to malarial affections, and the habit flourishes to a greater extent in towns and cities than it does in small villages.

**Spontaneous Rupture of the Heart.**—In the *Lancet* for July 18th Dr. T. N. Kelynack relates the following case: An old man about sixty-eight years of age was brought to the Manchester Royal Infirmary in an unconscious condition. The patient's friends stated that he had been at his place of business as usual all day. He had, however, complained of feeling unwell. In the evening he went out into the back yard and was

found shortly afterward on the ground in an unconscious condition. He was immediately brought to the accident room of the infirmary, which he reached some ten minutes after being found. He had during the previous six months had two or three fainting attacks. His memory had been deficient and his relatives had noticed that he had been somewhat strange in his conduct and peculiar in his manner for some time past. When first examined he was quite unconscious and lay perfectly still, breathing quietly. There was no paralysis, spasm, tremor, or rigidity. The pupils were equal, normal in size, and reacted to light. In about five minutes he began gradually to recover consciousness and was able very soon to speak. He complained of pain in his head and seemed somewhat dazed and disinclined for any exertion. He could, however, walk, although he was generally very feeble. His mental condition was peculiar, and it was deemed advisable to admit him as an inpatient. He slept well during the night and the next morning declared himself as feeling very well. All discomfort about the head was gone. There were no nervous symptoms. He was able to speak clearly and could answer questions, but he still showed signs of mental feebleness. The respiratory and digestive systems appeared to be normal. The cardiac dullness was not increased and on auscultation of the heart nothing abnormal could be detected, except a slight accentuation of the first sound at the apex. The radial arteries did not appear to be markedly atheromatous. The urine was dark-colored and of specific gravity 1.018. It contained a fairly large amount of albumin, but no casts. During the day he appeared bright and cheerful and took his food well. About midnight he became restless and got out of bed and began dressing, saying that it was morning and he must go home. The following morning—that is, on the third day after admission—he seemed perfectly well and arrangements were made for his friends to remove him. Soon after midday he quite suddenly had a “fit” somewhat of the nature of an epileptic seizure. Convulsive spasmodic movements occurred in the right hand and arm. The mouth was drawn to the left side and the right side of the mouth moved very little. He was quite unconscious and the breathing was stertorous. His hands were cold and no pulse could be detected at the radials. In about ten minutes the stertorous breathing was replaced by irregular shallow gasps, the interval between which became progressively longer until death occurred a few minutes later. On auscultation over the cardiac area just before the last respiration no cardiac sounds could be heard. The pupils at the beginning of the attack were markedly contracted, but later became slightly dilated and unequal.

Forty-eight hours after death the author made a post-mortem examination of the body, with the following results: Externally the body was that of a well-formed, moderately nourished old man. The face was pale. The pupils were small and unequal, the right being a little the smaller; there was slight arcus senilis. There was extensive oedema of the chest wall, which was of a somewhat solid character; and also anasarca of the back, loins, buttocks, and back of the thighs, but little or none of the extremities. Rigor mortis was well marked. Internally the cavity of the pericardium was distended with recent blood-clot. The heart was small and contracted. Along the postero-external border of the left ventricle blood-clot was slightly adherent to the visceral layer of the pericardium. On

gently separating it a small, irregular, blood-infiltrated area was exposed and in it a small rupture. The ventricular wall at the point of rupture was very much softened, exceedingly friable, and of a dark brownish-red color. The necrotic area appeared to be infiltrated with blood and extended almost from the endocardium to the rent in the pericardium. The whole of the myocardium forming the left ventricle was unduly soft and flabby. The cavities, orifices, and valves of the heart appeared to be fairly healthy. There was, however, slight induration and fenestration of the aortic cusps. The coronary arteries were extremely atheromatous, especially the branches supplying the left ventricle. These were much calcified and seemed practically occluded. The aorta was extremely atheromatous; no aneurysm was present. The pleuræ were congested and there were large areas of pleuritic fibrosis over the apices of both lungs, which were congested and very oedematous; there was no tubercle or hæmorrhage. As regards the abdomen, the peritonæum was normal. The gastro-intestinal tract was congested. The liver, which was enlarged, weighed fifty ounces, and was slightly congested and fatty. The gall bladder was normal, and the pancreas was congested. The kidneys were slightly enlarged, weighed four ounces and a half each, they were a little granular, and the capsule was somewhat adherent; a large simple retention cyst was observed in the right organ. The ureters were normal and the bladder was distended with urine. The prostate was not appreciably enlarged and the testicles were apparently normal. The dura mater was adherent to the skull-cap, the vessels were congested, and there was slight subdural hæmorrhage along each side of the falx cerebri. The pia-arachnoid was congested; there were no hæmorrhages. The brain was congested and slightly oedematous; no hæmorrhages were present; there was a small patch of softening at the posterior border of the right lobe of the cerebrum. The cerebral vessels were extremely atheromatous.

The ventricular wall at the seat of rupture was carefully hardened in alcohol and imbedded in celloidin, and sections were cut by means of a freezing microtome. A large number of preparations, both stained and unstained, were subjected to examination. The chief changes were as follows: The muscular fibres stained badly; they had a more or less homogeneous appearance, and their nuclei and striæ in many places had disappeared. They were much broken up and separated by an extensive infiltration of blood. Between the necrotic muscular elements, and in parts displacing them, was a fibrouslike network with blood-corpuses. In some parts the corpuses were not distinct, but formed a mere granular structureless mass. The affected portion extended up to the pericardium. Leucocytes infiltrated the whole area more or less, but were especially abundant at the borders of the hæmorrhagic parts. The branches of the coronary arteries in the sections were practically obliterated.

In this case, says the author, a progressive atheromatous arteritis of the coronaries, especially of those branches supplying the left ventricle, seemed to have led to a localized softening—a condition of myomalacia—and, the vascular obstruction finally becoming complete, a so-called hæmorrhagic infarct had resulted, with final rupture through the necrotic and blood-infiltrated area.

It is important from a medico-legal point of view, says Dr. Kelynaek, to remember that death is not always

instantaneous in rupture of the heart. This case is a striking example. The rapidly developing oedema and the epileptoid attack formed points of considerable clinical interest, which tended rather to confuse than to aid in the diagnosis.

**A Remarkable Case of Hypothermia.**—In the *Journal des praticiens* for July 18th M. H. Claude relates the following case: The patient, a man twenty-five years old, had fallen unconscious in the street. His face was very pale, his eyes were surrounded by a blue circle, and the skin was cold and marked with violet-colored spots. The extremities were cyanosed, the pulse was imperceptible, and the heart beats could scarcely be heard. The rectal temperature was 101.6° F. Four hours later, under the influence of a therapeutic agent, it fell to 96.4°; there was great weakness and the pulse remained imperceptible. On the following day the temperature rose to 98.3°. It was learned that the patient had some time before been seriously poisoned by the vapors of mineral acids, and that he had given up his work on account of his loss of health. A slight subicteric hue and a notable diminution in the urine were observed. The urine contained albumin and urobilin, and showed hypazoturia. The stools were decolorized and slimy; the liver was painful spontaneously and on pressure. During the following days the temperature rose until it reached 104° one day. The general condition, however, was better; the urine became more abundant, the proportion of urea increased, and the reaction of the biliary pigments appeared. At the end of three weeks convalescence set in, the strength returned, and the albumin and the urobilin disappeared. The liver remained somewhat large. At the end of two months the patient left the hospital. A bacteriological examination of the blood was negative.

The cause of all these symptoms, says M. Claude, appeared to be an hepatic alteration. The sensitiveness of the liver, the subicteric hue, the decolorization of the stools, the diminution of urine, the hypazoturia, and the urobilinuria all indicated an intense lesion of the liver. It seemed that the mineral poisoning had altered the liver or predisposed it to a new form of poisoning, probably of gastro-intestinal origin. The vitality of the hepatic cells was profoundly affected, and symptoms of hepatic insufficiency manifested themselves suddenly. The diseased liver, however, repaired its lesions, the hepatic cells resumed their function, and the hepatitis completely disappeared, apparently, at least.

**The Serum Diagnosis of Typhoid Fever.**—The *Journal des praticiens* for July 11th contains a report of a recent meeting of the Académie de médecine at which M. Dieulafoy read a paper on this subject. He alluded to a very important communication recently made by Vidal in regard to a method of making an exact diagnosis in typhoid fever. The procedure was as follows: A pure culture of Eberth's bacilli was made in bouillon, and a preparation of this culture was placed under the microscope, when isolated and moving bacilli could be seen.

In order to make a comparison, a mixture was made in a test tube, which was composed of ten drops of the bouillon with the culture of Eberth's bacilli and a drop of blood, or, better still, of serum which had been separated from the blood of the finger of a typhoid-fever patient. A preparation of this was then placed under the microscope, and a startling phenomenon could be seen. The bacilli were not isolated and moving as in the pre-

ceding preparation; they had lost their mobility and had become agglutinated and joined together in masses, and in the preparation on the plates they had formed large islets which were separated by wide spaces; these spaces were also dotted with bacilli which were less mobile, undefined in appearance, and, as it were, drawn finally toward the masses, with which they became blended in their turn. This was the unvarying and startling phenomenon to be seen.

From this, said M. Dieulafoy, the diagnosis was made. A patient who furnished a serum which could cause similar changes in a bouillon of typhoid-fever culture, which manifested such agglutinant and immobilizing properties, was certainly attacked by typhoid fever, and by no other disease.

This phenomenon had been observed many times by Vidal with the serum taken from patients who were in different stages of the disease. On the other hand, Vidal had collected the serum from fourteen patients who were suffering from other diseases, such as nephritis, tuberculosis, pneumonia, icterus, rheumatism, etc., and experimented with it as described in the foregoing paragraph, and found that the bacilli remained moving and isolated.

The procedure, said M. Dieulafoy, was simple and rapid; it needed no laboratory material and no coloring matter; it was sufficient to have a culture in bouillon of Eberth's bacilli, which could be kept for several weeks, a microscope with the objective immersed, and a few drops of blood or of the serum of the blood of a typhoid-fever patient.

M. Dieulafoy stated that he had made a test of this method at the Hôpital Necker, and that he had easily obtained the same results.

**Low-temperature Pasteurization of Milk.**—The August number of the *Archives of Pediatrics* contains an article on this subject by Dr. Rowland G. Freeman, who states that during the year 1891 to 1892 he made a study of the subject of pasteurization and his conclusions at that time were that pasteurization of milk at 167° F. was superior to other methods of sterilizing, and that if it was kept for twenty minutes at that temperature it was fairly sterile. He felt convinced, however, that 167° F. was as high as milk should be sterilized at, and he was inclined to think, moreover, that a lower temperature would be as safe, had it not been for the high temperature at which the thermal death point of the *Bacillus tuberculosis* was placed at that time by those who had experimented for the purpose of determining it. From one point of view, he says, there is a decided advantage in pasteurizing milk below 158° F., for at about that temperature the change in the taste of milk takes place, while if it is heated to a lesser degree it retains its original flavor. This change is unnoticed by infants who are brought up on sterilized milk, but it is often strongly objected to by older children and adults. If, then, milk can be satisfactorily pasteurized below 158° F., a distinct advantage is gained in the unchanged taste of the milk, and the chemical changes are also avoided to a greater degree.

Pasteurization at 155° F., says Dr. Freeman, as far as the ordinary air bacteria are concerned, gives almost as good results as that at 167° F. The milk is freed from almost all the living germs, and those pathogenic bacteria which are most likely to cause disease are also destroyed. The only pathogenic bacterium which is not destroyed by a short exposure to a temperature of 140° F. or less is the *Bacillus tuberculosis*; but there is evi-

dence that this micro-organism is destroyed by a temperature of less than 158° F., and, indeed, by a temperature of 140° F. of sufficient duration. The evidence of the more recent observers, he says, seems to him sufficient for a conclusion that a temperature of 149° F. kept up for fifteen minutes is sufficient to kill tubercle bacilli, and he recommends pasteurization at between 149° F. and 167° F. for the following reasons:

1. It destroys almost all the ordinary air bacteria which occur commonly in milk.

2. It destroys the *Bacillus tuberculosis*, the *Bacillus typhosus*, the *Bacillus diphtheriæ*, and many other pathogenic bacteria.

3. It causes no change in the taste of the milk and prevents those chemical changes in milk which are produced by higher temperatures.

4. It is possible to pasteurize accurately at this temperature without the use of a thermometer.

**The American Electro-therapeutic Association.**—The secretary, Dr. Emil Heuel, has issued the following announcement: The sixth annual meeting will be held in Boston, on Tuesday, and Wednesday, September 29th and 30th, and Thursday, October 1st. This meeting promises to be very successful, and much interest is shown in all quarters. There will be two discussions of importance on electro-therapeutics, interesting reports of all standing committees, and several scientific lectures, with demonstrations and stereoscopic views, including those of the Röntgen rays and electric principles in the treatment of disease. The exhibition is expected to be a feature of more than usual interest. The following list includes the names of the members of the different committees: Dr. Robert Newman, of New York; Dr. Holford Walker, of Toronto, Canada; Dr. D. B. Deaver, of Reading, Pa.; Dr. Robert J. Nunn, of Savannah, Ga.; Dr. Emil Heuel, of New York; Dr. William J. Morton, of New York; Dr. G. Betton Massey, of Philadelphia; Dr. William J. Herdman, of Ann Arbor, Mich.; Dr. Wendell C. Phillips, of New York; Mr. A. E. Kennelly, of Philadelphia; Dr. D. R. Brower, of Chicago; Dr. M. A. Cleaves, of New York; Dr. O. B. Douglass, of New York; Mr. W. J. Jenks, of New York; Dr. J. H. Kellogg, of Battle Creek, Mich.; Mr. R. G. Brown, of Brooklyn; Dr. Charles R. Dickson, of Toronto, Canada; Dr. L. Hall-Brown, of Brooklyn; Dr. E. C. Riggs, of St. Paul; Mr. J. J. Carty, of New York; Professor A. E. Dolbear, of Boston; Dr. W. H. White, of Boston; and Dr. Frederick H. Morse, of Melrose, Mass.

**Albuminuria after Vaccination.**—Professor Emil Peiper and Mr. Siegfried Schnaase, of Greifswald (*Berliner klinische Wochenschrift*, 1896, No. 4; *Deutsche Medizinische Zeitung*, July 20, 1896), give the results of their investigation on a large scale of this subject, which had previously been treated of by Falkenheim, of Königsberg. The authors made four hundred and seventy-four urinary examinations in a hundred and twenty-two cases of primary vaccination, and found slight opalescence of the urine nine times in seven children, a proportion of 5.73 per cent. In no instance was there evidence of nephritis, and no relation was observed between the occurrence of albuminuria and the number of the pocks or the severity of the fever. Among fifty-four cases of revaccination, there were ten of slight albuminuria, but one of them should be excluded, that of a person with mitral insufficiency in whose urine albumin had been found before the vaccination. In revaccinated recruits they found albuminuria in 10.63 per cent. of

the cases. They regard vaccinal albuminuria as of no special significance.

**The Discovery of Iodine in the Hypophysis Cerebri.**—It will be remembered that Professor Baumann, who discovered thyreiodine, stated in the *Münchener klinische Wochenschrift* last April that he had failed to find iodine in the hypophysis cerebri. But Dr. Julius Schnitzler, of the Francis Joseph Hospital, of Vienna, and Dr. Karl Ewald, of Professor Albert's surgical clinic, announce in the *Wiener klinische Wochenschrift* for July 16th that at the very time when the Munich journal containing Baumann's statement reached them they were engaged in testing the hypophysis for iodine. They continued their experiments, using large quantities of hypophysis—as much as two hundred and ninety grains in one instance and three hundred and sixty-five grains in another—and found, to their astonishment, evidence of the presence of considerable amounts of iodine. They had followed Baumann's process strictly, and when they acquainted him with their results he ascribed them to the large quantities of material used. Schnitzler and Ewald believe that the discovery of iodine in the hypophysis is another step in our knowledge of the vicarious relations between this gland and the thyroid.

**Non-poisonous White Lead.**—The *Fortschritte der Medicin* for July 15th contains a note by Dr. M. Kirchner, of Hannover, on an article by K. B. Lehmann which appeared in a recent number of the *Hygienische Rundschau*. It seems that a Glasgow white-lead company, some time ago, put lead sulphate on the market under the name of non-poisonous white lead, and that the council of inquiry of the League of German Artists warmly recommended it. Lehmann, however, states that he had previously succeeded in killing a cat in thirty-six days by the daily administration of three grains of lead sulphate. Although it is insoluble in simple water, considerable lead is dissolved by the addition of dilute hydrochloric acid or a solution of common salt. Lehmann therefore gives warning against the use of this pigment, and remarks in regard to the artists' council: "How hazardous it is for chemists who have made no special study of biology to pose as experts in special toxicologic-hygienic questions!"

**The Central College of Physicians and Surgeons, of Indianapolis.**—The *Indianapolis Sentinel* for July 24th speaks of the reconstruction of the college building now going on, and takes occasion to add a sketch of the history of the institution. It seems that the repairs are of a radical character, but it is expected that they will be finished by the middle of September. The *Sentinel* gives the list of teachers as follows: John Moffett, M. D., emeritus professor of obstetrics; Joseph Eastman, M. D., LL. D. (president), professor of diseases of women and abdominal surgery; John A. Sutcliffe, A. M., M. D., professor of surgery and of genito-urinary and rectal diseases; Samuel E. Earp, M. S., M. D. (dean and secretary), professor of materia medica, therapeutics, and clinical medicine; Allison Maxwell, A. M., M. D., professor of the principles and practice of medicine, physical diagnosis and sanitary science; E. J. Brennan, M. D., professor of obstetrics and clinical midwifery; John B. Long, M. D., professor of descriptive and surgical anatomy; John F. Barnhill, M. D., professor of physiology; S. E. Crose, A. M., M. D., professor of medical chemistry, toxicology, and medical jurisprudence; William B. Fletcher, M. D., professor of diseases of the mind and clinical medicine; William H. Thomas, M. D., professor

of diseases of the nervous system; Green V. Woolen, A. M., M. D., professor of rhinology and laryngology; William M. Morgan, M. D., professor of fractures and dislocations and of orthopædic and clinical surgery; H. O. Pantzer, M. D., professor of clinical gynecology and the principles of surgery; Louis Burckhardt, M. D., professor of operative and clinical midwifery; Albert E. Sterne, A. M., M. D., professor of the anatomy, physiology, and pathology of the nervous system and of clinical medicine; Minor Morris, A. B., M. D., professor of pathology, dermatology, and bacteriology; Levi L. Todd, M. D., professor of clinical medicine and lecturer on gastric and pulmonary diseases; John L. Masters, M. D. (treasurer), professor of diseases of the eye and ear and of histology; John A. Lambert, Ph. G., M. D., professor of diseases of children; Joseph Rilus Eastman, B. S., M. D., adjunct professor of physiology; Thomas B. Eastman, A. B., M. D. (assistant secretary), adjunct professor of anatomy and assistant in diseases of women; Charles O. Durham, M. D., demonstrator of anatomy; Thomas E. Courtney, M. D., assistant demonstrator of anatomy; Martin V. B. Newcomer, M. D., lecturer on railroad surgery; H. G. Gaylord, M. D., demonstrator of bacteriology; S. P. Scherer, M. D., assistant in practice of medicine; F. C. Tinsley, M. D., assistant in materia medica; Leonard Bell, M. D., assistant in pathology; Amasa Mullan, M. D., demonstrator of chemistry; Amelia R. Keller, M. D., clinical assistant in clinical gynecology; J. J. Booz, M. D., assistant in chemistry; John Kolmer, assistant in physiology.

**The Practice of Pharmacy as a Liberal Profession.**—The *Journal of the American Medical Association* for July 11th contains an address which was delivered by Dr. F. E. Stewart, of Detroit, at the annual meeting of the American Medical Association, of which the following is an abstract: If pharmacy is a department of science, its practice is a medical art. It therefore follows as a natural sequence that pharmacy must be regarded in the light of a medical specialty, and the pharmacist is under the same obligation to science, to the profession, and to suffering humanity as the physician.

Medicine, says Dr. Stewart, is a liberal profession. It is distinguished from a mercantile pursuit in that its primary object is service to humanity. Medicine owes its high position among the vocations of men to its philanthropic aim, seeking in every way to relieve and prevent human suffering, devoting itself to original research, and publishing its results for the benefit of science, constantly sacrificing self-interest to aid others, and neglecting, for philanthropic reasons, to take advantage of many opportunities for gain.

If this is true, he says, then pharmacy can never be recognized as a liberal profession until it becomes part of the medical profession, for it can not, from the very nature of things, become a profession by itself. Pharmacy is directly dependent upon therapeutics, and is like a body without a soul when divorced therefrom.

Pharmacy can find its higher advancement, not by catering to an unenlightened public, unfitted to appreciate it either from a scientific or professional standpoint, but by working with physicians to a common end, that end being the promotion of progress in pharmacology as a science, the advancement of pharmacy as a profession, and the study of means to prevent and alleviate human suffering. By serving this end pharmacy will find its true position among the liberal professions.

As a trade, Dr. Stewart thinks, pharmacy would seek to create a fictitious demand for drugs by exaggerating their importance as curative agents, thus pandering to the morbid tendency of the public to dose itself for real or imaginary diseases. As a profession it will join with the medical profession in efforts to relieve the public of the necessity of taking medicine. Co-operation between the physician and pharmacist is absolutely indispensable to the advancement of pharmacologic science, for, as already said, neither therapeutics nor pharmacy as science or practice can exist alone.

The science of medicine professes to exhibit what is actually known, or may be learned, in the forms of exact observation, precise definition, fixed terminology, classified arrangement, and rational explanation. To promote the progress of the science of drugs it is therefore necessary for both professions to publish the results of their discoveries for the benefit of science. It is just as reprehensible for physicians to neglect the publication of the results they obtain from the use of drugs, or their preparations, as it is for the pharmacist to restrain the knowledge of the same from general use, by means of secret formulas, protected from legitimate competition by fanciful names which are registered as trade-marks at the patent office in Washington. How, asks Dr. Stewart, can the demands of science be satisfied unless the knowledge of every substance used in medicine, together with its method of preparation and application, is published and its manufacture and sale open to legitimate competition?

Dr. Stewart calls attention to the position and responsibility of the physician and pharmacist in relation to the pharmacopœia. On the analysis of twenty-seven thousand prescriptions recently made, he says, by Professor Patch, president of the American Pharmaceutical Association, it was shown that the pharmacopœia was sadly neglected by physicians. Only seventeen vegetable drugs were prescribed, and more than a hundred drugs of vegetable origin neglected. Ten metals were honored, but more than ten were left out in the cold. In fact, the entire materia medica comprised in these twenty-seven thousand prescriptions consisted of the following drugs and preparations:

Acetanilide; antikamnia; antifebrine; antipyrine; aristol; phenacetine; arsenious acid; boric acid; carbolic acid; hydrochloric acid; salicylic acid; sulphuric acid, and twenty-five other kinds of acids; aconite and its preparations; ammonium salts, chloride, carbonate, bromide, etc.; belladonna, its preparations and alkaloids; bismuth salts, principally the subnitrate; brandy; camphor and its preparations; cascara sagrada and its preparations; chloroform, its preparations and combinations; cinchona and its preparations, combinations, and alkaloids; digitalis and preparations; gentian and preparations; ginger and preparations; glycyrrhiza and preparations; hyoscyamus and preparations; iodine and preparations; lead salts and preparations; mercury, its salts and preparations; nux vomica, its preparations and alkaloids; potassium salts and preparations; rhubarb, its preparations and combinations.

In this study of 27,000 prescriptions from nineteen drug stores distributed in Chicago, Philadelphia, Bayonne, N. J., Boston, Washington, Baltimore, Denver, San Francisco, New Orleans, Cincinnati, and St. Louis, 11.25 per cent. were proprietary articles, not including many elixirs, pills, tablets, fluid extracts, etc., which were of specified manufacture.

An analysis of 10,000 prescriptions, made by the

committee on revision of the *United States Pharmacopœia* of the Illinois Pharmaceutical Association, shows that in 2,613 prescriptions, or about a fourth of the whole number, proprietary remedies were prescribed. Many proprietary articles are of the greatest value, says Dr. Stewart. They are often the products of manufacturing houses provided with the very best facilities of manufacturing. Many of them represent the researches of the most learned chemists, extended over years of careful investigation. In fact, it is fair to assume that some of our proprietary medicines advertised to the medical profession in the medical journals represent the van of progress in pharmacy. To be sure, some of them are of comparatively little value, and should find a place in the lumber room with the trash in company with much of what is now official in the pharmacopœia.

Assuming, says Dr. Stewart, that the proprietary medicines referred to are valuable pharmaceutical preparations, it is evident that a place should be found for them in the next revision of the pharmacopœia. It is equally evident that they can not be admitted as proprietary medicines, unless the medical profession shall indorse a system which withholds from general use that entire class of preparations. Such an indorsement, he thinks, on the part of the medical profession would be a complete surrender of the altruistic ideal that distinguishes the practice of medicine as a liberal profession and an indorsement of a most dangerous form of commercialism.

From what has been said it is very evident that affiliation between physicians and pharmacists is of the first importance in promoting progress in the knowledge of pharmacology, in improving our pharmacopœia, and in rescuing medical and pharmaceutical practice from the grasp of the proprietary-medicine trade which is now encroaching upon the domain of the pharmacist and the physician. It may be said that there are unsurmountable obstacles to affiliation between physicians and pharmacists. They are at war with one another everywhere. Physicians, says the author, charge that pharmacists prescribe over the counter, and that the practice is unjustifiable, as they are not competent to do so either by education or training, and it is an unwarrantable interference with the physician's prerogative to treat the sick. But the pharmacist can urge with equal propriety that the physician is not competent to compound and dispense his own medicine, and that for him to do so is an unwarranted interference with the prerogative of the pharmacist. There is a great deal of difference between the deep blue sea and the dry land, although one overlaps the other on the beach, and it seems to Dr. Stewart that this question of interference between the physician and the pharmacist is something of the same nature. Both may wade with impunity in the shallow waters along the shore, and do no real harm to each other, or to the public at large. But there are depths in pharmacy capable of drowning the venturesome physician; and the pharmacist who attempts to climb the high mountains of diagnosis and treatment is sure, sooner or later, to fall and break his neck. Yet in some countries these prerogatives are protected by law, and both physician and pharmacist must keep on his own side of the fence.

But, say the physicians, we can never unite with pharmacists until they no longer renew our prescriptions without our authority. It is damaging to our reputation and purse, and a very unfriendly act to say

the least about it. But physicians lose sight of the fact that both professions are servants to the public, and if the patient is refused the privilege of having his prescription renewed, he will seek another physician and another pharmacist. Not until the public is educated to appreciate the necessity of consulting the physician before renewing prescriptions will the prescription-renewing nuisance be abated. Pharmacists, to a great extent, are powerless in the matter, and the medical profession has done much to foster the abuse by prescribing ready-made nostrums; so the fault is not entirely with the public either.

Physicians complain bitterly that pharmacists sell "patent" medicines and thus make themselves the agents of the nostrum monger. But the proprietary-medicine business owes its present standing in the community more to the medical profession than to the pharmacist. More than ten per cent. of the medicines prescribed by the physicians in the United States are so-called patent medicines, and the physician is just as much to blame for prescribing them as the pharmacist for selling them. Dr. Stewart can see no good reason why harmony can not be restored between the pharmacist and physician. Once both are in touch and working for a common object, many of the evils now complained of will rectify themselves in time, and the public will soon feel the influence of a united profession, and respect the calling of both physician and pharmacist more highly in consequence.

**The Mississippi Valley Medical Association.**—The secretary, Dr. Hanau W. Loeb, announces that the date of the meeting has been changed to September 15th, 16th, 17th, and 18th, in order to permit the members and their families to take the opportunity accorded by this change to make a tour through the Yellowstone Park. Prominent resident members of the association in St. Paul and Minneapolis are perfecting plans for the special Yellowstone Park excursion trip, to leave on the evening of September 18th, arriving in Mammoth Hot Springs, in the Yellowstone Park, about noon on the following Sunday, and devoting the following five days to the wonders of this remarkable region, returning to St. Paul on Sunday, September 27th. The cost of the trip, including all expenses west of St. Paul, will be announced in due season, but it is stated that the figure will be a very favorable one. This announcement is made so as to give members the opportunity of making their plans in advance to join the party. It is desirable that there be a party of a hundred or more, in order to obtain the benefit of the special train service in both directions. It is urged that all members who desire to join the party should send their names to Dr. C. A. Wheaton, chairman of the committee of arrangements, 351 North Washington Street, St. Paul, at as early a date as possible.

**A Ceylon Physician killed by a Snake.**—Universal regret will be felt in medical circles, says the *Indian Medical Record*, at the death following snake-bite of Dr. Arthur Stradling, who has for many years past devoted himself to the study of Indian and Ceylon snakes and their poisons, with a view to the discovery of an antidote. He had, as he imagined, rendered himself almost proof against the venom of snakes, but in this belief he was mistaken, for while he was conducting an experiment recently with one of the deadliest snakes of Ceylon the reptile bit him, and death followed within a few hours.

## Original Communications.

### MALIGNANT PUSTULE OF THE FACE.\*

By JOHN F. ERDMANN, M. D.

PATRICK McD., aged fifty years, married, Ireland; occupation, wharfman—unloads ships. This patient says that while smoking a pipe, about the 1st of March, a spark lit on his right cheek and left a small red spot, but gave him no discomfort. About eight days following he noticed a small pimple on his cheek at about the same place that the spark had burned him. On March 16th a friend called his attention to a running sore on his cheek; at this time, he says, the pimple had become a spot of the size of a silver quarter, had angry edges, and a black centre to it; that the black looked

like a scab, while on the edge there were numbers of blisters. On the 18th he came to Gouverneur Dispensary and was treated with acetanilide; the area could just be covered with a fifty-cent piece, had a black centre, and numerous vesicles containing serum and sero-pus about the edges. Redness and swelling extended to the eyes.

I saw him on the 19th, at which time the central slough was fully as large as a silver fifty-cent piece, and the vesicular edges extended fully an inch about the slough. The eye was almost closed, and the forehead on the right side oedematous. Pulse was 78 to 82; temperature and respiration normal; patient in excellent condition and at work during the day. Suspecting anthrax, I obtained some of the serum and blood, and had it examined by the board of health bacteriologists, who reported the specimen to contain numerous anthrax bacilli.

The ulcer was dressed with a 1-to-40 carbolic solution, and the patient allowed to go out.

Under the carbolic lotion the swelling disappeared in forty-eight hours, and no further extension of the ulcer was observed. At this time, March 21st, almost all the slough was cut off and the actual cautery applied over the entire area. Upon cutting off the slough, which was hard and dry and could be pared like leather, numerous small foci of yellow material, resembling pus, were exposed. Cultures from these parings gave no evidence of the anthrax bacillus. From this time on the patient has made a rapid recovery.

I present him to you to-night with a healthy, healing surface, and, at the same time, present you with a photograph as he appeared on the day of cauterization. There was no history of handling wool or hides during the time of the burn and the development of the pimple.

### X RAYS IN THE DIAGNOSIS OF FRACTURES

By W. H. HANCKER, M. D.,

FARNHURST, DEL.

H. H., aged thirty-five years, of Newcastle, Del.; weight, two hundred and twenty-five pounds; during an attack of somnambulism on the morning of June 11, 1896, fell a distance of four feet while descending the stairs. He alighted in a sitting posture, with his hand under him, and in a state of pronation, his whole weight resting upon his right wrist.

His family physician, Dr. David Stewart, Jr., was called about six hours later. Owing to the extreme stoutness of the patient and the excessive tumefaction and tenderness around the injured wrist (the antero-posterior diameter being about three inches), a positive diagnosis

was impossible without the aid of an anæsthetic, which the patient strenuously opposed. Acting under the supposition that he had a Colles's fracture to deal with, Dr. Stewart applied the proper splints. Two weeks after the injury the patient was brought to the Delaware State Hospital, Farnhurst, when the accompanying Röntgen picture was made, showing conclusively that the case was one of fracture, and that the apposition of the parts was perfect.

\* Read before the Society of Alumni of Bellevue Hospital, April 1, 1896

The fracture itself is not an extraordinary one, but it is of some satisfaction to the medical profession to know that we have at our hands an apparatus that will aid us when we are in doubt, especially in cases when an error in diagnosis is liable to be disastrous—as is so often the case in fractures in and around this intricate part of our osseous system.

## THE TREATMENT OF FRACTURES AND DISLOCATIONS OF THE ELBOW JOINT.

A NEW SPLINT.

By E. Z. BOWER, M. D.,  
PHILADELPHIA, PA.

PROFESSOR S. D. GROSS has said "I know of no fractures or dislocations which I approach with more doubt and misgiving than those of the elbow joint. I know of none more liable to be followed by severe inflammation, effusion, ankylosis, and deformity. Even in the most simple forms, where the treatment has been skillfully conducted, there is great risk of an unfavorable result. At all events, a long period of time will be sure to elapse before there will be anything like good use of the articulation." In speaking of treatment, Professor Gross says: "Passive motion is to be commenced at the end of two weeks." In consulting the works of Erichsen and Hamilton and the late and exhaustive work of Dennis on *Surgery*, the teaching is found to be the same in regard to passive motion. The teaching of the *American Text-book of Surgery*, however, is quite different. In treating of fractures involving this joint, this authority states that daily forcing of the joint is more likely to do harm than good. In treating of dislocations, the same authority again states that passive motion to prevent ankylosis is not required and is likely to do harm. The cause of ankylosis and deformity in this class of injuries is the pouring out of callus and formation of adhesions. Early forcible motion of the joint will cause some slight movement of the broken fragments and a restripping up or stretching of the torn periosteum and ligaments, with an increased outpouring of callus. Certainly any one who has used passive motion in such injuries has not failed to notice the increased inflammatory symptoms following extensive or forced movement, which plainly indicate that something unfavorable to rapid recovery and injurious to final result has taken place inside the joint. On the other hand, to make no motion at all would be to allow the callus thrown out after the primary injury to undergo bony formation and obstruct movement, and to invite extensive and strong adhesions. The writer, being thus strongly opposed in front and flanked in the rear, was led to make use of an anterior splint with a hinge joint at the elbow, such as are commonly sold in the shops and recommended by teachers and authors. In one case in

particular, being a dislocation of both bones of the forearm backward, complicated by fracture of the coronoid process of the ulna and internal condyle of the humerus, the writer found that it was impossible with the ordinary hinged splint to bring the arm to an angle of less than ninety degrees, because of pressure being made in the bend of the elbow. This led to the improvising of the following (shown in cut) appliance, which removes all pressure from the joint, yet holds it firm, the elbow being free from dressings and fully exposed, so that any

displacement of fragments or untoward symptoms may be detected and rectified without removing the splint, while the forearm can be flexed to forty-five degrees and extended to a hundred and seventy; this being done in the course of each week by a few turns of the thumbscrews several times a day, the change taking place so gradually and continuously that the bony, ligamentous, and periosteal fragments are undisturbed and increased throwing out of callus is avoided, while that due to the primary injury is slowly broken up and as rapidly absorbed, as are also the adhesions, thus insuring a rapid and satisfactory result. The splint consists of two Y-shaped pieces of light wood united by the diverging arms of the first Y, or forearm piece, being inserted into the arms of the second Y, or arm piece. Each piece has fastened to it, with screws, at right angles, about three inches from the diverging arms, a piece of flat iron which projects an inch to the outside or left for left arm and right for right arm. The lower iron crosspiece has attached to its projecting end an iron rod ten inches in length, upon which a thread is cut throughout, and not for a part of its length only, as the cut shows. The upper iron crosspiece has an oblong opening in its projecting end through which the rod is inserted. Two thumbscrews, one anterior, the other posterior to this, hold it firm and allow the angle to be changed at will.

**The Use of Salophene in Chorea.**—Dr. Luigi Cappelleri (*Riforma medica*, 1896, No. 129; *Therapeutische Wochenschrift*, July 19, 1896) reports a case of chorea minor following influenza in a girl, eleven years old, with nervous tendencies. She could not take Fowler's solution, because it deranged her digestion. Salophene was given in doses of five grains six times a day at first, subsequently increased to seven grains. This was continued for ten days without digestive disturbance. As the chorea had become mitigated, the doses were then reduced to what they had been at first and given for ten days more, at the end of which time the chorea showed itself only on attempts at voluntary movement of the arm and soon disappeared entirely.

## TWO CASES OF TRAUMATIC ANEURYSM TREATED BY LIGATION AND EXTIRPATION OF SAC.\*

1. FEMORAL (ARTERIO-VEINOS).

2. DORSALIS PEDIS.

By JOHN T. HOWELL, M.D.,

NEWBURGH, N. Y.

I AM somewhat tardy in reporting the following histories of two cases of traumatic aneurysm; but they have seemed to me to be sufficiently unique to merit your attention; and the time elapsed makes their recurrence the less probable and the records complete:

**CASE I.**—C. S., aged thirty-six years, a carpenter. On October 5, 1894, while standing with his right foot upon a chair and endeavoring to cut out a pasteboard pattern, which was resting upon his thigh, he accidentally stabbed himself there with the small blade of the jack-knife he had been using.

A stream of blood spurted from the wound, which was over the course of the femoral vessels and nearly halfway down the thigh. He became faint, but the hemorrhage was checked by means of a tight bandage applied by some member of his family, and when Dr. Brownell, of Walden, saw the case soon afterward the bleeding had entirely ceased.

The bandage was left in place until the next morning, when, upon its removal, no hemorrhage followed, and there was no evidence of subcutaneous bleeding. A dressing was applied, and the patient told to keep quiet in bed. He, however, walked about some during the following three days, and then began to have pain and considerable swelling in the region injured. The doctor was again called and then detected signs of aneurysm. Firm pressure was kept applied for a week without controlling its growth.

On October 17th I first saw the case with Dr. Smith Ely, of Newburgh, and the diagnosis of traumatic aneurysm was readily confirmed in the large, pulsating, expansive tumor felt with its thrill and bruit. These symptoms were controlled by pressure upon the femoral artery above.

A tourniquet having been applied, an incision was made down to the sac, much of which had formed outside the vessels by means of the surrounding soft parts and new connective tissue. In size it nearly equaled a large orange. The clots with which it was filled having been removed, it was found that the femoral artery and vein had both been perforated by the stab wound at about the junction of the upper and middle thirds of their course, where the vein lay behind the artery. As the vein had also been perforated and was dilated, it was decided to ligate both of the vessels above and below, and excise the intervening portions with the rest of the sac. Silk ligatures were applied and all but the most adherent portions of the aneurysms dissected out. The wound was then partially sutured and packed with iodoform gauze.

The usual dressing having been applied and the limb enveloped in cotton, it was kept elevated and surrounded by hot bottles. The circulation remained good and after forty-eight hours the heat was gradually withdrawn. No unfavorable symptoms followed and by the

fourth week the wound had fully healed. Since that time the patient has experienced no circulatory or other disturbances as a result of the operation and has continued in good health.

**CASE II.**—F. W., aged thirty-four years, flagstone layer (blind). This accident occurred July 12, 1895, by means of a crowbar falling a distance of three feet and striking the instep of his right foot. At first he experienced a great deal of pain, and after walking a little way removed his shoe and found considerable swelling. Next day he was able to walk about some, but finally called in a physician. When I first saw the case, ten days later, examination showed a tender, slightly reddened swelling of the instep and outside of the ankle, which did not prevent walking about the house. No expansive pulsation or sign of aneurysm was then detected. Bandaging and rest reduced the swelling somewhat; but this became irksome and the patient tried again to use his foot. This increased the swelling and pain, and rest was again enjoined, with some encouragement for a couple of weeks, when the swelling began to grow much larger and slight expansive pulsation was felt which could be controlled by pressure upon the anterior tibial artery above. The tumor was of a fusiform shape, extending along the course of the dorsalis pedis artery for two inches and a half below the annular ligament. The bruit was plainly distinguished and there was a noticeable increase in temperature over the swelling.

The increase in size of the tumor was plainly seen day by day, and on August 15th it was decided best to operate.

An incision was first made, thoroughly exposing the aneurysmal sac, which had been almost entirely formed of the walls of the dorsalis pedis artery and extended fully up to and beneath the annular ligament. A ligation was accordingly made of the anterior tibial artery, in its lower third, which entirely controlled pulsation of the aneurysm. Another ligature was applied to the dorsalis pedis below the aneurysm, and all but the most adherent portions of the sac dissected out. In cutting away its upper part an artery of considerable size was wounded and bled very freely. This vessel lay on the outer side of the proprius pollicis tendon, just beneath the annular ligament, and apparently ran across the upper neck of the sac. It was noticed that pressure upon the posterior tibial artery controlled the bleeding, and the vessel was supposed to be an enlarged anastomotic branch.

A half-inch incision into the lower edge of the ligament was necessary before the vessel could be secured. The wound was partly sutured and packed with iodoform gauze, and then the usual dressings and a splint were applied. The iodoform strip was removed within forty-eight hours, and the wound was completely healed in about two weeks. Recovery was uneventful, and no after difficulties arose.

The man, although blind, is still laying walks.

**Ohio Midwives.**—"The Ohio Medical University has a department of midwifery, the curriculum of which extends over a period of two years, and includes instruction in anatomy, physiology, chemistry, materia medica, embryology, obstetrics, diseases of pregnancy, diseases of infancy, therapeutics, bacteriology, and clinical obstetrics. This is a move which the city of New York might do well to take cognizance of, with a view to the inauguration of a system of obligatory instruction for its large numbers of uneducated and ill-trained midwives."—*American Medico-Surgical Bulletin*.

# DISCUSSION OF PULMONARY HÆMORRHAGE. ÆTIOLOGICAL AND PATHOLOGICAL CONDITIONS.\*

By R. J. CARLISLE, M. D.

THE diseases or conditions in which pulmonary hæmorrhage may possibly occur are so many and varied, and many of them so rare, that it seems to me impracticable to do more than mention many of them.

A discussion on pulmonary hæmorrhage (I mean a discussion of a practical kind) does not include a consideration of hæmorrhage in general, or of those general blood states, whether congenital or acquired, in which hæmorrhage from any or all mucous surfaces is apt to occur. When we recognize the fact that, in the vast majority of cases if not in all, the pathological changes leading to pulmonary hæmorrhage are either in the line of arterial or venous hyperæmia or of degeneration or destruction of the walls of the blood-vessels, and furthermore, that these conditions are found in those few diseased states to which the greatest number of cases of pulmonary hæmorrhage may be referred, it seems that a discussion limited to hæmorrhage in these cases will serve every useful purpose.

Pulmonary hæmorrhage is not always accompanied by hæmoptysis, but it is so accompanied in the majority of instances. Hæmoptysis, in its proper restricted sense, refers to hæmorrhage from the smallest subdivisions of the bronchial tree or from the lung tissue itself.

To narrow the discussion to practical limits, therefore, it may be said that pulmonary hæmorrhage is most frequently due to tuberculosis, or to cardiac disease, in conjunction sometimes, in either case, with distinct changes in the coats of the blood-vessels; or this latter condition itself may be the principal predisposing cause. A special exciting cause may or may not exist.

In cases in which tuberculosis is the responsible condition, many times hæmoptysis precedes the onset of other diagnostic symptoms, or, indeed, of any symptoms, by a variable length of time, and may in other instances be immediately followed by cough, dyspnoea, and rise of temperature. What relation does the hæmorrhage bear to the tuberculosis? What is the source? The hæmorrhage may come from the capillaries or the arterioles of the bronchial or pulmonary arteries, the blood extravasating into the bronchioles and alveolar passages. It is in the walls of these bronchioles and alveolar passages that the tuberculous changes usually first begin; and while in the midst of the tuberculous new growth the vessels are finally obliterated, yet early in the process the changes in the vascular walls admit of hæmorrhage either by diapedesis or by actual rupture. Or the hæmorrhage may come from the vessels immediately surrounding the diseased mass, in areas of collateral hyperæmia, whether this hyperæmia is inflammatory

in origin or due to the increased pressure produced by the obliteration of vessels above referred to.

Another condition which may be present, either alone or in conjunction with these, is ulceration and destruction of arterial twigs by a caseating process extending from a diseased bronchial gland.

The pathological changes above enumerated in many cases cover so small an area that it is not possible to discover them by physical signs or by any symptoms either local or general.

The amount of blood lost is usually not large. It fills the air-passages in the immediate vicinity, and the major part is usually immediately expectorated, what remains being discharged in the form of clots during the course of the next few hours or days. Usually, therefore, no changes, or very slight changes, are produced in the surrounding lung tissue by the extravasated blood; even if some remains it is disintegrated and absorbed. However, inflammatory changes in the form of a broncho-pneumonia may supervene in the infiltrated lung tissue which, in turn, goes on to caseation, and the tubercular process is further advanced.

It is well known that cases in which hæmoptysis occurs early usually do well—better, in fact, many times, than cases in which this symptom has not occurred. Perhaps the fact that following an hæmoptysis the bacilli are markedly diminished or even absent from the sputum for some time may explain the slow advance of these cases.

The cases of hæmoptysis which are said to be innocuous in that no further symptom of related disease ever arises—cases which are stated by some to be of no significance—may here be referred to. No case of hæmoptysis should be looked upon as without significance; even when unaccompanied by other signs, it should never be considered otherwise than as a serious symptom. It loses its significance only after the lapse of years of freedom from symptoms. Should hæmoptysis occur in the case of any one of us, no matter how good the state of health might at the time apparently be, it would be considered by that one as of very great significance. And, furthermore, any life-insurance examiner in considering the question of placing a risk on the life of such a patient, even if he is able to find no evidence of tuberculosis or cardiac disease, if he accepts the risk adds a little something to the premium to make sure, and he is justified in so doing.

In a case of unaccompanied hæmoptysis, as between tuberculosis and cardiac or vessel disease, the younger the patient the more likely is it to be due to the first, and, on the contrary, the older the patient at the time of its first occurrence, the more likely is it due to cardiac or vessel disease. And, further, the longer the time that has elapsed after the date of the hæmoptysis, without recurrence, the more probable is it that it was due to tubercular disease and not to either of the other causes.

\* Read before the Society of Alumni of Bellevue Hospital, April 1, 1896.

In endeavoring to determine the actual significance of hæmorrhage in these cases, in addition to the matter of time, the two symptoms that should receive the first attention are cough and dyspnœa, however slight.

To return to tuberculosis: pulmonary hæmorrhage, occurring after the onset of other symptoms of pulmonary disease, is due in the vast majority of cases to the like pathological conditions. In rapid tuberculosis it is very infrequent; it may occur, however, even in the acute ciliary variety. In caseating pneumonia, with rapid cavity formation, it has, as a rule, the same features. It is said to be rarely the result of the excavating process; perhaps, as Rasmussen declared, because going along with this process is the obliteration of the blood-vessels.

Pulmonary hæmorrhage, however, is not infrequently present in the chronic type after the development of cavities. Rasmussen, who was one of the very first to demonstrate the source of hæmorrhages in many of these cases, believed that the blood came from cavities with rigid walls, which were due in part, at least, to bronchiectasis. It is in these cases that the largest hæmorrhages occur, sometimes proving fatal. They are due to the rupture of arteries running in the bands of connective tissue across the cavity, or to small aneurysms in the cavity walls. In several of the cases reported by Rasmussen, in his first papers concerning these aneurysms (*Edin. Med. Jour.*, vols. xiv and xv), there were degenerative changes in the branches of the pulmonary artery, in the proximal part of it, and in all of them he demonstrated to his own satisfaction that the dilatation was due to narrowing of the artery beyond the aneurysm by contraction of tissue and destruction of vessels, thus increasing the blood pressure and also the lack of support to that side of the vessel wall which presented toward the centre of the cavity. The opening in the arterial wall in every case was valvelike, this explaining the gradual loss of blood in some cases. Rasmussen thought all the cases of hæmorrhage in chronic ulcerative tuberculosis, or, at any rate, all the fatal cases in which the loss of blood is great, are due to these aneurysms, and that these were not always found because of the failure to look carefully enough, and reports an autopsy to show that on first view, because of the presence of cavities in which there was no blood, the hæmorrhage looked to be bronchial in origin, yet, after several sections, a cavity was found near the apex of the lung, posteriorly, of small size, inclosing a small aneurysm. Pulmonary hæmorrhage is rare in cases of tuberculosis in children, and particularly under the age of seven years. This is explained in part by Rasmussen, by the fact that bronchiectatic cavities are rare in the varieties of pulmonary tuberculosis seen in children, the cavities due to destruction of lung tissue being unaccompanied by hæmorrhage in a child, and another reason for this infrequency of hæmoptysis may be that children, as a rule, do not expectorate. Instances of hæmorrhage in chil-

dren described in the literature are, as a very general rule, profuse.

Pulmonary hæmorrhage is a result of those changes in the heart which obstruct the flow of blood through the lungs, or permit of the formation of thrombi in the right auricle or ventricle. It usually gives rise to hæmoptysis.

It is due in the majority of cases to valvular lesions and their concomitants, and usually to mitral lesions. It occurs earlier and more frequently in connection with mitral stenosis than with any of the others. Myocardial degeneration and pericarditis may give rise to it. The latter disease may bring it about by pressure put upon the left auricle in cases of large effusion of liquid, or by the effects upon the heart muscle of the adhesive form. Hypertrophy of the right heart in conjunction with obliteration of pulmonary capillaries, as found in primary emphysema, may give rise to it, and hæmoptysis is therefore seen in some cases of that disease.

Hæmoptysis is, in cases due to cardiac difficulty, small in amount, and it is apt to recur at frequent intervals. There may be a considerable number of capillary hæmorrhages without hæmoptysis.

The pathological conditions present in these cases giving rise to hæmorrhages are: brown induration of lung, hypostatic congestion, and hæmorrhagic infarctions. Hæmorrhagic spots, occurring throughout the lungs in these cases, are ascribed by some to embolic effects. Hamilton (*Liverpool Med.-chir. Jour.*, 1883, vol. iii, No. 5) denied that they were embolic in origin but purely hæmorrhages from bronchial or pulmonary radicles, even when the areas filled with blood are wedge-shaped. He maintained that this shape was due to the filling up of a whole lobule with blood, and that lobules near the pleural surfaces always would be wedge-shaped when filled with blood, and that these areas when near the root of the lung were never wedge-shaped; and, further, that it was unreasonable to suppose that so many emboli would be set loose at one time as would account for the number of so-called infarcted areas.

Pulmonary apoplexy is a term used particularly by French writers, and others following them, rather indefinitely, but should be restricted to that condition due to a large hæmorrhage into the structure of the lung, destroying the parenchyma over an area varying in extent, and which may involve a whole lobe, such as may follow, for example, the rupture of a thoracic-aortic aneurysm into the lung directly. Hypostatic congestion of the lung and the pouring out of blood into the pulmonary spaces, with or without rupture, occurs often in connection with brain and cord injuries, and may be accompanied by hæmoptysis, though rarely.

Degenerative change in the blood-vessel walls has been shown to be an element in tubercular cases sometimes, and also in cardiac cases. It may of itself be the predominant cause. Arteriosclerosis affecting the pul-

monary artery is not frequently seen, perhaps, because it is rarely looked for. A few years since (1889), Sir Andrew Clark reported some cases of recurring hæmoptysis in patients over fifty or sixty years of age, afflicted with arthritic change, and whose lungs showed the signs of emphysema, in which, on autopsy, there were found in and near the hæmorrhagic areas marked patches of senile emphysema, and on microscopical examination the pulmonary capillaries leading to these parts were found to be degenerated, no other cause for hæmorrhages being present.

To refer to some of the infrequent causes of hæmorrhages: Bronchitis is sometimes accompanied by hæmoptysis, particularly that infrequent form, the fibrinous variety. The casts of tubes should be differentiated from the coagula of blood, which may simulate them. The fact remains that bronchitis, when accompanied by tubercular changes is more apt to be associated with hæmoptysis than when not so accompanied.

Malignant disease and hydatid disease of the lung also are causes giving rise to somewhat characteristic forms of hæmoptysis. This latter disease is said by Germain Sée to give rise to blood spitting as frequently as tuberculosis itself; but this disease has a limited area of distribution.

Hæmoptysis may be a vicarious hæmorrhage. Several well-authenticated cases are on record. This form may occur during the amenorrhœa of pregnancy and lactation, and cease when the normal flow is re-established.

Various exciting causes of hæmoptysis might be referred to were there time—such as excessive exertion, coughing, public speaking, etc. In the predisposing conditions of pulmonary hæmorrhage recited above, the immediate cause may be some such circumstance as one of these.

In mountain-climbing hæmoptysis is sometimes seen, and said to be due to the rarefaction of the atmosphere. Certain it is that it needs much less exertion to act as an exciting cause when the exercise is combined with a changing atmospheric pressure. The hæmorrhages which occur in caisson disease result from a too rapid change from a high pressure to a low one.

## THE TREATMENT OF PULMONARY HÆMORRHAGE.\*

BY JOHN WINTERS BRANNAN, M. D.,  
PHYSICIAN TO BELLEVUE AND THE WILLARD PARKER HOSPITALS.

THE subject assigned to me this evening covers so broad a field that I shall not attempt to deal with it exhaustively, but shall limit myself to certain general considerations. Hæmorrhage from the lungs takes place in a large number of diseases and pathological conditions, but it is chiefly in connection with pulmonary

tuberculosis and obstructive disease of the heart that it calls for active therapeutic measures on our part. Many forms of hæmoptysis do not require special treatment, and in all varieties direct treatment of the hæmorrhage should be promptly followed by treatment of the disease to which it is due.

In hæmoptysis occurring in pulmonary tuberculosis the general indications for treatment are evident. The bleeding comes either by diapedesis from the smaller vessels of the bronchial or pulmonary mucous membrane, or by rhexis from a ruptured or eroded branch of the pulmonary artery. The former condition is probably the source of the hæmoptysis which occurs early in the disease, when there may be no physical signs whatever in the chest. It is customary to speak of this form of pulmonary hæmorrhage as bronchorrhagia, and to ascribe it to a congested area of the bronchial mucous membrane. There is, however, so far as I know, no clinical or pathological evidence to prove that such a localized congestion of the respiratory tract ever takes place, unless there is also an acute inflammatory process present. And yet it is not very uncommon for hæmoptysis to occur in an individual who experiences not the slightest sense of discomfort in the chest, either before, during, or after the event. How, then, are we to account for the hæmorrhage? I believe that pathology furnishes us with an explanation that is sound, and that also explains the ominous significance of the occurrence. According to Delafield and Prudden,\* "Hæmorrhage by diapedesis usually occurs in the smaller veins and capillaries, all the elements of the blood passing out through the cement substance between the endothelial cells. Although no marked morphological changes have as yet been detected which explain this extravasation, it is probable that some change in the nutrition of the walls does occur which renders them more permeable." Ziegler† also states that "under pathological conditions the cement substance between the endothelial cells [of the vessel walls] becomes softened and permits the passage of the red blood-corpuscles." This nutritive change in the walls of the vessels, which permits the extravasation of blood, is, to my mind, only a part of the general lowering of nutrition of the whole organism, by which it becomes less resistant to the invasion of the tubercle bacillus. The hæmoptysis in itself is but a symptom, a warning of the danger which is threatening the individual. This view of the occurrence would explain the rarity with which the hæmorrhage itself results seriously, and also the frequency with which it is followed by the development of tubercular phthisis if its significance is not understood and acted upon.

The foregoing hypothesis also accords with another clinical fact which has been noted by Flint and other observers of large experience with pulmonary tuberculosis,

\* Read before the Society of Alumni of Bellevue Hospital, April 1, 1896.

\* *Pathological Anatomy and Histology*, fourth edition, p. 58.

† *General Pathology*, p. 135.

After an analysis of one hundred and seventy-nine cases of phthisis in which the presence or absence of hæmoptysis was recorded in the histories, Flint concludes as follows: \* "It thus appears that cases in which hæmoptysis occurs show a larger number of recoveries and a notably greater proportion of instances of arrest and tolerance than cases in which hæmoptysis does not occur. Under this aspect, therefore, bronchial hæmorrhage is to be regarded as a favorable event." Again, he says: † "Moreover, it is to be borne in mind in this connection that the chances of recovery, arrest, and notable tolerance in cases of tuberculous disease, as our clinical studies have shown, are greater when hæmoptysis occurs than when this event is wanting." Flint contents himself with thus expressing his opinion of the prognostic import of hæmoptysis and does not offer any explanation of the facts upon which his opinion is based. If our view of the pathology of the hæmorrhage is correct, there would seem to be a twofold cause for the comparatively favorable course of these cases. Regarded as the first recognized symptom of the threatened invasion of tuberculosis, the hæmoptysis should often justly be assigned to the pretuberculous period of the disease. Tubercles may already exist in the lungs, but in many cases they apparently are not present, as shown by the lack of further symptoms or physical signs. Our treatment, therefore, of such cases is really preventive in its character, in that it anticipates and checks in its incipency the development of the disease. When, however, hæmoptysis is wanting, the pulmonary process is usually well advanced before our attention is attracted by the less striking symptoms, such as cough, expectoration, and loss of flesh and strength. The lungs being already the seat of tuberculous deposit, our therapeutic measures meet with but partial success. A second reason for the effectiveness of our treatment of cases characterized by hæmoptysis lies in the fact that it is apt to be more thorough. Bleeding from the lungs is such an alarming occurrence that the patient as well as the physician needs no argument in favor of prompt and radical action. Our advice, therefore, is not only given at a time when it can accomplish the greatest good, but it also usually meets with ready acceptance on the part of the patient and his friends.

The treatment of this form of hæmoptysis follows from what has been said of its ætiology. The hæmorrhage itself usually requires little direct treatment beyond rest in bed for a few days, with restricted diet, and opium, if necessary, to relieve cough and allay excitement. As soon as the danger of a recurrence of the bleeding appears to be over, all possible measures should be employed to fortify the patient against the development of tuberculosis. A complete change of surroundings is usually required, at least for a time. The patient should take up his residence in a climate which will allow

of his passing a large portion of the day in the open air. If this is impossible, he should be instructed to practise respiratory exercises for the purpose of deepening the breathing and thus improving the pulmonary circulation. The exercises should be especially designed to expand the apices of the lungs. The tubercle bacillus does not thrive in organs which are in full functional activity and whose tissues are nourished by a constant and vigorous blood supply. These respiratory movements not only increase the capacity of the chest, but also have a marked effect upon the general nutrition of the patient. Deeper and fuller breathing leads to increased oxygenation of the blood. The appetite and digestion are improved, and the patient is enabled to assimilate more food. I have seen patients take with benefit four to five glasses of milk a day, in addition to three good meals, under the stimulating impulse of these so-called pulmonary gymnastics. Strychnine, iron, cod-liver oil, and other tonics are all of value in these cases, but I desire to lay especial stress upon the hygienic treatment. If the above measures are faithfully and persistently carried out, the patient will often have no further symptoms of pulmonary disease and the initial hæmoptysis may indeed "be regarded as a favorable event."

Hæmorrhage by rhexis, from a perforated artery, usually takes place at a time when the tuberculous lesions in the chest are more or less advanced. It demands, as a rule, much more energetic treatment than the form just considered. Our first aim is to quiet the action of the heart and to lower the blood pressure in the pulmonary circulation as much as possible. Absolute rest in bed must be enforced, with avoidance of conversation and all excitement. A hypodermic injection of morphine at this time promotes calm of both mind and body. If the pulse be full and strong and the hæmorrhage profuse and persistent, ligatures may be applied to the four extremities to prevent the blood reaching the pulmonary circuit. Other means to accomplish the same end will readily suggest themselves, such as the employment of purgatives and emetics. The induction of vomiting seems rather a heroic measure, but it will often stop a hæmorrhage most effectually. The food should be cold and taken in small quantities at frequent intervals to attract blood to the alimentary canal.

Of the direct cardiac sedatives I have always preferred aconite. Physiological experiment and clinical evidence unite in its favor. Andrew \* has shown in the Harveian oration of 1890 that in animals aconite produces a fall in the pressure in the pulmonary artery. Although pulmonary vasomotor nerves have never been demonstrated in man, it is probable that they do exist. At all events, judged by its effect in hæmoptysis, it would seem that aconite acts upon the pulmonary circulation in man in a manner similar to its action in animals.

Nature's method of stopping hæmorrhage is by

\* *Phthisis, a Series of Clinical Studies*, p. 107.

† *Loc. cit.*, p. 114.

\* *Brit. Med. Journal*, 1890, vol. ii, p. 942.

coagulation of the blood at the point of bleeding. The blood of tuberculous patients is, however, watery and deficient in clot-forming elements. We have recourse, therefore, to remedies which are believed to increase the coagulability of the blood. Among the drugs recommended for this purpose, my own experience is in favor of gallic acid. Wood has called attention to the greenish hue of the blood expectorated after gallic acid has been taken, thus proving that the drug does reach the circulation. As the hæmorrhage often ceases of itself if the patient remains at rest, it is difficult to determine whether or not our remedies have had any agency in bringing about the desired result. I recall one case, however, in which gallic acid apparently had a marked hæmostatic effect, in spite of the fact that the patient continued at his work.

The case is that of a postman with consolidation at the apex of the left lung, who suffered with rather free hæmoptysis from time to time. He did not wish to give up his occupation, and had tried ergot and other remedies without relief from the spitting of blood. I gave him gallic acid in ten-grain capsules, and he reported later that the hæmorrhages were always promptly checked by its use. This was two or more years ago. I saw him a few weeks since, going his rounds and blowing his whistle, and he told me that the capsules never failed to serve their purpose.

Of all the drugs employed for the relief of hæmoptysis ergot is probably the one in most universal use. I have given it myself in almost every case of internal hæmorrhage that I have been called upon to treat. Its value is, no doubt, dependent upon its power of contracting the small blood-vessels. Inasmuch as ergot produces a decided rise in the blood pressure objections have been raised to its use in pulmonary hæmorrhage. It has also been urged that as the bleeding vessel is generally more or less diseased, it can not respond to the contractile force of the drug, which is expended upon the sound arteries of the body, which it should be our aim to relax and keep full of blood. These objections would seem fatal to the usefulness of ergot in hæmoptysis, were it not that clinical experience furnishes overwhelming evidence in its favor. All observers have seen the hæmorrhage cease almost immediately after a hypodermic injection of ergotine. Undoubtedly in many cases it fails to arrest the flow of blood; probably, in these cases, the walls of the affected vessels have lost all power to contract. When, however, the ruptured artery still contains muscular tissue, the vaso-contracting effect of ergot appears to be greater than its action in raising the blood pressure.

There are many other remedies recommended for the treatment of hæmoptysis, but as this paper does not profess to be complete, I shall not even enumerate them. Aconite, morphine, ergot, and gallic acid respond, in my opinion, to all the indications which we can hope to meet by means of drugs.

When the hæmorrhage has definitely ceased, the hy-

gienic measures already described should be put in force. So long as fever is present, the patient should remain at rest, but not necessarily in bed. I am convinced that patients are often kept in bed much beyond the time when a renewal of the hæmorrhage is the chief danger to be feared. We should always bear in mind that an extension of the tuberculous process is favored by the sluggish circulation and imperfect chest expansion incident to a life of confinement. The patient should be taken out of doors as soon as possible. If his occupation has been of a sedentary nature, it should be changed for one involving an active life in the open air. A change of climate is absolutely essential in many cases, so as to completely do away with the conditions under which phthisis was acquired. Years will probably elapse before the disease can be regarded as cured, or even permanently arrested.

The treatment of the hæmoptysis which occurs in disease of the heart does not call for extended consideration. This form of hæmorrhage is the result of thrombosis or embolism of a branch of the pulmonary artery. It is most common in mitral disease, but may occur whenever from any cause the blood current in the pulmonary artery is feeble or the circulation in its branches is impeded. The pulmonary arterioles are non-anastomosing terminal arteries, and if one of them is obstructed by a thrombus or an embolus, the tissues of the affected region are deprived of their blood supply and undergo degenerative changes. In the absence of pressure from the side of the pulmonary artery, a reflux flow of blood from the veins takes place and the capillaries are again gradually filled with blood. According to Litten, the refilling of the capillaries is at least partly due to an inflow of blood from neighboring unobstructed arterioles. The blood from the adjacent vessels is, however, under very low pressure, which is not sufficient to establish a current through the obstructed area into the veins. The blood therefore stagnates, the capillaries become overfilled, their walls suffer in their nutrition, and permit the escape of blood into the surrounding tissues. A hæmorrhagic infarct is thus formed and hæmoptysis readily occurs. Owing to the low blood pressure, the effused blood tends to clot and the hæmorrhage usually ceases if the patient remains at rest. After a proper period of rest in bed, the indication is to strengthen the action of the heart to prevent thrombosis in other vessels with a recurrence of the hæmorrhage. Strychnine, digitalis, and other cardiac tonics should be prescribed, and all measures taken to improve the nutrition of the patient. The general treatment, in fact, should be sustaining, as in the case of the early hæmoptysis of tuberculosis.

**The Woman's Medical College, of Baltimore.**—We learn that Dr. Edward N. Brush, superintendent of the Sheppard Asylum, has been elected professor of psychiatry in the college.

## PRIMARY ERYSIPELAS OF THE PHARYNX.\*

By WILLIAM PORTER, A. M., M. D.,

ST. LOUIS.

ERYSIPELAS of the upper air-passages is rare—at least our recognition of it is rare—yet I can not but believe that more frequently than we know a true case, involving only the mucous membrane, may run its course without recognition.

My own experience with this type of disease in the respiratory tract is not great, and I find, in looking up the general and special literature, that the reported cases are exceedingly few. Only those cases have been cited in which there was an external inflammation some time during the course of the disease, and upon which the diagnosis was founded. Indeed, it is difficult to affirm a case to be erysipelas without cutaneous involvement, and for this reason the number of cases recognized is limited.

Again, the treatment often employed in many cases of acute pharyngitis and laryngitis is well adapted to erysipelatous disease, and it is possible that true cases are cut short, or successfully conducted as simple inflammations.

In a paper read before the association in 1880 (*Archives of Laryngology*, vol. i, No. 4) I reported two cases of primary erysipelas of the larynx. As this was before our proceedings were preserved in their present admirable form, I venture to briefly refer to these instances, and will add the history of a case of naso-pharyngeal erysipelas occurring within the last few weeks.

CASE I.—The earliest recorded case of which I have knowledge of erysipelas of the air-passages without cutaneous disease is one that came under my care years ago at the London Hospital. As the notes of this case were published in full by Mackenzie, in his work upon *Diseases of the Larynx, Pharynx, and Trachea*, they need not be repeated in detail. The main points in the case were:

A man, aged thirty-five years, laborer, was admitted to accident ward on account of fracture of the right internal malleolus. There was nothing unusual about the case for ten days; then there was some pain in the throat, with hoarseness and a little fever, which increased until, on the second day the temperature was 102°, hoarseness was marked, and there was some dyspnea.

The third morning he was transferred to a ward in my service and I saw him almost hourly. There was acute inflammation of the larynx with marked swelling of the ventricular bands. Dr. Mackenzie saw him on the third day. The inflammation had advanced upward, the epiglottis being now involved; it was infiltrated and eroded. There was also evidence of bronchial and pneumonic inflammation, but the dyspnea was so great that the changed respiratory sounds could not be well defined.

At midnight of the fourth day I opened the larynx. The patient lived forty-six hours after the operation, during which time a distinct friction sound made its appearance at the cardiac apex, and an erysipelatous flush

surrounded the tracheal wound. The notes of this case contain the first and, so far as I have knowledge, the only full record of an autopsy in primary erysipelas of the larynx. Without quoting them, I beg to refer to their publication as before cited.

The second instance occurred a few years later in a patient of Dr. Miller and Dr. Bond, of St. Louis, who asked me to see the patient, a merchant, aged twenty-six years, who had been exposed to erysipelas a week previous. The general appearance and symptoms were similar to those in the first case. Tracheotomy was done, the only result being to seemingly prolong life a few hours and render the condition of the patient easier. There was no autopsy.

In the third case, which has been but recently under my care, the larynx escaped, but the erysipelatous inflammation of the pharynx and nasopharynx was well marked. The patient, a prominent young business man of good habits and without knowledge of exposure, consulted me about four weeks ago, complaining of pain in the frontal region, fever, and great thirst. I found the turbinated region acutely inflamed, temperature 103°, pulse 130, tongue furred, and patient very nervous. He had, during the previous week, had pain in the back and in the larger muscles, and, at times, chill alternating with fever.

The next morning the pharynx was involved, and there was a well-marked characteristic flush over the external surface of the nose, extending well down to the cheek. The temperature was 104.5°, and the disease made rapid progress. The right Eustachian tube became involved, and, finally, the corresponding middle ear. Under a vigorous treatment with iron, and at times pilocarpine, with free insufflations of stearate of zinc and applications of ergot externally, the symptoms yielded, although there was the usual tendency to relapse. At this writing, May 1st, the patient is entirely well, except for a gradually diminishing otorrhœa.

These three cases in my own experience, as well as some others less well defined, have convinced me that some instances of acute laryngitis or pharyngitis are of erysipelatous origin. Clinically and bacteriologically the conclusion is a reasonable one. When the external evidence follows, the diagnosis is easy, but fortunately for the patient, though unfortunately for the classification, this is not always the case.

My thought in closing is, that where we have general symptoms, such as are common in erysipelas, with acute inflammation of the mucous membrane of the air-passages, with swelling and some edema, especially if the margin is well defined, we should suspect erysipelas, even if there is no cutaneous involvement.

[Since this was written my attention has been called to an interesting case of erysipelas beginning in the pharynx, and extending along the Eustachian tube, involving the right mastoid process. The report of this case, by Dr. L. T. Riesmeyer, is in the *Medical Review* for May, 1890.]

Board Examinations in Massachusetts.—“The recent examination of candidates for license to practise medicine in the State of Massachusetts resulted in the rejection of twenty-five out of one hundred and ninety-eight applicants. Sixteen out of the number rejected were not graduates in medicine.”—*American Medico-Surgical Bulletin*.

## SEROPURULENT MAXILLARY SINUSITIS IN CHRONIC LEAD-POISONING.\*

By HENRY LEWIS WAGNER, M.D., PH.D.,

PROFESSOR OF RHINO-LARYNGOLOGY, SAN FRANCISCO POLYTECHNIC

(UNIVERSITY OF CALIFORNIA);

FELLOW OF THE AMERICAN LARYNGOLOGICAL ASSOCIATION;

HONORARY CORRESPONDENT

DE LA SOCIÉTÉ FRANÇAISE D'OTOLOGIE, DE LARYNGOLOGIE ET DE RHINOLOGIE.

THE advancement made in the study of aetiology in diseases of the nasal sinuses has greatly improved the methods of treatment. The results in this study are obtained not only by histological and bacteriological analyses, including post-mortem examinations, but also depend upon a careful examination of the whole system.

The following case fully illustrates the views on this subject:

H. M. (aged thirty-two years; occupation, carriage painter for twelve years; parents healthy) consulted me a year ago for severe neuralgia of the right supra-orbital region. These neuralgic pains had existed for three consecutive years, occurring daily at intervals of from one to twelve hours, and consequently the patient was obliged to relinquish all work. He was afflicted with hyperosmia, strong odors of any kind producing pain. Opium and various coal-tar derivatives were prescribed by his former physicians without any result, and the resection of the right supra-orbital nerve even failed to bring relief. All teeth in the upper jaw—some of them decayed and discolored—had been extracted, the source of trouble being located there, but no relief followed.

EXAMINATION.—Patient a well-built man, skin yellow in color, flesh lacking in firmness, no syphilis, eyes and ears normal, throat showed slight pharyngitis sicca. Nose: Left side normal; right, slight hypertrophy of the middle and lower turbinated bodies. At the entrance of the hiatus semilunaris a crust formed daily, which could easily be removed, and a slight seropurulent discharge, containing *Staphylococcus aureus* and a few non-pathogenic cocci, could only be observed every second

Normal antrum of H. M.

or third day. Face: Transillumination showed little difference between the two sides. No external swelling of face. Pressure on the supra-orbital region produced no pain. Mouth: Hypertrophy of the right upper gum; no blue lead line could be detected. Pressing upon the region of the right first molar produced severe neuralgic pain. This assured me that the cause of the trouble existed in the right antrum. Being unable to probe or irrigate the antrum through the hiatus semilunaris, I

entered the cavity through the hard palate under cocaine anæsthesia with the aid of a spearhead drill—this method, which is quick and painless, I employ frequently—and by injecting sterilized warm water a slight seropurulent discharge was observed coming from the right nostril. Shortly after the patient was somewhat relieved, and I decided to open the antrum through the canine fossa. This was accomplished under chloroform with a large trephine drill. The antrum showed in the lower and side walls a peculiar bluish-gray hypertrophy of the mucous membrane. Probing did not reveal any caries of bone, but touching certain places produced severe pain. Microscopical examination of the hypertrophy, made by

Seropurulent maxillary sinus in chronic lead poisoning.

Dr. D. Montgomery, showed "loose connective tissue infiltrated with much serum and a fair number of round cells of inflammation; the piece of tissue had a covering of columnar epithelium. There were some micrococci in the tissue." After thorough removal of the hypertrophied tissue, dry treatment with borated gauze gave no relief, and also other methods of treatment were unsuccessful. I then decided to examine the urine for albumin, sugar, and lead, none of which were found; but, on examining fresh tissue, removed from the antrum, I found with sulphide of sodium the characteristic lead reaction. I placed the patient at once under iodide treatment, and in a few days he was relieved of all pain; the seropurulent discharge then ceased, and with it the formation of crusts.

Traces of lead were now detected in the urine. The patient has steadily improved, and has remained ever since free from pain.

In this case we must assign the diseased condition of the antrum, including the neuritis of various nerves, to the deposit of lead, perhaps as an albuminate. Similar conditions have been observed in a few eye cases (Stood), where optic neuritis, accompanied by severe headaches, was produced by chronic lead-poisoning.

NO. 506 SUTTER STREET.

## NASAL SARCOMA CURED BY OPERATION.

By G. MELVILLE BLACK, M.D.,

DENVER.

PROFESSOR OF LARYNGOLOGY AND RHINOLOGY  
IN THE MEDICAL DEPARTMENT OF THE UNIVERSITY OF COLORADO.

OWING to the rarity of this affection, and the still greater infrequency with which we find our efforts rewarded with success, I feel that it will be of interest that the case be reported in full.

On the 7th of April, 1894, Dr. McLauthlin, of this city, asked me to examine the nose of a patient of his

\* Read before the American Laryngological Association at its eighteenth annual congress.

who had been having some elevation of temperature that he was unable to account for.

I found Miss L., aged thirty-eight years, to be very weak and unable to sit up, and suffering from extreme frontal headache, with temperature of 101° F. She informed me that her fever had begun about ten days prior to my visit, and that at the same time the right side of her nose began to stop up, which resulted in complete occlusion in forty-eight hours. She was not aware of having had any nasal trouble before, although she had noticed for some time that the right side of her nose was not so free as the left, and that she had occasional nasal hæmorrhages, but could not say from which side they came.

The nose externally was slightly reddened, and very markedly enlarged on the right side, with extension of the redness and swelling to a less extent under the right eye. Pressure over any part of this area was painful. Protruding from the right anterior nares was a red and rather hard lobulated tumor, which bled upon slight manipulation. Inspection of the left nasal chamber showed the septum to be deviated toward the left so as to be in contact with the turbinated bodies. My advice was that the growth should be removed at once. It was impossible to say if the presence of this growth was alone responsible for her temperature and general physical condition. There was no question in my mind that its removal would be productive of benefit. A specific history could be eliminated beyond any question. Miss L. was removed to St. Luke's Hospital, where a more complete examination was made. Upon inspection of the post-nasal space it was found to be free, but the tumor could be plainly seen protruding from the right posterior nares. A view of the interior of the right side of the nose could not be obtained, owing to the growth filling that chamber so completely.

On April 8th she was etherized, and the cold snare used to remove as much of the tumor as it would engage. I first packed the right posterior nares to prevent the blood from running down into the air-passages. After removal of the growth, I found no trouble in passing my little finger into the nasal chamber and exploring the region of the middle turbinated body. I found this region still occupied by a very large mass of tumor. Hemorrhage was very moderate, so I introduced a strong sharp curette and thoroughly scraped this region. Hemorrhage was becoming pretty free, so I deemed it best not to attempt the removal of anything more. I then packed the entire right chamber with strips of iodoform gauze. This practically stopped the bleeding with the exception of a little oozing.

**APPEARANCES OF THE TUMOR.**—It was an inch and a half long, three quarters of an inch wide, by an inch high. Its general appearance was a dark red, mottled in places, with a rough surface, and quite firm to the touch. On its outer side there was a ragged hole about two millimetres deep by four millimetres in diameter, evidently a point of beginning ulceration.

**PROGRESS OF THE CASE.**—The nasal packings were removed at the end of twenty-four hours and replaced by a less amount, as the hæmorrhage was insignificant. From this time on she gradually gained in strength, so that at the end of a week she was able to pay me daily visits at my office. The temperature has been normal since the second day after the operation.

April 16th.—Removed another piece of tumor to-day, under cocaine anæsthesia, with the cold snare, from the posterior part of the middle turbinated body. Size of

piece removed, an inch long by half an inch wide in both its other diameters. It had the same general appearance as the first piece removed.

18th.—After cleansing the part, I removed a number of remnants of the growth with the cold snare and curette, under cocaine anæsthesia.

19th.—After thorough cleansing, I found what looked to be granulation tissue covering the middle turbinated body, and completely filling the middle meatus. This tissue I thoroughly cauterized with trichloroacetic acid.

May 1st.—The eschar from the cauterization came away to-day, leaving a perfectly clean middle turbinated body, with not a vestige of the growth to be seen anywhere. The nose looks normal externally, and the patient is free from all pain.

7th.—The part is still clean. No signs of recurrence. Considerable secretion accumulates and tends to form scabs in the middle turbinated region, unless it is cleansed several times a day.

12th.—Less secretion. Otherwise no change.

15th.—Her home is in New Jersey; she has only been here on a visit. She leaves to-night, not to return. She takes a letter to Dr. Charles H. Knight, of New York, and will consult him as soon as she arrives there on her way home. She carries with her two microscopic slides of the growth. The nature of it having been pronounced malignant, I explained to her that it would in all probability return, and that she must see Dr. Knight regularly, so that steps might be taken to do a more extensive operation if necessary. I was somewhat fearful that the maxillary sinus was involved, as a slight difference was noticeable on transillumination.

I have not seen Miss L. since she went home, but have heard from her, as well as from Dr. Knight, quite often. The reports have been that she has had no further trouble from any recurrence of the growth. Dr. Knight also wrote me that he had examined the slides sent him, and that there seemed to be no doubt, so far as the microscope went, that the growth was sarcomatous.

The following is a part of a letter received from Dr. Knight a few weeks ago, in response to a letter of mine inquiring after Miss L. preparatory to writing this report. He says: "As a matter of fact there is not much to say. You evidently made a clean, thorough job of it, since there has not been, up to the present time, the slightest evidence of recurrence. The patient has gained in weight, and improved very much in her general condition. She has severe headaches at long intervals, but no pain referred especially to the affected nostril. Since contracting a violent cold last fall she has had more or less catarrhal secretion. The accessory sinuses do not seem to be implicated, and the local condition may be considered satisfactory." Dr. Knight had examined Miss L. just a few days before he wrote this.

The report from the pathologist will complete the history of this case. The clinical appearance, together with the macroscopical and microscopical appearance of the growth, certainly warranted me in believing that I had to contend with a genuine sarcoma. Over two years have now elapsed, and there has been no recurrence of the growth. I have therefore felt that the ease with

which it was cured was due to a mistaken diagnosis. I shall leave you to judge if this should be recorded as a case of cured nasal sarcoma.

Warren, in his *Surgical Pathology*, says: "Sarcoma of the nasal passage is not a very rare disease. The round-cell and alveolar forms of sarcoma seem to be the prevailing types of growth. Fibrosarcoma and myxosarcoma are seen, and also angiosarcoma and melanosarcoma. The disease occurs as a pediculated tumor attached, with about equal frequency, to the outer and inner walls of the nasal cavity. The average age at which the disease appears is about forty years, and it is seen about equally in males and females. The disease does not appear to show the same malignant tendencies in the nasal passage that it does in other localities. Many of the reported cases were well, without recurrence, several months after the operation."

The following report is from the pathologist, Dr. H. C. Crouch, of the Medical Department of the University of Colorado:

Two sections stained with logwood and mounted in Canada balsam were submitted for examination. The external surface consisted of a single uninterrupted layer of delicate columnar epithelium. The bulk of the sections consisted of rather large, round, and oval cells, with a distinct nucleus and cell protoplasm. The stroma varied in the different parts, being more abundant with fewer cells in certain portions, and less marked in others. In parts the stroma showed a marked alveolar arrangement, including nests of the above-described cells. In other parts the alveolar arrangement of the stroma and cells was evident. In certain portions of the section where the cells had fallen out during the manipulation, a fine reticulum was visible, and in the alveoli described it was often possible to trace the fine fibrillæ penetrating between the cells. In accord with the foregoing appearances, a diagnosis was made of alveolar sarcoma.

In closing, I desire to thank Dr. Charles H. Knight for the reports he has made to me of the progress of the case. I desire to thank Dr. H. C. Crouch for his very accurate report of the microscopic appearance of the growth.

SEEDE BOOK.

## HYDROZONE IN GASTRIC AND INTESTINAL DISORDERS.

By JOHN AULDE, M. D.,  
PHILADELPHIA.

A PERIOD of nearly twelve years has elapsed since I first began the clinical use of hydrogen dioxide, generally referred to at that time as the peroxide of hydrogen. In 1887 I published a paper giving a detailed account of several cases in which it had been employed by inhalation, but even then I was thirty years behind the report of Dr. (now Sir) Benjamin Ward Richardson, of London, who had made a thorough investigation of its antiseptic, detergent, and healing properties. Notwithstanding the fact that this preparation had been known

to the medical profession for that length of time it had achieved little or no reputation. This, however, may be explained by the fact that the discovery preceded the dawn of bacteriology. Indeed, I was one of the early contributors to medical literature relating to the clinical value of this product, and since that time I have published a number of articles, embracing practically every application, both medical and surgical, to which hydrogen dioxide is adapted.

In the present communication it is my object to direct the attention of the profession to its special value in the treatment of gastric and intestinal disorders. In gastritis, for example, there is no antiseptic which can be given with so much benefit as this remedy, because its effect is immediate, and even in considerable doses it is absolutely harmless. The same is true in regard to its employment in typhoid fever, cholera infantum, and Asiatic cholera. In the latter disease its efficacy has been thoroughly demonstrated by a number of well-known physicians, and its applicability in cholera infantum is well known to those physicians who have given careful attention to the most modern methods in the treatment of this class of cases.

The following brief notes will be sufficient to indicate the availability of this remedy in the treatment of the disorders already mentioned, although, in view of the fact that hydrozone is a more concentrated product, and withal a permanent solution, this latter remedy should have the preference. It contains at least double the volume of nascent oxygen which has heretofore been the standard for the medicinal peroxide of hydrogen.

In gastritis, either acute, subacute, or chronic, we have to deal with an unhealthy condition of the lining membrane of the stomach. The inflammation is attended with an increased output of mucus, which seriously interferes with the normal functions of the peptic glands. By the introduction of a small quantity of hydrozone, in the strength of one part to thirty-two parts of boiled or sterilized water, this objectionable mucus is at once destroyed by the action of the oxygen which is released, and the contents of the stomach remaining are promptly discharged into the small intestine. A patient suffering from gastritis should take at least half an hour before meals from two to four ounces of diluted hydrozone (one to thirty-two) and lie on the right side so as to facilitate the action of the stomach in discharging its contents.\* The antiseptic properties of hydrozone thus used are sufficient to destroy the micro-organisms and leave the stomach in a healthy condition for the absorption of nutritive pabulum. All forms of fermentation are promptly subdued by the active oxidation resulting from the liberation of nascent oxygen. The patient is then in a condi-

\* In chronic cases with a large output of gastric mucus, and particularly in gastric ulcer, concentrated solutions are not well borne at first, owing to the formation of gas, but this difficulty disappears with the continued use of the remedy, and no treatment of gastric ulcer can be regarded as complete without the local employment of hydrogen dioxide or hydrozone.

tion to take suitable food, which should be nutritious and easily digested, liquids being preferred until the active symptoms have subsided. Later, small portions of solid food can be ingested, but all food stuffs of a starchy character must be thoroughly masticated, in order to secure the action of the salivary secretion upon the starch granules, breaking them up, and lessening the tendency to fermentation in the stomach. After taking a meal, a patient with gastritis should follow it with medicinal doses of glycozone, which contains, in addition to the nascent oxygen contained in hydrozone, a percentage of glycerin which favors osmosis and assists in re-establishing the functional activity of both the peptic and mucous glands of the organ.

In the treatment of cholera infantum, typhoid fever, and Asiatic cholera, the same general plan should be adopted in dealing with the stomach, always bearing in mind the necessity for having the patient remain in the recumbent position and on the right side for at least half an hour after the ingestion of the solution. In addition, however, to the preliminary treatment of the stomach, the same solution (one to thirty-two) is used as an injection into the lower bowel, care being exercised to insure its introduction as high up as possible. This can be managed by having the patient lie on the left side, with the hips well elevated, and the employment of a long, flexible rectal tube. In this manner we secure and maintain an antiseptic condition in both the stomach and large intestine, the importance of which will be understood when we consider the large number of micro-organisms which grow under these favorable conditions with such remarkable rapidity.

When deemed advisable, the solution introduced into the lower bowel may be combined with large quantities of either hot or cold water, which enables us to obtain the benefits of irrigation in addition to the antiseptic effects. These irrigations may be employed as frequently as deemed advisable by the medical attendant, but they will usually prove satisfactory if administered at intervals of four hours.

Although brief, it is believed this communication will prove serviceable to a large number of practitioners who have hitherto found serious difficulties in counteracting the mephitic influences of bacteria in this class of disorders, and the clinical virtues of the remedy being now so fully recognized, no one will hesitate to adopt the methods suggested, which may be conveniently carried out in addition to the usual routine treatment.

**The Marion Sims College of Medicine, of St. Louis.**—The following minute, prepared by a committee consisting of Dr. B. H. Hypes, Dr. R. C. Atkinson, and Dr. C. Parck, has been authorized by the faculty:

"Whereas, Dr. I. N. Love has found it incumbent on him to sever his connection with the Marion Sims College of Medicine, the members of the faculty of that institution embrace this occasion to express their appreciation of his past services and their hope that in all his future connections he will find both pleasure and profit."

## A CASE OF GONORRHEA COMPLICATED WITH DOUBLE EPIDIDYMITIS IN A BOY TWELVE YEARS OF AGE.

By E. S. COX, M.D.,  
GALVESTON, TEXAS.

It is very seldom indeed that his "Satanic Majesty" encounters one so young "prowling" about the premises of the "demimonde," and receiving admittance into the realms of that unholy sanctum, as was the case in the instance about to be recorded, and it is a sad commentary on those who follow prostitution as a profession (or means of livelihood) that one so young should be admitted into such a house. But worse than that—than all—that he should be the unlucky and unfortunate victim of a gonorrheal virus, with double epididymitis as a complication, which not only occasioned great suffering, but brought sorrow and mortification to his honorable parents.

L. M., the subject of this paper, twelve years of age, of medium size for one of his age (excepting the "offending member"), not especially precocious, closely watched by his scrupulously religious parents, and not allowed to associate with other boys, lest something damaging to his moral or spiritual welfare might result, consulted his grandmother about a "dreadful burning" in his penis when he made water, and she, thinking it a slight trouble, gave him some flaxseed tea and a few pills to move his bowels. The boy not improving under her treatment, I was called in, and found him in the following condition: His penis was inflamed and swollen; temperature, 102° F.; enlarged lymphatics; excruciating pain in the inguinal region; testicles immensely swollen; dysuria; bowels constipated. Owing to the epididymitis, there was almost complete cessation of the gonorrheal discharge, which subsequently recurred after the subsidence of the acute inflammation of the testicles.

He gave a connected history, after being assured that I would not divulge the secret, which clearly established the ætiology. The usual remedies which are indicated in such cases were prescribed. There is nothing in the case to attract attention but the tender age of the subject.

## A CASE OF BRAIN ABSCESS SECONDARY TO CHRONIC SUPPURATIVE OTITIS MEDIA. AND PRESENTING UNUSUAL SYMPTOMS. OPERATION. RECOVERY.\*

By GORHAM BACON, M.D.

E., a college graduate, thirty-two years of age, of strong constitution, was referred to me in December, 1895, by Dr. W. A. Bartlett, of this city.

The history of the case is that the patient had a chronic suppurative otitis media (left side) of at least fifteen years' duration, as a result of measles, and that during this time he has practically received no treatment for it. For some time past his friends have noticed that he has at times acted strangely and has complained occasionally of some pain in his head, but not sufficient

\* Read before the American Otological Society at its twenty-ninth annual meeting.

to keep him away from his business, which is that of editing an insurance journal. Four days ago he had very severe pain in the left ear and the discharge was very profuse. On December 5th he was visited at his home by Dr. Bartlett, who found that he had a temperature of 104° F., an intense headache, and marked pain in the ear. In the afternoon he had a general convulsion lasting twenty minutes, with violent muscular twitchings and frothing at the mouth. He was unconscious during the convulsion and for half an hour afterward. I had him removed at once to a private room in the New York Eye and Ear Infirmary, where I saw him that same evening, December 5th, at 9 P. M. At that time the temperature was 100° F., pulse 104, and respirations 26. He was perfectly conscious, but complained of severe headache. The auditory canal contained foul-smelling pus and granulations.

**OPERATION.**—The patient was etherized. Assisted by my colleague Dr. J. L. Adams, I made a long incision over the mastoid process down to the bone and close to the auricle. The bone was found very dense and the mastoid antrum was reached with much difficulty by means of chisels and gouges. The lateral sinus was slightly injured in chiseling, on account of its being out of its usual position, from which there was a copious flow of blood, so that it became necessary to plug the sinus with iodoform gauze. The external meatus was thoroughly curetted; the wound was washed with a bichloride solution and packed with gauze after the upper angle had been brought together with sutures. The patient rallied well from the operation.

**December 6th.**—Temperature normal this morning. He complains of thirst. He has complete facial paralysis of the left side, the nerve undoubtedly having been injured in the chiseling of the bone.

**7th.**—The fundus of each eye was examined by Dr. Gruening to-day and found normal. The patient is very comfortable and slept well, and the headache is much less. 6 A. M., temperature, 101° F.; 12 noon, 99°; 9 P. M., 101°.

**8th.**—Patient restless and confused, apparently aphasic, unable to ask for what he wants. He was seen to-day by Dr. M. Allen Starr. 3 A. M., temperature, 102.4° F.; 6 A. M., 100°; 1 P. M., 99°; 9 P. M., 102.2°.

**9th.**—The patient had a severe chill during the night lasting fifteen minutes, followed by profuse perspiration, with severe headache. He is markedly aphasic. The aphasia is chiefly of conduction, resulting in verbal amnesia. Urine contains a trace of albumin and one per cent. of sugar. 3 A. M., temperature, 104° F.; 9 A. M., 101.9; 12 noon, 101°; 6 P. M., 104°; 104.8° in the evening. Wound dressed.

**10th.**—Temperature lower. Patient less confused and more comfortable. Fundus of each eye normal. He was again seen by Dr. Starr and Dr. Gruening, and it was deemed advisable to explore thoroughly the lateral sinus, and if nothing was found there, to remove a button of bone over the temporo-sphenoidal lobe. 3 A. M., temperature, 101.9° F.; 11 A. M., 100.2°; 12 midnight, 102°.

**SECOND OPERATION.**—After ether was administered, assisted by Dr. Gruening and Dr. Adams, I again exposed the sinus, which was pulsating, and inserted a hypodermic needle in different directions, always withdrawing blood. The original incision over the mastoid was then carried an inch and a half upward and a horizontal incision was made forward for the same distance. A button of bone was removed with a trephine three quarters of an inch in diameter, the centre pin of the trephine

being placed at a point two inches above the centre of the external meatus. The dura was exposed and was found slightly bulging and pulsating. The opening in the skull was enlarged with the rongeur forceps in a direction downward and backward. In separating the thickened dura from the tympanic roof, to which it was adherent, pus was seen to exude. There was found, with a probe, an opening at this point in the dura, and half an ounce of pus escaped. A Y-shaped incision was made in the dura and I introduced my little finger (its whole length) in a direction inward, upward, and backward, and found a good-sized abscess cavity, but without any sac. More pus and broken-down brain tissue, of a very offensive odor, came away. Altogether there was at least an ounce and a half of pus. I then chiseled away the bridge of bone between the opening made with the trephine and the antrum, in order to secure as perfect drainage as possible. The external wound was irrigated with boric-acid solution, but the abscess cavity was not washed out. The latter was then loosely packed with iodoform gauze as well as the external wound and the whole bandaged. 3 A. M., temperature, 97.6° F.; 6 A. M., 102.6°; 9 A. M., 99°; 1 P. M., 98.4°.

**12th.**—The patient was restless during the night. Still confused and aphasic. The external dressings were removed, as they were blood-stained, and new ones re-applied. He takes his nourishment well. 3 A. M., temperature, 100° F.; 9 A. M., 99.8°; 9 P. M., 101°.

**13th.**—The packing was removed from the abscess cavity to-day for the first time, as there was more or less elevation of temperature during the early morning from 3 to 6 A. M. The pus was most offensive. I repacked the abscess cavity with iodoform gauze. He complained of severe pain afterward and was very drowsy, and on waking after deep sleep was very confused. At 7 P. M. he had a tonic convulsion, lasting a few minutes, followed by marked headache, at which time he did not seem to recognize any one. 3 A. M., temperature, 103° F.; 9 A. M., 98.4°; 9 P. M., 99°; 12 midnight, 101.4°.

**14th.**—Since yesterday he has had three severe convulsions and two lighter ones. At the dressing of the wound, about five drachms of thin pus escaped, and the patient had a slight convulsion during the dressing with unconsciousness for at least two minutes. 3 A. M., temperature, 97.2° F.; 9 A. M., 99°; 6 P. M., 98.2°; 12 midnight, 100°.

**15th.**—Much brighter; he recognizes his friends. Abscess cavity smaller. I have introduced my little finger each day to be sure that the wound was filling up from the bottom. His general condition has much improved. 3 A. M., temperature, 97.8° F.; 9 A. M., 98°; 6 P. M., 98.4°.

**17th.**—Steady improvement. The wound is dressed daily and the pus has much less odor. He is still unable to name simple objects.

**19th.**—At times he is very much confused and restless, then again he talks rationally and recognizes every one. Wound granulating.

**22d.**—He read a newspaper to-day, but evidently does not understand very much. No word deafness and no motor aphasia, but he can not remember names, and especially proper names.

**30th.**—His condition has steadily improved. Patient entirely rational. The wound is dressed daily.

**January 3, 1896.**—Aphasia disappearing. The constant current is applied to the face daily.

**29th.**—During this month there has been a constant but steady improvement in all symptoms and the aphasia has practically disappeared. He has gained very much

in weight. The external wound has almost entirely healed, and the patient was allowed to leave the hospital to-day.

*June 1st.*—The patient has been under treatment ever since. There still remains a very small sinus over the antrum and leading down to it. A small sequestrum of bone came away from the mastoid region some little time ago. There is still more or less discharge of pus from the external meatus. The patient feels well and is able to ride a bicycle, and has attended to business for the past three months. The facial paralysis is disappearing.

Of five patients with brain abscess whom I have had under observation and who were operated upon, two have recovered and three have died. Of these cases, three were abscesses of the temporo-sphenoidal lobe, one was an extradural abscess,\* and one was an abscess in the cerebellum.† The other case that recovered besides the one just reported was the patient with the extradural abscess.

All these cases of temporo-sphenoidal abscess occurred on the left side of the brain, and all three patients well-marked aphasic symptoms. All had severe headache. In two the pulse was slow and full and the temperature almost normal or subnormal, while in the one reported above the temperature was high and the pulse rapid, and every indication seemed to point to a thrombus of the lateral sinus. I was firmly convinced, however, before the second operation that the case was one of temporo-sphenoidal abscess rather than of thrombosis, as I had injured the lateral sinus when opening the mastoid antrum and had had a copious flow of blood from it.

When suppurative otitis media on the left side occurs in a patient who is right-handed, followed by a cerebral complication, I believe that aphasic symptoms are of the greatest value in arriving at a diagnosis of abscess in the temporo-sphenoidal lobe. A slow pulse is also extremely characteristic.

This case illustrates the point that a patient with a cerebral abscess may have chills, high temperature, rapid pulse, and convulsions, so that it becomes extremely difficult in such to make a differential diagnosis between abscess of the brain and thrombosis of the lateral sinus.

(Of the two other cases of temporo-sphenoidal abscess referred to in this paper, one was published in the *Transactions of the American Otological Society*, 1888, and a report of the other one will appear in the August number of the *Archives of Otolaryngology*, 1896.)

## A CASE OF PRECOCIOUS MENSTRUATION.‡

By J. W. IRION, M.D.,

PROFESSOR OF HYGIENE AND STATE MEDICINE,  
MEDICAL DEPARTMENT, FORT WORTH UNIVERSITY.

I HAVE under my care such a remarkable case of precocious menstruation that I feel it my duty to report

it to the profession. In looking up the history of precocious menstruation I find but little concerning it, and no case so remarkable as the one I have under my observation.

On October 10, 1895, I was called to attend Mrs. N. in labor. She is of a German family, well formed, strong, and vigorous. This was her second labor, the first child having been a boy, a fine, vigorous child. At about 5 A. M. Mrs. N. was delivered of a girl infant weighing nine pounds and normal in physical condition. On the morning of the 17th I was called to see the baby. I found the infant in good condition, sleeping well, and taking its nourishment as it should. I was told by the mother that upon her usual examination of the child that morning she noted a bloody discharge from the vagina. Upon examination, I found the condition as the mother had described it. The child seemed in no way disturbed. The flow lasted for four days. In December the flow did not return and the child suffered with all the nervous phenomena that usually accompany the missing of a period in an adult, and she broke out from the top of her head to the soles of her feet with an eczema that persisted for some time, but gradually subsided. Her mother attributed the non-return of the flow in December to a rather cold bath the day before the flow was expected. Since December the flow has returned with perfect regularity, and the child is in good health, skin fair and clear, eyes bright and intelligent. The breasts and mons Veneris in the child are considerably developed, and during the flow the breasts enlarge and are somewhat sensitive to the touch. The mother's menstrual period was established at the age of thirteen years.

## Therapeutical Notes.

### Tincture of Aloes in the Treatment of Varicose Ulcers.

—According to Coffin (*Journal des maladies cutanées et syphilitiques*, 1896, No. 1; *Centralblatt für die gesamte Therapie*, August, 1896), small varicose ulcers of the feet may be treated advantageously with tincture of aloes. They are to be cleansed and disinfected and then smeared with the tincture. In the course of half an hour the tincture dries into a thin layer. Over it a dressing is applied consisting of a piece of gutta percha tissue, some wadding, and a bandage. At first the tincture causes some pain. The dressing is to be changed in four days.

### Paquelin's Cautey in the Treatment of Chancroid.

—Audry (*Monatshefte für praktische Dermatologie*, xxii, 10; *Centralblatt für die gesamte Therapie*, August, 1896) recommends the following treatment: Wash, cleanse, and dry the ulcer, and then hold the red-hot cautery close to it for an instant. One treatment converts the sore into a simple one which will heal quickly under iodoform.

### Camphor and Tannin in the Treatment of Erysipelas.

—The *Centralblatt für die gesamte Therapie* says that Rehbinder recommends painting the affected skin with this solution:

R	Tannic acid, }	of each.....	4 parts;
	Camphor, }		
	Spirit of ether.....	30	"

To be applied hourly for four or five times.

\* *New York Eye and Ear Infirmary Reports*, 1894.

† *American Journal of the Medical Sciences*, August, 1895.

‡ Reported to the North Texas Medical Association, June meeting, 1896, at McKinney, Texas.

**An Ointment for Fissure of the Anus.**—The *Centralblatt für die gesammte Therapie* credits the following formula to the *Revue de thérapeutique*:

R Extract of cicuta.....	5 parts:
Castor oil.....	15 "
Lanolin.....	30 "

M.

**A Dressing for Suppurating Wounds.**—Schwartz (*Journal des praticiens; Centralblatt für die gesammte Therapie*) recommends the following powder:

R Powdered iodoform,	
"    silol,	
Bismuth subnitrate,	equal parts,
Powdered charcoal,	
"    cinchona,	
"    benzoïn,	

**Valerianate of Creosote.**—According to E. Grawitz (*Therapeutische Monatshefte*, 1896, No. 7; *Therapeutische Wochenschrift*, July 19, 1896), this compound is neither caustic nor poisonous. It has the trade name of eosote. It comes in gelatin capsules, each containing about three grains. At first, a capsule is to be given three times a day, with an abundance of milk; afterward the number may be increased to two or three at a time. The compound is used for the same purposes as creosote.

**An Antiseptic Wash for the Mouth.**—The *Presse médicale* for July 18th contains the following formula:

R Thymol.....	4 grains;
Benzoic acid.....	45 "
Tincture of eucalyptus.....	225 "
Essence of peppermint.....	60 "
Chloroform.....	15 "
Alcohol.....	3 ounces.

M. Twenty drops of this solution, in a glass of water, may be used at a time.

**Tannigen in the Treatment of the Diarrhœa of Infants.**—Hock (*Wiener medizinische Blätter*, July 23, 1896) gives the following formula:

R Tannigen.....	30 grains;
Sugar of milk.....	45 "

M. Divide into ten powders. Half a powder (for a child a year old, a whole powder) may be given every four hours.

**Ichthylol in the Treatment of Pulmonary Tuberculosis.**—Scurpa (*Therapeutische Wochenschrift; Deutsche Medicinal-Zeitung*) employs the following formula:

R Ichthylol.....	1 part;
Water.....	3 "

M.

Twenty drops, in water, are to be taken in a day at first, and the daily amount gradually increased by ten drops at a time until it reaches two hundred drops.

**Sanoform, a New Substitute for Iodoform.**—Arnheim (*Allgemeine medicinische Centralzeitung*, 1896, No. 37; *Centralblatt für Chirurgie*, July 11, 1896) has used this proprietary preparation, known chemically as diiodosalicic-acid methylether, an odorless and tasteless powder, as a substitute for iodoform in seventy-two cases, in the form of powder, gauze, ointment, and collodion. It is readily soluble in alcohol, in ether, and in vaseline. His cases included forty-two of ulcers of the genitals, sixteen of phimosis, six of buboes, three of excision of ulcers, and five of pararitia. He thinks that sanoform is always as efficient as iodoform, and sometimes superior to it. No local irritation or any sign of poisoning with it has been observed by him. It costs no more than iodoform.

NEW YORK, SATURDAY, AUGUST 15, 1896.

### MARAGLIANO'S ANTITOXINE-SERUM TREATMENT OF PULMONARY CONSUMPTION.

IN the *Deutsche Medicinal-Zeitung* for July 27th there is an exceedingly satisfactory article on The Serum Treatment of Pulmonary Tuberculosis, by Dr. Zaeslein, of Genoa. The serum treatment, he remarks, consists essentially in introducing into the human body substances which either of themselves oppose the germ of the disease or lead to the formation of such material (antitoxines) in the organism. Koch's tuberculin, although it has proved a failure as a curative agent, does lead to a formation of antitoxine, but it is not known that sufficient antitoxine to prove curative can be produced by the use of safe doses. The employment of tuberculin as a therapeutic measure having therefore been practically renounced, some experimenters, especially Richet and Héricourt, sought to cure tuberculosis by injecting the normal serum of such animals as the goat and the dog, which are naturally almost completely proof against the disease; but the results were not very encouraging.

Then animals were treated with tuberculous matter, in order to engender large amounts of antitoxines in their blood. For that purpose Maragliano used cultures of the tubercle bacillus, but without living bacilli; Behring, Wernicke, Knorr, and Niemann employed tuberculin; Babes and Broca made use of the bacilli of the tuberculosis of birds, human tuberculin, and dead or attenuated cultures of the human bacillus; and Paquin used "cultures" from tuberculosis. The serum of animals systematically treated with any of these materials annuls the action of tuberculin; Maragliano first announced this with regard to his product, in August, 1895. Wernicke, Knorr, and Niemann employed only those culture products that resist heat, but Maragliano uses also those that are destroyed by heat, and Zaeslein thinks it probable that this is of great advantage. Babes and Paquin have had some good results, but there are no statistics to compare with Maragliano's, which now include four hundred and fifty cases. The use of his serum has passed the experimental stage

and may safely be received into practical therapeutics, for the dose in antitoxic units is adjustable and calculated for long periods and the use of the remedy rests on adequate clinical observation.

For the inoculation of animals, Maragliano uses the filtrate of cultures that have been heated, as well as that of those that have not been heated. The first-mentioned are prepared by steaming highly virulent pure cultures at a temperature of  $212^{\circ}$  F. for three or four days, and then treating them in the same way as for producing Koch's tuberculin; in the preparation of the last-mentioned, the cultures are filtered through a Chamberland filter at the ordinary temperature, and then placed in a vacuum with the temperature never above  $86^{\circ}$  F. The first product contains all the toxic elements that resist heat, i. e., the bacterial proteins, or tuberculins; in the second there are the toxalbumins, which do not bear heat, and tuberculins also, for in all cultures there are fragments of bacilli which doubtless contribute tuberculins to a solution. Now, as it is known that not all cultures are equally toxic, an unchanging toxic unit has to be established, in order that the animals may be inoculated uniformly. This is accomplished by greater or less concentration of the filtrates, and the unit consists of a weight sufficient to kill a healthy guinea-pig of a certain weight; in this case the two filtrates are concentrated to such a degree that a cubic centimetre will contain a hundred toxic units, i. e., a cubic centimetre for each fifteen hundred grains of the guinea-pig's weight will be required to kill the animal. In the inoculations, three parts of the heated and one part of the unheated filtrate are employed, the operator beginning with two milligrammes for each kilogramme of the animal's weight, and increasing the dose regularly by one milligramme daily until it reaches from forty to fifty milligrammes, at which it is to remain. Dogs, asses, and horses are employed, and ordinarily the inoculations are continued for six months. The animal will then withstand large doses of virulent cultures, even by intravenous injection. Before blood is drawn from the animal there is a pause of three or four weeks, in order to make sure that the serum contains no residue of the poisonous substances that have been injected. The serum is separated and treated according to the ordinary method.

The physiological action of the serum on man is as follows: In a healthy person, the curative serum as such has no effect on the temperature; however, like any other animal serum, even that of animals that have

not been inoculated, in certain individuals it may, especially if used in large doses, cause a rise of temperature, but the fact of its coming from an inoculated animal has nothing to do with this. It has no direct influence on the circulation; when, however, a tuberculous patient's general condition improves after a series of injections, the pulse grows correspondingly slower and fuller. There is often a striking increase in the number of leucocytes in the blood; in tuberculous persons the number of the red corpuscles and the amount of hæmoglobin also are increased in proportion to the improvement of the general condition. In general, there is no perceptible effect on the urine, but when a large dose, as much as ten cubic centimetres, is given at one time, temporary peptonuria may occur, but never glycosuria or albuminuria. The appetite is almost always increased, also the weight; if the loss of flesh has been only slight, there will be but little increase, but in very emaciated persons the gain will be striking, amounting in some instances to as much as thirty pounds.

Zaeslein then proceeds to the effects of the treatment on the manifestations of the disease, considering first those that are local. The chief effect elicited by auscultation, he says, is a diminution and final disappearance of the rales, which means a drying up of the deposits, beginning with those that are recent and slowly extending to the older ones. Subsequently the areas of dullness diminish or disappear. These effects occur even in cases in which no other measure has been of any avail and whether or not there is fever and whether or not heredity is playing a part. Now and then a tendency toward cure is perceptible within a few days, and usually in the course of a month, if the process is not too far advanced and not too many other bacilli are present. Slight fever usually disappears, slowly when the treatment is carried out according to Maragliano's directions; high fever may abate and, if the progress of the case is to be favorable, subside entirely. Very high fever and the subcontinuous fever which occurs in the final stage may be reduced or overcome if large doses of the serum are employed—from five to ten cubic centimetres every fifth, sixth, or seventh day, but only for two or three days; this effect is not constant and generally not lasting.

A tolerably constant effect is a gain in weight, even if the fever continues. Maragliano says: "The patient gains weight because he eats more, it is true, but it is because the serum treatment enables him to eat more." As the other symptoms are ameliorated, the number of

tubercle bacilli in the sputa becomes reduced, slowly of course in severe cases; finally they disappear entirely and not merely for the time being, provided the treatment is energetic and continued long enough. As regards the general condition, many patients say that they feel stronger after the first few injections, and they are inclined to do some work, which for a long time had been impossible for them; but this, of course, is only a subjective phenomenon. After further treatment the whole scene changes—there is a sharp appetite, the patients take long walks without exertion or fatigue, and they do not get out of breath. Moreover, their sleep is long and restful.

As regards the different forms and stages of the disease, Maragliano divides all cases of pulmonary tuberculosis into two great groups—those in which Koch's bacillus is the only micro-organism, or almost the only one, found in the sputa, and those in which there is an abundance of other microbes, such as streptococci, staphylococci, and the diplococcus of pneumonia, constituting what he calls "microbial associations." In these latter cases the cure, although not impossible, is difficult and protracted; they are the ones in which the old remedies must not be neglected on account of the serum treatment. Besides the question of which of these two great divisions the case belongs in, one has to take into account four other considerations: The "quality" of the disease (whether there is only catarrh or infiltration, whether the infiltration is compact or disseminated, whether there is a tendency to caseation or to cirrhosis, and whether or not there are cavities); its "quantity" (the amount of tissue diseased); its intensity; and the patient's general condition. All these data are of importance in the prognosis.

Maragliano's statistics relate to four hundred and forty-five [the article says four hundred and fifty] cases, including the eighty-two that he reported in August, 1895, before the Société française de médecine interne, those recorded or reported to him by other Italian physicians, and a few contributed from France and Austria. When Maragliano speaks of a cure, he means a "provisional cure," manifested by the disappearance of all subjective symptoms and all physical signs except dullness on percussion. The cases are divided into six groups as follows:

1. *Patients with destructive bronchopneumonia and cavities.* 105.

Cured .....	8
Improved .....	37

Not affected .....	37
Grew worse .....	23

Eighty-two of these patients had fever. It disappeared in twenty-nine, was reduced in sixteen, and remained stationary in thirty-seven. The local signs disappeared in twenty, were mitigated in thirty, and were unchanged in forty-eight. The weight increased in forty-three cases, remained stationary in twenty-six, and decreased in seven.

2. *Patients with destructive bronchopneumonia, without recognizable cavities, with "microbian associations,"* 85.

Cured .....	9
Improved .....	45
Not affected .....	24
Grew worse .....	7

The fever disappeared in forty, abated in eleven, and remained the same in twenty-one. The local signs disappeared in fifteen, were improved in forty, and remained unaffected in twenty-one. Forty-three gained flesh, four lost weight, and in twenty-two there was no change of weight.

3. *Patients with diffuse febrile pneumonia, with or without a destructive character,* 120.

Cured .....	11
Improved .....	61
Not affected .....	35
Grew worse .....	13

The fever disappeared in sixty, grew less in twenty-two, remained the same in twenty-nine, and increased in eight. The local signs vanished in twenty-four, were improved in fifty-one, remained stationary in twenty-nine, and were aggravated in twelve. Forty-eight gained flesh, eight lost, and in twenty-two there was no change.

4. *Patients with diffuse non-febrile bronchopneumonia, with or without destruction,* 47.

Cured .....	2
Improved .....	33
Not affected .....	11
Grew worse .....	1

The local signs disappeared in eleven, remained the same in thirteen, and were improved in twenty-two. The weight increased in twenty-four and was unchanged in twelve.

5. *Patients with circumscribed febrile bronchopneumonia.* 54.

Cured .....	20
Improved .....	31
Not affected .....	3

The fever disappeared in forty-seven, was unchanged in four, and was aggravated in one. The local signs disappeared in twenty-five, were improved in twenty-five, remained the same in three, and were intensified in one. Forty-four gained in weight and in four there was no change.

6. *Patients with circumscribed apyretic bronchopneumonia.* 34.

Cured ..... 22

Improved ..... 10

Not affected ..... 2

The local signs disappeared in twenty-three, were improved in eight, and were unchanged in two. The weight increased in twenty-seven and was not affected in one. It is explained that the omission of some of the data in the foregoing statistics was due to defective histories having been sent in some instances.

To summarize the results, the fever disappeared in 176 out of 322 cases—in 55 per cent. of cases of bronchopneumonia with "microbian associations," in 32 per cent. of those of cavities, in 48 per cent. of those of diffuse bronchopneumonia, and in 86 per cent. of those of circumscribed bronchopneumonia. The local signs disappeared in 27 per cent., were improved in 41 per cent., were unchanged in 30 per cent., and were aggravated in 6 per cent. [so the account says, but these numbers added together make 104; consequently there has been a slip of the pen]. There was an increase of weight in 57 per cent. The tubercle bacilli disappeared in 43.2 per cent. (in 54 per cent. of the febrile bronchopneumonias and in 88 per cent. of the non-febrile circumscribed bronchopneumonias).

As a general thing, a cubic centimetre of the serum was administered subcutaneously every other day, and the temperature was carefully observed. Inasmuch as a few persons are sensitive even to this dose, half a cubic centimetre may be given to begin with. Such individuals may be recognized by their showing a febrile reaction on the injection of two cubic centimetres of a physiological salt solution. In the great majority of instances there was neither a rise of temperature nor any other disturbance, even when the treatment was continued for many months. When a rise of temperature occurred the treatment was suspended until it fell, but even in such cases a definitive apyrexia occurred in time. When the treatment, thus employed, failed to affect patients who had high fever and were in bad general condition, from five to ten cubic centimetres of the serum were given every fifth day; when three

or four such injections had been given without avail, it was thought useless to continue with them, and the ordinary plan of using small doses was resumed.

The use of the serum should be continued until a cure results, then two injections a week should be given for two months, and after that one injection a week for a year. The side of the chest and the back are the preferable parts for the injections. They are no more painful than injections of morphine; occasionally a little swelling occurs, but it subsides in a few days, rarely there is urticaria, and no other accidents are observed. The serum is described as clear and free from flocculi and sediment. Not until it has been kept for a long time does it become turbid, and then it had better be discarded, although the flocculi seem to consist only of precipitated albumin.

#### THE USE OF DIPHTHERIA SERUM IN OZÆNA AND CHRONIC PURULENT OTITIS.

In the *Therapeutische Wochenschrift* for July 26th, Professor Gradenigo, of Turin, gives an outline of the researches made since Fränkel's, in 1882, into the ætiology of ozæna. He accepts the theory of its infective character and recognizes Belfanti's bacillus as its cause. On account of the close resemblance, in effects, between this bacillus and that of diphtheria, he has used the antidiphtheritic serum in thirty-two cases of ozæna. Sixteen of them were practically cured; that is, they were mitigated to the extent that the formation of crusts and the fœtor disappeared. In the other cases there was tangible improvement. Most of the patients had had the disease for a long time and had tried other treatment without avail. In the cases that were approximately cured, the duration of the treatment varied from thirty to sixty-eight days, and the number of units of serum employed in an individual case ranged from 5,200 to 27,200. In all the cases œdema at the site of the injection, urticaria, etc., followed after a certain number of injections had been used, but they were of brief continuance. In the sixteen cases that were cured, the duration of the treatment was from fifteen to seventy-two days, and the number of injections was from four to thirty-five, the number of units of serum used being from 5,200 to 48,000. Mild local or general reaction symptoms occurred in almost all these cases, and attacks of bleeding from the nose were observed.

Professor Gradenigo has employed the same treatment in two cases of chronic purulent otitis, or, rather, it happened that two of his ozæna patients were affected

with the ear disease also, and the serum treatment was observed to have a very favorable effect upon it. He considers Belfanti's discovery of the bacillus of ozæna not only of great practical benefit as leading to a successful treatment of the disease, but also of much importance in general pathology.

### MINOR PARAGRAPHS.

#### THE SERUM TREATMENT OF SYPHILIS.

PROFESSOR BOECK, of Christiania (*Archiv für Dermatologie und Syphilis*, xxv, 3; *Wiener medizinische Blätter*, July 30, 1896), resumed the serum treatment of syphilis in 1894, using the fluid removed from the tunica vaginalis in cases of hydrocele in syphilitic men. He comes to the following conclusions: 1. The symptoms of the primary period are more rapid in their involution than under the expectant treatment. 2. The secondary symptoms are somewhat delayed. 3. They are decidedly mitigated, so that the rash is hardly noticeable and the affections of the mucous membranes are strikingly slight. 4. The general condition is speedily improved. 5. The stage of secondary eruption is shortened. 6. The treatment is the more effective the earlier it is begun. 7. Serum from a person in the tertiary stage is more efficient than that from a person in the secondary stage. Although, on the whole, the serum treatment is not so effective as the use of mercury and iodine, it is deserving of further trial and may be regarded as a useful auxiliary.

#### THE NEXT MEETING OF THE BRITISH MEDICAL ASSOCIATION.

It is announced that the meeting of 1897 is to be held in Montreal. This news, we are confident, will prove quite as acceptable to the physicians of the United States as to those of the Dominion, and it can readily be foreseen that there will be a large attendance of Americans at the meeting.

### ITEMS.

**Infectious Diseases in New York.**—We are indebted to the Sanitary Bureau of the Health Department for the following statement of cases and deaths reported during the two weeks ending August 11, 1896:

DISEASES.	Week ending Aug. 4.		Week ending Aug. 11.	
	Cases.	Deaths.	Cases.	Deaths.
Typhoid fever.....	17	8	29	10
Scarlet fever.....	35	5	42	3
Cerebro-spinal meningitis.....	0	0	1	1
Measles.....	110	7	77	6
Diphtheria.....	146	18	138	36
Tuberculosis.....	183	103	177	84

**The New York City Health Department's Circular of Information regarding the Use of Mallein for the Diagnosis of Glandered Horses**, just issued, is as follows:

"The health department of New York city is prepared to furnish mallein for the diagnosis of glanders in horses. This is prepared by Nocard's method, and is furnished in vials containing a single dose of 2½ c. c. In order that accurate results may be obtained in all cases where mallein

is employed for the diagnosis of glanders, the following directions should be carefully followed:

1. The temperature of the animal to be tested should be taken three times a day for three days previous to the injection, to determine the mean temperature. 2. The animals to be tested should be protected against sun, rain, or wind, as these influences may occasionally cause a rise of temperature of one or two degrees or more, independent of the action of mallein. 3. On the day of injection, the temperature should be taken every two hours from early morning until late at night, and during the two succeeding days it should be taken three times a day. 4. The injection should be made into the shoulder, and the skin should be previously washed thoroughly with soap and water and then with some antiseptic solution, such as lysol 2 per cent., carbolic acid 5 per cent., or bichloride of mercury 1 to 1,000. Care should be taken to carefully sterilize the needle of the syringe after each injection, or, better, to use separate needles, if healthy and suspected animals are being inoculated at the same time. The animals supposed to be healthy should be first injected, and the needle (if it is necessary to employ the same needle) carefully sterilized by heating to a red heat or boiling in a 1-per cent. soda solution after the injection of each suspicious animal. 5. The thermometer should be sterilized in 5-per cent. carbolic-acid solution after the temperature of each horse is taken.

"Following an injection of mallein in a glandered horse, there will be a general reaction, with a rise of temperature and a local reaction. The temperature usually begins to rise three to four hours after the injection, and reaches its maximum between the tenth and twelfth hours. Sometimes, however, the highest point is not reached until fifteen or eighteen hours after the injection. This elevation of temperature is from 1.5° to 2° C., or even 4° C. above the normal mean temperature (i. e., 27° to 72° F.). In a healthy animal the rise of temperature, as a rule, amounts to only a few tenths of a degree, but it may reach a degree C. (= 1.8° F.), or a little more. The rise of temperature, however, should always be considered in connection with the general and local reactions. In a glandered animal, after an injection of mallein, the general condition is more or less profoundly modified. The animal has a dejected appearance; the countenance is pinched and anxious; the hair is rough and on end; the flank is retracted; the respirations are rapid; there are often slight or decided rigors; the appetite is gone. These symptoms vary greatly in different animals, but are never completely lacking. In healthy animals the general symptoms do not occur. The local reaction around the point of injection in a glandered animal is very marked. A few hours after the injection, there appears at this point a large, warm, tense, and very painful inflammatory swelling, and running out from the contour of this swelling will be seen hot sensitive lines of sinuous lymphatics, directed toward the neighboring lymphatic nodes. When the injection has been made aseptically, this swelling never suppurates. It, however, increases for twenty-four to thirty-six hours, and persists for several days, not disappearing entirely until after eight or ten days. In healthy animals, at the point of injection mallein produces only a small oedematous tumor, slightly warm and sensitive, and the oedema, instead of increasing, diminishes rapidly and disappears entirely in less than twenty-four hours. It is important to remember that the phenomena produced by mallein in glandered animals persist for a long time, the prostration continuing for from twenty-four to forty-eight hours, the temperature remaining above normal. If in any case the reaction obtained is only sufficient to cause suspicion of glanders (i. e., a rise of temperature of 0.8° to 1.1° C., or 1.5° to 2° F.), the injection of mallein should be repeated at the end of four or five days. Healthy animals seem to acquire an immunity to mallein, while glandered animals still react.

"Certain diseases, e. g., parvitis, often cause marked oscillations of temperature. When testing horses affected with such diseases, it should be noted after the injection whether the rise of temperature is persistent, and whether the general and local reactions are present. It is always better, however, when possible, to avoid injecting mallein in horses which already show an elevation of temperature. In acute glanders accompanied with high temperature, it sometimes happens that after an injection of mallein the

temperature does not rise a full degree. In other diseases, where the temperature is already high, there will generally be no elevation at all of the temperature, and there may even be a depression. The health department of New York especially requests that all veterinary surgeons who use mallein will forward full reports of the results obtained."

**Medical Education in Illinois.**—We have received a communication from Dr. J. W. Scott, the secretary of the State Board of Health of Illinois, in which, referring to Dr. Julius Grinker's letter, published in the *Journal* for July 25th, he says:

"Without discussing the merits or demerits of night schools or summer schools, the fact that Dr. Grinker connected himself with and remained for a year upon the faculty of a school which 'induces young and middle-aged men and women to leave the workshop and the stock yards where they slaughter cattle for the more remunerative occupation of slaughtering mankind' must, in the minds of fair-minded members of the profession, raise some question as to the sincerity of the motives which prompt his sudden solicitude for the cause of medical education."

Dr. Scott then gives a list of the members of the board and says: "No one acquainted with any of these members (and they are not unknown to the profession) believes that they would stretch the law in the interest of any institution or that they are less jealous of the good name and high standing of the Illinois State Board of Health than the gentleman . . . who, from whatever motive and without any knowledge of the workings of the board, made such an unwarranted attack. That the policy of such a board could be molded by its clerical officer is unworthy of any consideration whatever."

"Two statements in the communication of Dr. Grinker," says Dr. Scott, "are worthy of some attention as showing the personal prejudice and insincerity of the man. First, the statement is made that 'in the State of Illinois there are no recognized schools of midwifery. Every midwife must undergo a thorough examination before the Examining Board of the State (the State Board of Health). This means that the afflux of so-called midwives to the State is somewhat checked, as a large percentage of those applying for a license fail to pass their examination.' Dr. Grinker is not ignorant of the fact, though he does not mention it, that this result is largely due to the action of the present board in requiring of all applicants a *written* examination in place of the oral examinations previously conducted, and still further to the rule of the present board, which provides that all applicants who fail to pass the examination shall not be eligible for a second examination within a period of twelve months."

"Again, this statement: 'As long as the enforcement of those rules (preliminary educational requirements) rests with the school and not with the State board, the law is easily enough evaded.' Dr. Grinker is not ignorant of the fact that the Illinois State Board of Health, at the suggestion of its secretary, and working in harmony with the boards of Missouri and Iowa, have formulated and distributed to medical colleges of the country a new schedule of minimum preliminary educational requirements, by which the determination of the eligibility of the applicant to matriculate is taken out of the hands of the schools and practically determined by the State boards. Let each reader determine for himself why a friend of higher medical education should so pervert the facts."

"The statement that the secretary is a warm supporter of a movement to recognize certain schools of midwifery is totally false, as the records will show. On the contrary, the secretary has been and is in favor of requiring all applicants for midwifery certificates to pass a rigid *written* examination, and . . . does advocate the fixing of the minimum requirements for schools of midwifery as high as those for medical colleges."

"No college in Chicago has been accorded recognition by this board which has not first been investigated by a committee, of which the secretary is not a member, as to its teaching facilities, clinical resources, etc. The colleges referred to in Dr. Grinker's communication were all de-

nied recognition for several years and until they had complied with requirements established by the board, and will be deprived of such recognition, as has been repeatedly done, whenever it can be shown that they are violating those requirements. Dr. Grinker has filed written charges against the Harvey Medical College, which have been referred to a committee for investigation; but, for the reason that the board would not take summary action without giving the institution a chance to be heard in defense, has undertaken to excite prejudice against both the college and the board by rushing into print with a communication slandering both."

"Dr. Grinker's attempt to make his attack upon the board a plea for the establishment of a State examining board before which every applicant must appear and pass an examination, and thus curry favor with the most advanced advocates of higher medical education, will not, I think, deceive any. For that the establishment of such a law is the best solution of the question, and will ultimately be effected, I believe is the sentiment of the members of the Illinois board and certainly is of its secretary. But that the establishment of such a law is desirable can not in any degree justify a venomous attack upon a board which is doing its work courageously and conscientiously under the law which created it and by whose provisions it must be guided."

In a postscript, Dr. Scott says: "The reference to the annual announcement of the Illinois Health University, published in the *Journal* of August 1st, furnishes another evidence of the vigilance of the Illinois board in enforcing the medical laws of the State. Shortly after the organization of this institution, the attention of the attorney-general was called to its existence and character by the secretary of the board and suit was brought in the Circuit Court of Cook County, which resulted, on the 24th ult., in a decision by Judge Clifford revoking the charter of the institution on the ground of fraud."

**A Craze for Quackery in Paris.**—The following is taken from London dispatches to the *Sun*:

"Quackery has come to be more profitable than the legitimate practice of medicine with a large class in Paris. The other day a gentleman whose rooms are crowded from morning till night with patients was threatened with prosecution for exercising the profession without a diploma. Being thus brought to bay, he confidentially displayed to the officials the necessary document. He, however, implored the authorities to keep the diploma secret, explaining that if his clients had an inkling that he was a veritable physician his gains would diminish. M. Paul de Cassagnac makes even a more remarkable disclosure, and vouches for its authenticity. He asserts that there is a house in Paris in which patients are received for the purpose of undergoing sham operations. They have been induced to believe that they are suffering from some organic complaint which can only be cured with the knife, and they betake themselves to this establishment, which has been particularly recommended to them. On the day appointed for the so-called operation they are put under chloroform, and a few make-believe cuts and scratches are inflicted. In certain medical circles there is a regular name for men who practise these tricks on the victims of some imaginary ailment."

**An American Physician Honored in China.**—Under this heading, the *Lancet* for August 1st prints the following paragraph in its New York letter: "Dr. Boudinet Currie Atterbury, Presbyterian medical missionary to China, has been honored by the Emperor of China with the Imperial Order of the Double Dragon, Second Degree, a distinction never before conferred on any foreigner except the ruler of some friendly power. This mark is in recognition of the notable services rendered by the American physician in connection with the work of the Red Cross Society during the late war. Dr. Atterbury was born in New York city, and comes of a family long prominent in New York. He studied at Yale College, and took his medical course in this city under the direction of Dr. Frank H. Hamilton. After he graduated in medicine from Bellevue

Hospital Medical College, of the class of 1877, he went to China under the auspices of the Presbyterian Board, and was assigned to missionary duty in the city of Peking. He there assisted in the establishment of the Ah Ting Hospital. While there his work was brought to the attention of the Emperor and the royal family. He afterward went to Tientsin, where he is at present."

**Foreign Bodies in the Stomach.**—"It is said that a Yalta woman recently presented herself for treatment at an Odessa hospital. An operation was performed which, it is said, revealed the presence in her stomach of a strange assortment of objects, which were removed. It comprised a fork, a piece of iron, two teaspoons, a needle, a piece of lace with the crochet needle, two 24-inch nails, four pieces of glass, eight buttons, and a key."—*American Medical-Surgical Bulletin*.

**The Kentucky School of Medicine.**—Our latest information from Louisville is to the effect that Dr. Wathen "has entire control of everything included in the chair of obstetrics and gynecology," and Dr. Coomes has the same control as regards the chair of physiology, ophthalmology, otology, and laryngology.

**A Bit of Newspaper Medicine.**—One of the morning papers tells of a woman who was recently found lying in a salt marsh on Coney Island "unconscious" and "apparently suffering greatly."

**Army Intelligence.**—*Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from August 2 to August 8, 1896:*

CROSEY, WILLIAM D., Captain and Assistant Surgeon, Fort Missoula, Montana, is granted leave of absence for one month.

**Naval Intelligence.**—*Official List of Changes in the Medical Corps of the United States Navy for the Week ending August 8, 1896:*

BARBER, G. H., Passed Assistant Surgeon. Detached from the U. S. Steamer New York, ordered home, and granted leave of absence for two months.

MEANS, V. C. B., Passed Assistant Surgeon. Detached from the U. S. Steamer Maine and ordered to the U. S. Steamer New York.

## Births, Marriages, and Deaths.

### Married.

BARLOW—ANGELL.—In Providence, Rhode Island, on Tuesday, August 4th, Dr. Charles W. Barlow and Miss Florence A. Angell.

LORD—FORSATH.—In Rochester, N. Y., on Monday, August 3d, Dr. Matthias L. Lord and Miss Addie E. Forsath.

STICKLER—HARDING.—In Orange, New Jersey, on Thursday, August 6th, Dr. Joseph W. Stickler and Miss Mary Harding.

### Died.

CALLENDER.—In Nashville, Tennessee, on Monday, August 3d, Dr. John H. Callender, in the sixty-fourth year of his age.

CORTLEYNOT.—In Brooklyn, on Wednesday, August 5th, Dr. Lawrence V. Cortleynot.

PRIOLEAU.—In Summerville, South Carolina, on Friday, August 7th, Mr. Charles Edward Prioleau, son of Dr. William H. Prioleau.

ROSS.—In Pensacola, Florida, on Saturday, August 8th, Dr. William H. Ross.

## Proceedings of Societies.

### AMERICAN ASSOCIATION OF GENITO-URINARY SURGEONS.

*Tenth Annual Meeting, held in Atlantic City, on Tuesday and Wednesday, June 2 and 3, 1896.*

The President, Dr. CLAUDIUS H. MASTIN, of Mobile, in the Chair.

(Continued from page 167).

**Clinical and Pathological Notes on Syphilis.**—Dr. JOHN A. FORDYCE, of New York, read a paper on this subject in which the first portion was devoted to a description of the pathological appearance of the lesions met with in the various stages of syphilis. The second portion was devoted to the subject of *myositis syphilitica*. The author stated that, while involvement of the muscles in syphilis was by no means of frequent occurrence, it was met with in both the early and late stages of the disease. Before or during the outbreak of the early eruption, general or localized muscular pains not infrequently occurred, which simulated rheumatism and interfered to some extent with the movements of the implicated muscles. These muscular pains were transient in duration, produced, as a rule, no evident change in the parts, and readily disappeared under specific treatment. In the late secondary or tertiary period of the disease a diffuse or gummatous myositis had been observed. Both these forms impaired the functional activity of the muscles and led at times to permanent changes in the parts. The disease seemed to show a predilection for certain muscles or groups of muscles, among which might be mentioned the biceps, the flexors of the forearms, the masseter, the sphincter ani externus, the deltoid, and the sterno-cleido-mastoid. In diffuse syphilitic myositis the first changes seemed to take place in the blood-vessels of the interfibrillary connective tissue, the muscular substance being affected secondarily. In neglected cases, or where the cause was not recognized, atrophy might occur and a complete cure become impossible. A correct diagnosis and early treatment warranted a good prognosis as a rule. The speaker then reported a case of syphilitic myositis which occurred in the second stage of the disease. In this case the left sterno-cleido-mastoid had been affected. The case had occurred in the practice of Dr. P. A. Morrow. Another case was reported which illustrated the gummatous type of the disease; in that instance also the sterno-mastoid muscle had been involved. In the concluding portion of his paper, Dr. Fordyce reported in detail an interesting case of brain syphilis. Numerous photographs were exhibited in connection with the various subjects discussed in the paper.

Dr. Post said that during the past year he had seen two or three cases of myositis which clinically might be syphilitic, but which had occurred in individuals in whom no history of that disease had been obtainable, and there had been no other symptoms pointing to it.

**Clinical and Pathological Report of a Case of Cerebral Syphilis.**—Dr. GEORGE E. BREWER and Dr. PEARCE BAILEY reported the case of a man, aged twenty-five, single, who was first seen in the autumn of 1892. His family history was negative. Aside from a moderate amount of neurasthenia, he had always enjoyed fair health. At the time of his first visit he complained of headache, sore throat, deafness, ringing in the ears,

and general malaise. Upon examination, an indurated ulcer was found on the penis, with enlarged inguinal, cervical, and epitrochlear glands. There was a well-marked macular syphilide on the chest and abdomen; mucous patches were found on the tongue, lips, and tonsils; there was otitis media on the left side. Under the use of inunctions, continued for several months, followed by that of protiodide of mercury internally, rapid improvement in all his symptoms took place and he returned to his home in the South, where for a period of eighteen or twenty months he was under the care of another physician, who prescribed "mixed treatment." During all this period he remained well and was free from noticeable manifestations of the disease. About three years and a half after the date of the original infection he again came under observation, complaining of severe occipital headache radiating down the back and accompanied by occasional attacks of vertigo. The pain was severer at night, and was sometimes associated with nausea, vomiting, and extreme restlessness. Examination at this time revealed slight enlargement of the left pupil, beginning double optic neuritis, and a marked increase in all reflexes; no paralysis; no foot clonus; no changes in sensation; no loss of sphincter control. Under mercurial inunctions and increasing doses of potassium iodide, rapid improvement in all his symptoms occurred. On April 20th, after five days of freedom from headache and all abnormal head symptoms, he was suddenly seized with loss of consciousness and an epileptoid convulsion involving all the extremities. Ten hours later another slight convulsion occurred. He became restless, excited, and mildly maniacal. The temperature, which up to that time had been normal, now rose gradually to 104° F. The pulse remained below 100 and was firm and regular. There was no embarrassment of respiration. In spite of vigorous antisymphilitic treatment, he gradually sank into a comatose condition, and died on May 6th.

At the autopsy, made a few hours after death, the pia appeared normal over the convolutions, but at the base of the brain it was opaque and thickened. At the superior termination of the basilar artery, and inclosed by thickened meshes of the pia, was a round tumor, seventy-five millimetres in diameter. This tumor lay between the third nerves, slightly indenting the pons, on the lower surface of which it pressed, and the basilar artery communicated with it. The basilar artery was filled with a red thrombus throughout its entire extent, and the upper portion of the vertebrals and part of the posterior communicating arteries were likewise occluded. There was no softening. Microscopical examination showed endarteritis of some of the large arteries at the base of the brain and an aneurysmal dilatation of the basilar artery. The tumor referred to was formed by the dilatation of this artery, the walls of which were partially destroyed.

Dr. BAILEY referred to the rarity of cases of acute cerebral syphilis which afforded an opportunity for pathological investigation. The pathology of cerebral syphilis showed that the blood-vessels were the commonest seat of the lesions in fatal cases. It was not definitely known in which coat of the vessel the morbid process began, but the intima showed the most marked changes. It was impossible to distinguish, histologically, between specific endarteritis and endarteritis due to atheroma. The prognosis of acute cerebral syphilis depended upon the predominating anatomical character of the inflammation.

**Operative Interference in Aggravated Instances of Gonocystitis.**—Dr. EUGENE FULLER, of New York, read a paper on this subject in which the following conclusions were drawn: 1. Chronic, non-tuberculous cases could be successfully and satisfactorily treated by extirpation of the sac. 2. Such an extreme measure, however, should be reserved for extreme cases which were associated with serious or severe subjective symptoms. 3. Before extirpation was resorted to, the patient should have the benefit of the stripping treatment, if his circumstances allowed it, and extirpation should be advised only in case the stripping treatment proved unsatisfactory. 4. In performing the operation, the Kraske incision was the method advisable. 5. The subjective symptoms associated with the disease ought to disappear as a result of the operation. 6. With but one seminal vesicle, provided it was healthy, the sexual function was strong and satisfactory. 7. Subacute epididymitis was to be expected after the operation, in connection with the testicle corresponding to the vesicle which had been removed. The testicle itself, however, did not subsequently become atrophied.

Dr. GEORGE CHISHMORE, of San Francisco, said he fully agreed to the statement made by Dr. Fuller that before undertaking any operation on the prostate or seminal vesicles, tuberculosis of that region should, if possible, be excluded. The speaker said he had thus far never resorted to operative measures in the treatment of gonocystitis; in a number of cases, however, he had seen marked benefit follow stripping the vesicle, after the manner suggested by Dr. Fuller.

Dr. GARDNER W. ALLEN, of Boston, exhibited a specimen composed of inspissated mucus which had been passed during urination, and probably had had its origin in one of the seminal vesicles.

Dr. JOHN P. BRYSON, of St. Louis, said he agreed to the statement made by Dr. Fuller that with the Zuckerkandl incision the field of operation was so limited that it was difficult to control the severe hemorrhage which was apt to occur, while the rectum or bladder or even the deep urethra was easily injured.

Dr. J. WILLIAM WHITE, of Philadelphia, reported a case of gonocystitis of long standing which had been entirely cured by the stripping method of treatment. In tuberculous cases, the speaker said, he confined himself to hygienic treatment, which was probably all that could be done.

Dr. A. T. CABOT, of Boston, said he was interested to learn how easily Dr. Fuller had been able to get at the seminal vesicles by means of the Kraske incision.

Dr. FULLER said he agreed with Dr. White that hygienic treatment was the only resort there was in cases of tuberculous origin. By operating in such a case we were apt to light up latent foci there and induce a rapid dissemination of the disease.

**Renal Tuberculosis.**—Dr. F. TILDEN BROWN, of New York, read a paper with this title. He stated that but three ways were known in which the tubercle bacilli might gain access to the kidney. These were: 1. By the blood. 2. By their multiplication and the gradual development of tuberculous granulations along the ureter from the bladder—ascending urinary infection. 3. By an extension of the disease from a neighboring or remote organ.

A summary of the different symptoms and evidences which had been advanced as in any way conducive to the diagnosis of renal tuberculosis, whether vascular or ascending in origin, would be fairly represented by the

following: The existence of a tumor which corresponded more or less accurately to the position of the kidney. Such a tumor might or might not be painful on palpation, or it might be the seat of spontaneous pain, often intermittent. The tumor might be a centre from which pains radiated to different parts of the abdomen, to the lumbar spine, down the groin, to the outer side of the thigh, or even to the opposite and healthy kidney. Again, without the presence of a tumor or an appreciable enlargement of the kidney, some of the following symptoms, which were mentioned in the order of their importance, might be noticed: Pallor and emaciation; cedema of the feet and legs; reaction to the injection of tuberculin; albuminuria; moderate pyrexia; night sweats; dysuria; pyuria, with acid urine; hæmaturia with acid urine; polyuria; frequency of urination; turbid urine seen by the cystoscope issuing from a ureter; and the finding of tubercle bacilli in that urine which was known to come from one or the other kidney, as when obtained by ureteral catheterism. The only micro-organism which could possibly lead us astray in the microscopic diagnosis was the smegma bacillus. The morphology of this parasite, as well as its similar reaction to the ordinary staining method for the tubercle bacillus, might, when it was present, easily be misleading, unless generous alcoholic decolorization was employed.

The symptomatology of renal tuberculosis was very important, because the physician who could make a positive diagnosis in a comparatively early stage of the disease rendered more valuable service than the surgeon did who, at a much later day, performed a successful nephrectomy.

As regarded the treatment of patients with renal tuberculosis, the rich would, as a rule, find their best resource in change of climate, careful attention to hygienic details, selected alimentation, and medicinal invigoration of the system. The poor, during the early stage of the disease, would receive the greatest benefit from a treatment which approximated as nearly as possible that advocated for their more fortunate fellow-sufferers. Theoretically, the earliest manifestation of a localized renal tuberculosis would be best treated by a radical surgical operation, but practical experience had pretty clearly shown that the temporary impairment of vitality attendant upon nephrectomy was of more disastrous import than the presence of an early tuberculous lesion and the bacilli causing it. On the other hand, if the lesion in the kidney was recognized comparatively early, it could by other than surgical measures, in many cases, be rendered so inactive as to approximate a cure. In exceptional cases, when the symptoms demanded it, nephrectomy was not only legitimate, but strongly indicated.

Dr. FRANCIS S. WATSON, of Boston, referred to the intermittence of the symptoms in many cases of renal tuberculosis. He also called attention to the value of resection or partial nephrectomy in some instances, and reported a case in which he had successfully removed the lower half of one kidney, which had been involved in tuberculosis.

Dr. WHITE, discussing the relative value of the lumbar and abdominal incision for nephrectomy, said that until last year he had been a strong advocate of the former. He had been induced to alter his opinion because the lumbar incision did not give the operator the necessary space. The operation of partial resection suggested by Dr. Watson seemed to him a very formidable one—more so than complete nephrectomy.

Dr. CHISMORE said that Dr. Brown, in his paper,

spoke of catheterizing the ureters in order to discover the origin of the tubercle bacilli. Such a procedure, Dr. Chismore said, or even the simpler one of cystoscopy, should be resorted to with considerable hesitation in any case where tuberculosis was suspected, as we were apt to aggravate the symptoms. When we considered the fact that in many cases of renal tuberculosis the origin of the trouble was associated with traumatism, how much more likely it was that any trauma inflicted afterward would aggravate the condition and tend to disseminate the disease.

Dr. JAMES BELL, of Montreal, referred to the importance of determining the condition of the opposite kidney before operating in cases of renal tuberculosis. In performing nephrectomy he preferred the abdominal incision because it might throw some light on the condition of the opposite kidney, and also because it enabled us to secure the pedicle with more confidence than the lumbar incision did in some instances.

Dr. BRYSON said he had come to the conclusion that there was no such thing as a symptomless renal tuberculosis. Before undertaking any operative measures in these cases we must bear in mind how frequently this condition was only a local manifestation of a general disease. He agreed with Dr. White that complete nephrectomy was preferable to resection, as suggested by Dr. Watson.

Dr. N. B. CARSON, of St. Louis, referred to the danger of interfering in localized tuberculous trouble. To illustrate this, he reported the case of a young woman who for many years had had a localized tuberculous lesion in one knee-joint. She entered a hospital, where the joint was opened and everted; soon afterward it became necessary to amputate the leg above the knee, and about six weeks later the patient died, presumably from acute tuberculosis.

Dr. BROWN said that local interference should be undertaken in renal tuberculosis only when it was absolutely called for, and then only with the greatest care. He expressed the opinion that if there were adhesions, the abdominal, intraperitoneal, route was preferable; otherwise, he was inclined to favor the lumbar route. He did not think the abdominal incision would be of much service in determining the condition of the opposite kidney.

**Some Forms of Non-obstructive Ischuria.**—Dr. ALEXANDER W. STEIN, of New York, stated that inability to empty the bladder might be due to: 1. Atony of its muscular parietes. (a) Deficient contractile power of the so-called detrusor from overstretching of its fibres; the duration was usually temporary. (b) Loss of power of the detrusor from atrophy and fatty metamorphosis; the duration was permanent. 2. Neurotic retention. (a) Deficient power of the detrusor as a concomitant of some psychical or functional disturbance of the nerve centres; the duration was temporary. (b) Paresis or cystoplegia from organic derangement of the nerve centres; the duration was usually permanent. 3. Spastic or reflex retention from irritation of some neighboring organ; it disappeared with the cause that induced it.

The degree of atony which resulted from overdistention of the bladder might vary from a slight and temporary impairment in the expulsive power of the organ to a complete and permanent inability to empty its contents, depending upon the age and health of the person, the condition of the bladder, the degree of distention, and the length of time the detrusor fibres had been upon the stretch. In the aged and feeble this condition was

not uncommon, and permanent disability of the viscus often results from a single inattention to its behests. In the young and robust atony was much less frequent, and the bladder, once relieved of its burden, regained its functional activity. Dr. Stein reported a number of cases of atony of the bladder which had come under his observation.

**Two Cases of Prostatectomy. Prostatectomy after Castration.**—Dr. JOHN P. BRYSON, of St. Louis, reported these cases. The first case was one of prostatic overgrowth in a man, eighty years of age, who, forty years before, had had an attack of mumps which had been complicated by an orchitis which completely destroyed the left testis. The right testis was normal in size and consistence. Prostatectomy was performed on July 18, 1895. The operation disclosed the fact that the left lobe of the prostate (which was the one corresponding to the atrophied testis) was larger than its fellow. The largest mass of prostatic tissue was removed from the left side.

The second case reported was one where prostatectomy had been done a year after double orchidectomy for prostatic overgrowth. The patient was a man sixty-four years of age. Double orchidectomy was performed on April 8, 1895. On the sixth day after the operation the patient reported that he felt better. He continued to use the catheter until the end of June, when there was only a small quantity of residual urine. He had gradually regained the power of voluntary urination, and had no longer been troubled with nocturnal frequency. The bladder had been irrigated once daily, at bedtime. On January 20, 1896, he had an attack of complete retention and he again became entirely dependent upon his catheter. An examination of the prostate made on April 30, 1896, failed to reveal any change in its size, shape, or consistence. The urine had become decidedly purulent, and the walls of the bladder were inflamed and showed numerous small pockets, one of which had contained a calculus. On May 1, 1896, suprapubic cystotomy was performed, and the calculus removed, together with a large mass of prostatic tissue. The patient made a satisfactory recovery from the operation, but on May 26th he died suddenly of a mitral lesion. In that case the prostate had not been reduced in size by the castration which had been done twelve months previously, and a microscopical examination of it had failed to show any evidence of degenerative changes. Dr. Bryson exhibited a number of gross and microscopical specimens.

Dr. WHITE said the case reported by Dr. Bryson formed a valuable addition to the knowledge of what were gradually acquiring as to the certainty or uncertainty of the result of castration for enlarged prostate. When he had introduced this operation he had done so cautiously and with the hope that it would not be indiscriminately performed. We must study our cases carefully, and decide which were favorable for castration and which for prostatectomy. The speaker expressed the opinion that the operation of castration for enlarged prostate had come to stay, and that there would always be cases suitable for it.

Dr. CABOT said that in the beginning, at least, the operation of castration for prostatic overgrowth had been performed too promiscuously, in spite of the fair manner in which Dr. White had presented the subject. It was very important that we should arrive, as soon as possible, at a clear understanding of the fact that the operation was not a trivial one, as had at first been believed.

The speaker expressed the opinion that the mortality was due to the condition there was to deal with, and the question in a given case was, Which operation would relieve the condition with the least added danger, castration or prostatectomy? The drainage which was instituted after prostatectomy immediately relieved the bladder and the kidneys, while after castration the relief was more gradual. The kidneys might stand the strain or they might not, and this was probably the chief factor in the fatal cases that had occurred. Another factor was that the testes no doubt exerted some tonic influence on the nervous system, and the cases of mania that had been reported following the removal of these organs had probably been due to this fact. Dr. Cabot had expressed the opinion that shrinkage of the prostate after castration was an established fact. It was difficult to understand what changes occurred in the organ, as the microscopical examinations thus far made had proved very unsatisfactory.

Dr. FULLER said it would be interesting to ascertain just what constituted prostatic hypertrophy. He had noticed that in some cases the prostatic tissue was enucleated very readily, while in others it was a difficult matter to remove it.

Dr. BELL said that the more we discussed the subject, the more clearly were we brought face to face with the fact that the immediate cause of death in all these prostatic patients, no matter which operation was performed, was a form of toxæmia. This toxæmia, which was probably responsible for the mental symptoms and the mortality, was something about which very little was known.

**The Duration of Acute Gonorrhœa.**—Dr. H. M. CHRISTIAN, of Philadelphia, read a paper on this subject, in which he stated his conclusions as follows: 1. Gonorrhœa was a more prolonged and serious disease than it was generally considered. 2. In two thirds of all uncomplicated cases the period of time necessary to effect a cure was from six to ten weeks. 3. In that small proportion of cases where the entire urethra did not become involved, the disease being confined to the anterior urethra, we could expect a complete recovery in four weeks. 4. It was important to make an examination of the urethra before pronouncing a gonorrhœa positively cured.

Dr. WILLIAM JUDKINS, of Cincinnati, said that Dr. Christian's paper would prove of interest both to the specialist and to the general practitioner. It was astonishing in how brief a period of time some physicians could cure gonorrhœa, judging by their own statements. He had heard of one man who alleged that he cured the disease in ten days with bicarbonate of sodium.

## SOCIETY OF ALUMNI OF BELLEVUE HOSPITAL.

*Meeting of April 1, 1896.*

The President, Dr. PARKER SYMS, in the Chair.

**Malignant Pustule of the Face.**—Dr. J. F. ERDMANN presented a case of this kind (see page 213).

**Two Cases of Traumatic Aneurysm Treated by Ligation and Extirpation of the Sac.**—Dr. J. S. HOWELL reported the cases (see page 215).

Dr. ERDMANN said that he had been reminded by the first case reported of one he had seen at the workhouse—in a man who had received a punctured wound of the femoral artery and vein. This had resulted in an arterio-venous fistula, with an aneurysm of the size of a small

egg. It had gradually increased in size, and finally the femoral artery had been ligated by him both above and below the aneurysm. This had been followed by gangrene, and still later by amputation and death. He was therefore anxious to know why Dr. Howell had ligated both the vein and the artery.

Dr. HOWELL replied that both the vein and the artery had been completely perforated, hence he had felt compelled to ligate the vein also. As the two wounds were opposite to each other, a lateral ligature would have been likely to unduly occlude the calibre of the vein. Still another reason was that considerable time had elapsed since the injury, and therefore there had been ground to believe that some collateral circulation had been already established.

**Pulmonary Hæmorrhage** was the subject of a discussion by Dr. R. J. CARLISLE (see page 216), Dr. JOHN WINTERS BRANNAN (see page 218), and Dr. CHARLES E. QUIMBY (see page 154).

Dr. J. WEST ROOSEVELT said that he should be compelled to disagree with a number of statements that had been made, and in doing this he would endeavor to point out certain important facts connected with the physics of the lungs. When he had begun the study of this subject, about nine years ago, he assumed that all were acquainted with the distribution of the blood through the lungs, but he had been astonished to find that there was nothing in English, French, German, or Italian bearing upon this subject prior to the work of Hewitt, published in 1890. The anatomy of the pulmonary blood-vessels between the main divisions of the pulmonary arteries and veins and the alveoli had been an unknown field up to that time. Dr. Roosevelt then presented a beautiful corrosion specimen illustrating the distribution of the blood through the lungs, and also a specimen of lung which had been rendered transparent by first bleaching it with peroxide of hydrogen and then filling it with a mixture of oil of cedar and oil of cloves—in other words, with a substance having the same index of refraction. This latter specimen was interesting as it illustrated the remarkable ramifications of these blood-vessels. One of the bronchi in the specimen had been filled with air so as to indicate the amount of tissue in which extravasation of blood might occur. What happened in most cases of hæmoptysis was a purely bronchial hæmorrhage. It could be easily understood how much blood could be lost in this way when one recalled the amount of blood that could be lost by diapedesis in cases of hæmorrhage from the nose. It was well known that many cases of pulmonary hæmorrhage were not followed by serious symptoms. It was unsafe to make a diagnosis of phthisis until at least a week had elapsed after such a hæmorrhage. The hæmorrhage from a bronchus sometimes filled part of a lobe with blood, thus giving rise to the physical signs of phthisis or of pneumonia. It was also accompanied by fever, and other symptoms of constitutional disturbance. In the majority of cases of initial hæmorrhage the hæmorrhage itself was not of great importance; there was far more danger of injuring the patient by too active treatment of the hæmorrhage than from the hæmorrhage itself. A case of hæmoptysis, even to the extent of a drachm, in an adult who had had a cough that had not begun with a coryza, and that had been associated with clear or whitish expectoration, with slight dullness and change of respiration at one apex, was almost certainly tuberculous, provided mitral disease and aortic aneurysm could be excluded. On the other hand, there might be quite a

profuse hæmoptysis in a person without previous cough or expectoration. Here one must not trust too much to the physical signs, and should not form an opinion as to the significance of the condition until some little time had elapsed. He could not say that from actual careful observation we were justified in assuming the correctness of the theory that there were small aneurysms in the blood-vessels of the lungs, or that hæmorrhage from a bronchus indicated vascular degeneration, or anything else than tuberculosis. Above all, he could not say that the mechanical cure suggested for it by Dr. Quimby presented the true physical conditions. During expansion of the lung the artery was drawn down longitudinally and more or less compressed, and the pressure was removed from the vein as the lung expanded, even though a positive pressure were brought to bear upon the lung. The pressure on the outside of the body might be reduced to a considerable extent, yet the pressure on the lungs would still remain fifteen pounds to the square inch; reduction of pressure never did more than affect the differential pressure. The lungs, whether expanded little or much, reacted just sufficiently to counterbalance the pressure of the atmosphere—i. e., fifteen pounds pressure to the square inch. In incipient phthisis, in cardiac disease, or in any condition not associated with cavities in the lungs, or with aneurysms, the hæmoptysis was rarely of itself of much importance. In the other cases where there was a hæmorrhage into a cavity, there was no power which could alter the fate of that patient. It was not to the hæmoptysis itself, but to the condition which it represented, that our attention should be especially directed. Pulmonary hæmorrhage seemed to him of interest more because of its diagnostic and prognostic importance than from its significance *per se*. Regarding pulmonary infarctions, he said that the wedge-shaped area would always be produced in animals if the lung were slightly torn with a dull needle, and a little hæmorrhage thus produced. This simply meant that the blood had been effused around one large branch of a bronchus.

Dr. EGBERT LE FEVRE said that in considering the causes of hæmorrhage, the text-books usually took into consideration the effect of vascular tension. It was generally noted that patients who previous to the tuberculosis had suffered from certain diatheses were apt to have hæmorrhage. Sir Andrew Clark had first called attention to this, as a result of observations on hæmorrhages occurring in old people who were free from tuberculous and cardiac disease. This he had attributed to an "arthritic diathesis" with changes in the blood-vessels. Many of the patients having hæmorrhage had given marked evidence of rheumatism prior to the development of the tuberculosis. The anemia coming on in the early stage of tuberculosis caused changes in the blood-vessels which predisposed to hæmorrhage. He had been greatly interested in the specimens presented by Dr. Roosevelt. It was a singular thing that cough and expectoration were not observed in cases of cardiac disease so long as there was a compensating hypertrophy in the right heart, but that these symptoms developed as soon as the compensation was incomplete. The anatomy of the blood-vessels apparently offered a plausible explanation of this fact. In two cases of fatal initial primary hæmorrhage that he had seen, in which there had been slight physical signs, the condition of the lung had been that of a pulmonary infarction, and the blood had apparently come from the small vessels, and not from the large vessels situated in the bronchi. Regarding the

treatment, the speaker said that where the hæmorrhage was due to erosion or rupture of a large vessel stretching across a cavity, he knew of nothing but Nature's effort at lowering arterial tension which was likely to be of much service. Where the hæmorrhage was from the smaller vessels he was accustomed to use the opium treatment, and also to reduce the arterial tension to as low a point as seemed safe. For this purpose he gave aconite in repeated doses until the desired effect had been produced. He would like to ask whether Dr. Roosevelt had found that the relation between the tension of the general systemic circulation and that in the pulmonary artery corresponded. Experiments had been carried on to show that the equilibrium of the pulmonary circulation could be disturbed with difficulty, although there might be a marked change in the systemic circulation. If this was true, it certainly excluded a number of drugs that had found much favor in the treatment of pulmonary hæmorrhage. The tendency of primary attacks was to arrest or recovery.

Dr. ROOSEVELT said that he could not reply definitely to the question just propounded, for he had made no researches in that direction.

### Book Notices.

*The Fundus Oculi.* With an Ophthalmoscopic Atlas illustrating its Physiological and Pathological Conditions. By W. ADAMS FROST, F. R. C. S., Surgeon to the Royal Westminster Ophthalmic Hospital, etc. Edinburgh and London: Young J. Pentland. New York: Macmillan & Co., 1896. Pp. xviii-228. [Price, \$18.]

MR. FROST has here given to the medical profession a work which is a pleasure to look upon and an equally great pleasure to read. The book is a folio of two hundred and twenty pages of letterpress, illustrated by forty-six figures in black and white, of exquisite workmanship, representing macroscopically and microscopically those parts of the eye which we see with the ophthalmoscope. Bound up in the same volume are forty-seven large colored plates, containing one hundred and seven figures, beautifully drawn and colored, representing the fundus of the eye as seen with the ophthalmoscope.

The work is divided into two parts, physiological and pathological, and an unusual amount of space has been devoted to "physiological variations." The drawings of the fundus are admirably adapted for teaching purposes. They have all been executed from Nature by an artist, under the direct supervision of Mr. Frost, and, with the exception of one plate, were all made by the direct method of examination and by artificial light. The unit for the standard of measurement chosen is the diameter of the optic disc. To facilitate measurements of this kind, the author has designed a fundus-gauge, consisting of a rectangular network of fine wires which, when attached to an ophthalmoscope, throws its shadow on the fundus, thus mapping it out into squares.

Part I is devoted to a consideration of the subject of physiological variations, including developmental irregularities. It fills eighty-four pages of the text and is divided into five chapters.

The first chapter treats in a general way of the normal fundus, including sclera, chorioid, and retina.

The second chapter treats of the optic disc in all its relations.

The third chapter considers the retinal vessels.

The fourth chapter describes the macula lutea.

The fifth chapter describes the various developmental irregularities.

This physiological part is illustrated by numerous black and white illustrations, and by fourteen large colored plates with thirty-nine figures. Considerable space is given to a consideration of the subject of the normal pigmentation of the fundus, with its many irregular variations. The chapters on the normal disc and retina are very full, and the description of the method of formation of coloboma of the chorioid is very clear. The author calls special attention to what he calls "congenital crescent of the disc," and thinks it due to an uneven distribution of the tissue of the lamina cribrosa. He thinks this condition is sometimes erroneously considered as a coloboma of the chorioid, which term should be confined to those extreme types which depend on non-closure of the cleft at the lower part of the nerve in foetal life. Fig. 34, on page 82, might easily be mistaken for a glaucomatous excavation of the disc.

Part II is devoted to a consideration of the pathological conditions of the fundus, and a large space is devoted to affections of the chorioid. Mr. Frost calls attention to the discrepancy which exists between the number of vessels in its tissue and the number of the ciliary arteries which supply it, and makes the point that its circulation must be sluggish. He thinks this explains the great liability of the chorioid to degenerative processes and chronic inflammation. The author's remarks on "choked disc" are interesting and instructive. He thinks that pathological evidence is against the theory of venous obstruction behind the globe or of compression exercised by the scleral ring, and believes that the venous obstruction is secondary to inflammatory changes in the disc, and that the pressure is exercised by the inflammatory products within the head of the nerve.

The author's remarks on retinal hæmorrhages, on page 168, are open to criticism, especially with reference to the condition of the blood-vessels outside the eyeball. *Per contra*, on page 174 there is an admirable distinction made between arterial embolism and arterial thrombosis, though the ophthalmoscopic signs may be identical. In embolism, the subject of collateral circulation has always excited great interest and has given rise to much discussion. It has been repeatedly inferred from clinical evidence, but it has never been proved to exist post mortem, and Mr. Frost is inclined to doubt its existence. In discussing the subject of thrombosis of the retinal veins, the author again brings up the matter of papillitis by asserting that it is often caused by thrombosis.

Chapter XI contains a most excellent description of the various punctate conditions of the fundus which have at different times been described by authors, such as Tay, Gunn, Nettleship, Mooren, Masselon, and others. A brief account is also given of the so-called "angioid streaks" of the retina, illustrated by two perfect black and white pictures.

The colored plates are extremely well drawn and printed and are a noble complement to the work.

The publishers have outdone themselves in their part of the publication. The paper is thick and heavy and but slightly glazed. The type is beautifully clear and as large as No. 9 of Jaeger's test types, so that literally "he who runs may read." Mr. Frost is to be congratulated upon the manner in which he has done his part.

Such a work must of necessity be expensive, and the price of the book must make the number of readers limited.

*A Text-book of Bacteriology.* By GEORGE M. STERNBERG, M. D., LL. D., Surgeon General, United States Army, Honorary Member of the Epidemiological Society of London, etc. Illustrated by Heliotype and Chromolithographic Plates and Two Hundred Engravings. New York: Wood & Company, 1896. Pp. xi+693. [Price, \$5.50.]

THIS text-book, justly recognized as the leading treatise upon this subject in the English language, has been extensively revised, curtailed in some departments and extended in others, and now, in its second edition, most admirably adapts the advances in bacteriology to the wants of students and practitioners, and meets equally well the requirements of pathologists. The extensive tables prepared in the first edition for use in bacteriological diagnosis have been omitted. Without denying the value of these tables as seen in the first edition it may justly be said that they were insufficient for the identification of many species. A short practical experience in bacteriological diagnosis would convince any one that the separation of species requires, in the majority of instances, minute and extensive descriptions of biological properties, and that these alone will fill a large volume.

Other chapters have been correspondingly enlarged, and in a volume of less bulk and of less expensive preparation the entire subject is most completely presented.

Bacteriological technics is the subject of one hundred pages in which the newer culture media and bacteriological apparatus are fully described and illustrated.

A considerable section is devoted to the photography of bacteria, and the methods and apparatus are described by which the striking advance of the last three years in this branch have been achieved.

Important additions have also been made in the second part, on general biological properties of bacteria.

The chapter on susceptibility and immunity has been largely revised to incorporate the results of extensive researches of the past four years, and undoubtedly presents one of the ablest short discussions of this obscure and important subject anywhere to be found. The theory of phagocytosis is more fully discussed than before, and the views of Metchnikoff are reproduced at length. It will be seen from the following quotation from Metchnikoff's conclusions and the author's comment thereon that the evidence of recent investigations has permanently established the partial truth of the phagocytic theory:

"It is not possible at the present time to state fully and accurately all the influences which are associated in aiding phagocytic action, but already we have the right to maintain that in the property of its ameboid cells to include and to destroy micro-organisms, the animal body possesses a formidable means of resistance and defense against these infectious agents." We are disposed to agree with Metchnikoff in his final conclusion as above stated in italics. But in view of experimental evidence to be referred to later, we can not accept the so-called Metchnikoff theory as a sufficient explanation of the facts relating to natural and acquired immunity in general, and must regard phagocytosis simply as a factor which in certain infectious diseases appears to play an important part in enabling immune animals to resist invasion by pathogenic bacteria."

The "further experimental evidence" above mentioned refers to the immense number of isolated facts now accumulated in regard to the immunity against and the disposal of bacterial and chemical poisons in the organism, problems to which the phagocytic theory is at present an imperfect solution.

In the discussion of the pathological properties of well-known species, it would seem that the author has incorporated every important research of the past few years up to the date of going to press. For instance, Elsner's method of diagnosis of the typhoid bacillus is described, and even more recent experiments supporting Elsner's statements and the reliability of his method are reported. The very important work of Janousky on the pus-producing capacity of many species recently regarded as non-pyogenic is duly emphasized. The descriptions of other pathogenic species are equally complete, with reference to very late publications. Less common pathogenic species are fully described, as before, and a considerable number of recently discovered forms have been added.

Several new photomicrographs and lithographic plates, all of which are very successfully executed, greatly add to the effectiveness of the descriptions.

It is everywhere apparent that the revision of this work, equally with its original production, shows the high scholarship and ability of the author.

Not only does it fulfill the requirements of the bacteriologist, but no practitioner can consider himself abreast with the times without familiarity with the contents of several of its chapters.

The work can therefore be recommended without reserve to all classes of readers.

*Borderland Studies.* Miscellaneous Addresses and Essays pertaining to Medicine and the Medical Profession, and their Relations to General Science and Thought. By GEORGE M. GOULD, A. M., M. D., etc. Philadelphia: P. Blakiston, Son, & Co., 1896. Pp. 11 to 384. [Price, \$2.]

IN this most attractive volume, Dr. Gould has given his many friends and admirers an opportunity to spend a few hours of delightful reading. The contents of the book consist of editorials from the *Medical News* and of addresses and essays read before societies and published in reviews. They are characterized by the honesty of purpose, the love and zeal for professional integrity, the admiration for system in nature with which Dr. Gould's readers have long been acquainted and which they always expect from him. In his essays there appear that same fearlessness and chivalry, that striving for improvement, and that longing for health in the body politic and professional that have ever marked his editorial utterances. Dr. Gould brings us very near to nature and to ourselves, and it is largely the truth of his writings and the incisiveness of his pen that lend a charm to the essays under consideration. In his condemnation of fraud and trickery there is none more bitter, in his praise of the true and good none sweeter, than Dr. Gould. If it is possible, *Borderland Studies* can only enhance the author's reputation as a student, as a thinker, and as a writer.

*A Manual of Anatomy.* By IRVING S. HAYNES, M. D., Ph. B., Adjunct Professor and Demonstrator of Anatomy in the Medical Department of the New York University, etc. With One Hundred and Thir-

ty-four Half-tone Illustrations and Forty-two Diagrams. Philadelphia: W. B. Saunders, 1896. Pp. 11 to 680. [Price, \$2.50.]

A MANUAL of anatomy for the use of students in the dissecting room should consist of a brief but accurate description of all the structures which can be seen by the dissector, arranged in the order of their dissection, together with a full description of the best method of exposing each structure and preserving its normal relations. In this Dr. Haynes has been most successful. The arrangement is excellent and the descriptions are brief, clear, and forcible. He is especially to be congratulated on his able presentation of that most difficult subject, the peritonæum. By a judicious reference to the development of this membrane he is able to explain many points always difficult of comprehension and never thoroughly understood by many students.

Another desirable feature, however, of such a manual, and one which is thoroughly appreciated by all beginners in the study of anatomy, is a judicious selection of clear, sharp, and well-defined illustrations which exhibit in the most striking manner the structures and their relations. In our opinion, this can never be accomplished by the reproduction of photographs. The dissections from which many of Dr. Haynes's photographs were made were evidently prepared with the greatest care and give evidence of skillful and painstaking work, yet for the use of students they are vastly inferior to the cuts found in Gray or Quain. Although the experienced eye might be able to recognize the different structures shown in Figs. 82, 83, 86, 126, and 127, for instance, they are certainly too indistinct to convey much to the mind of a student making his first dissection.

*Quain's Elements of Anatomy.* Appendix: Superficial and Surgical Anatomy. By Professor GEORGE D. THANE, of University College, London, and Professor R. J. GODLEE, M. S. Illustrated by Twenty-nine Engravings. Tenth Edition. London, New York, and Bombay: Longmans, Green, & Co., 1896. Pp. 76.

THE editors of Quain's work have endeavored, in their tenth edition, to present to the medical profession the most comprehensive and exhaustive treatise upon the subject in the English language. The work, however, would have been incomplete had they omitted to prepare their recently published appendix on Superficial and Surgical Anatomy. In this small volume they have ably and concisely presented the important facts bearing upon the subject, leaving out a large amount of unimportant material usually included in a treatise of this kind.

In fact, the only criticism which can justly be urged against the work is that it is at times so abridged as to be almost defective. In the section, for instance, devoted to the surgical anatomy of the mastoid, it seems to us that the editors should have added a paragraph describing the variations from the normal adult conditions found during childhood and early youth, periods at which disease of the mastoid requiring surgical interference is especially prevalent. The chapter on the neck also might with advantage be somewhat amplified. Had the editors added a few words on the blood supply and the relations of the thyroid gland, it would have been appreciated by the young tracheotomist or the surgeon about to undertake his first thyroidectomy.

The chapter devoted to the structures found in the

groin and the descriptions of the surgical anatomy of inguinal and femoral hernia are especially to be commended. Several new and excellent cuts have been introduced which clearly illustrate the facts brought out in the text.

The structures of the perinæum in the male receive appropriate attention, and a short chapter is added upon the examination of the pelvic viscera in both sexes.

The book is well arranged, well written, and well illustrated. It is a valuable and practical conclusion of an excellent work.

*Sterility.* By ROBERT BELL, M. D., F. F. P. S. G., Senior Physician to the Glasgow Hospital for Diseases Peculiar to Women. London: J. & A. Churchill, 1896. Pp. vi-9 to 88. [Price, \$1.75.]

THIS monograph can not be seriously regarded except in so far as it expresses the individual views of the writer, which are in many respects opposed to the belief generally prevailing. Unquestionably the author is correct in attributing sterility in many cases to endometritis, but he vitiates his position by refusing to acknowledge the rôle that flexions play in the production of catarrh of the uterine mucous membrane. Though he admits that stenosis of the internal os frequently coexists with a sterile condition, he is unwilling to acknowledge that dilatation may be followed by pregnancy, attributing, as he does, the narrowing of the canal to endometritis. In this respect the author's position makes one believe that his logic is deductive rather than inductive.

The chapters on dysmenorrhœa and diseases of the uterine annexa are well written and conservative, but the discussion of curetting is calculated to produce an impression of tremendous hazard in the performance of this operation. It may be well to remark that Bell does not regard the ovule—or "ovum," as he calls it—in the usually accepted physiological light. He believes that the "ovum" has for its sole function the providing of the only pabulum upon which the spermatozooids can possibly subsist, and that it is the male element, thus endowed and nourished, which develops into the embryo. This new assumption of prerogative on the part of the male is worthy of the consideration of a woman's suffrage convention.

The bookmaking is fair and the proofreading excellent; but the monograph is not destined, despite its author's position, to attain scientific prominence.

*Elementary Anatomy and Surgery for Nurses.* A Series of Lectures delivered to the Nursing Staff of the West London Hospital. By W. McADAM ECCLES, M. S. Lond., F. R. C. S. Eng., Assistant Surgeon to the West London Hospital, etc. London: The Scientific Press, Limited, 1896. Pp. xv-158. [Price, 2s. 6d.]

THIS little volume consists of the substance of a course of lectures delivered by the author to the nurses of the West London Hospital. While many of the salient points of these subjects are taken up and ably discussed, there is a conspicuous absence of much information which it is highly essential that a well-trained surgical nurse should possess.

The book would have been much more useful had more space been devoted to methods of preparing sterilized dressings and ligature and suture material, and less to the origin of the spinal nerves and minute descriptions of the organs of special sense.

## Miscellany.

**The Continued Fever of Jerusalem.**—The *Lyon médical* for July 19th contains an article on this subject by M. Friess, who remarks that one of the many curious facts which attract the physician's notice on his arrival in Jerusalem is the frequency of intermittent fevers. The city is situated on a plateau which overlooks the surrounding country, at an elevation of twenty-six hundred feet; there is no stagnant water around the city, there is a complete absence of verdure and water courses, and there are dryness and desolation everywhere. Under these circumstances, says the author, the origin of the malarial troubles which exist all the year round, especially during the dry season, which lasts from April to December, can be attributed only to the cisterns, which are rendered necessary by the absence of water courses. These cisterns catch the water which falls from the roofs and the terraces during the rainy season, and they contain a large number of foreign bodies carried into them by the wind. The question, says M. Friess, as to whether the infection is due to something taken in with the breath or to ingestion of the water remains to be settled. The latter mode, however, is admitted to be very frequent, and as a cause of malarial infection the subject is by no means a new one, for many authors have not hesitated to condemn water as a vehicle of pathogenic agents. This, however, can not be proved absolutely; on the other hand, it is just as difficult to prove that the infection is due exclusively to air, because those who breathe this infected air also drink the water. Be that as it may, says M. Friess, malarial affections exist, and it is not to be doubted that the cisterns may be a medium of culture favorable to the development of malarial microorganisms. They are like malarial swamps in which the water becomes stagnant and changed, especially when the water is not deep enough, or when they are not subjected to a thorough cleansing.

The commonest form of fever in Jerusalem, says the author, is the intermittent, but there is another form which is continued, and it may at first be confounded with typhoid fever. The question as to whether this form of fever is purely of paludal origin can be answered only by microscopical examination, for in the Orient the religious laws absolutely forbid autopsies. The author says that he is convinced that this continued fever of Jerusalem belongs to the same class as the intermittent fevers, and that the cisterns are the cause of both forms of fever, for there is a great affinity between the two varieties. The patient attacked by one of these forms may find himself at a given time, in consequence of secondary reasons, under the predominating influence of the cause which engenders the other form, and in this way he passes from the intermittent form to the continued form, and *vice versa*. But the primitive pathogenic agent, says M. Friess, does not seem to be the same, and he is inclined to think that the continued fever of that country is due to a peculiar malarial poisoning.

This fever occurs at all times of the year, but especially during an epidemic of endemic affections. Age, sex, or individual conditions have no special action; those who are acclimated, as well as strangers, are attacked. Sometimes the duration is short, but ordinarily the affection is characterized by a long duration, by transformations, by the absence of complications which,

when they do exist, are of slight importance, by a hyperthermia which is often considerable, by a remarkable benignity, and by resistance to treatment with quinine. The duration can not be even approximately estimated, for in some cases at the end of five or eight days defervescence occurs suddenly or progressively. At other times the elevation of temperature continues for two, three, or four weeks, or even longer. The onset of the disease sometimes occurs suddenly with a severe chill; but, on the other hand, it may become prolonged from several neglected attacks of intermittent fever.

Defervescence often occurs suddenly, the temperature falling from 104° to 96.4° F. without critical symptoms; at other times it takes place gradually; again, after a more or less extended period of apyrexia, the temperature rises and veritable intermittent attacks are observed. The temperature ordinarily varies between 100.2° and 101°; occasionally temperatures of 104°, 105.4°, 107.3°, and even more have been observed. In one case the temperature, which was taken with different thermometers, rose to 109.2° without any complications. Cephalalgia was moderate, there was no dyspnea, the pulse was 120, and the general condition was not alarming. This temperature lasted for several hours, but it yielded easily to the employment of cold baths.

Complications are usually rare. Sometimes slight bronchitis and vomiting are observed. When the fever is high there may be some delirium, but under the influence of symptomatic treatment the fever is lowered and the delirium disappears. It is remarkable, says M. Friess, how, with such a high fever, the patient is in a comparatively satisfactory condition; there is no pain, cephalalgia is moderate and sometimes absent, and the appetite is good. The tongue is occasionally white and swollen, and the edges are not red; sometimes it is normal. Ordinarily there is constipation. Palpation of the abdominal organs does not provoke pain. There is no gurgling in the iliac fossa, and the dullness of the splenic region is not increased. Frequently the disease does not manifest itself except by a slight diminution in strength and by the prolonged elevation of temperature.

This fever, in the large majority of cases, terminates in recovery. Convalescence is of short duration, and relapses are not to be feared. It is astonishing, says M. Friess, to see how few traces there are of the disease after a patient has been in bed a month.

Large doses of quinine employed for a long time, in hypodermic injections or by the mouth, do not seem to have the least influence on the duration of the disease. The author has given as much as sixty grains of quinine sulphate in a day without obtaining satisfactory results; indeed, such quantities only provoke gastro-intestinal troubles and increase adynamia. Tonics and a methodical diet form the basis of the treatment. Hyperthermia is the principal symptom to be combated. M. Friess has given up the use of antipyrine, because it causes profuse sweating, which exhausts the patient, and in these cases it scarcely exerts any antipyretic action. Cold baths have given the best results. If, during convalescence, an attack of intermittent fever occurs, then quinine may be successfully employed.

**Rhachialgia of Hysterical Origin simulating Pott's Disease.**—In the July number of the *Annales de la polyclinique de Bordeaux* there is an account of a case which came under the observation of M. Gendron and M. Brunet. The patient was a child, nine years old, who suffered with pains in the spinal column. The family history was good, with the exception that a cousin

had Pott's disease in the dorso-lumbar region. The child had been reared under bad conditions; she had been badly nourished from birth and had been allowed to eat solid food at an early age. Her abdomen was swollen and there were undoubted signs of very pronounced rickets. She had never been subject to any of the diseases common to childhood, but for a year she had experienced pains in the spinal column, which were particularly pronounced in the dorso-lumbar region.

An examination was made and it was ascertained that pressure on the spinous processes at the level of the last two dorsal and of the first three lumbar vertebrae caused acute pain. Pressure was also painful over the right transverse processes of the corresponding vertebrae. On the left side nothing peculiar was observed. This exaggerated sensibility extended to the right of the vertebral column, independent of all definite nervous distribution, over a surface as large as one's hand. Pressure on the skin and on the superficial muscular masses only caused a sensation which was as acute as that caused by pressure on the bony apophyses. On the other hand, pressure on the top of the head did not give rise to any symptoms in the lumbar region. The movements of the lumbar column, extension, flexion, and lateral flexion were not at all restrained, and were produced without any stiffness. Under these conditions, the authors state, they were obliged to reject the diagnosis of Pott's disease, which at first had seemed the proper one.

Questioning the parents elicited the fact that the symptoms had shown themselves after violent emotion; that on one occasion, after an accident had happened to her father, an eruption had broken out over the child's body, but had disappeared in a few hours without treatment. Since then, analogous eruptions had occurred about every month. She was also subject to nightmare, became angry very easily, and cried profusely without any special reason.

The first pains in the spinal column were coincident with the first eruption; they were not ordinarily very acute, but the least shock, the least pressure on the spinal column would cause an exquisite pain. There was no trouble with the general sensibility; the pharyngeal reflex was completely abolished. Treatment was instituted which consisted principally in the employment of hydrotherapy.

The authors' conclusions are as follows: Undoubtedly hyperaesthesia in the region of the lumbar spine does not afford a sufficient reason to admit the existence of Pott's disease, especially when the other symptoms of the affection are entirely absent; but it is well, nevertheless, to be careful, for a superficial examination of a patient may lead to an error. An interesting point to be noted is the fact that the child's cousin suffered from Pott's disease and that the disease had developed simultaneously in both. The possible contagion of tuberculosis and the predisposition caused by common heredity are arguments which may be advanced in favor of the identity of the nature of the two affections. In this instance, however, it is doubtful, for in one case Pott's disease was evident, while in the other only the subjective symptoms were observed. Under these circumstances the question may be asked, whether it was not a case of simulation, or, rather, unconscious suggestion. The patient had the latent germs of a neurosis, which manifested themselves on the occasion of violent emotion, and the frequent reference to her cousin's health caused a vivid impression on her mind and gave rise to

an outbreak of painful symptoms which were identical in appearance only with those of Pott's disease.

**Kissing the Bible in Courts of Law.**—The *Australasian Medical Gazette* for June says: Dr. G. H. MacSwinney, of Stannmore, created no little sensation in the Sydney Divorce Court recently by refusing to kiss the Bible, when called upon to give evidence before Mr. Justice Simpson. He asked permission to make an affirmation instead of applying his lips to a book which had been kissed by all sorts and conditions of men and women.

His Honor: You object to kiss the book? What is your religion?

Dr. MacSwinney: I am Church of England. I do not object to take an oath, but I object to kiss the book.

Mr. Armstrong (the counsel who had called Dr. MacSwinney) suggested that witness should be allowed to take a "corporal oath," by holding the Bible in one hand and raising his other hand.

Dr. MacSwinney: That is always done at home when such an objection is raised.

His Honor: Never mind what is done at home. You don't object to take the oath? I suppose that if you had a nice new Bible you would not object to kiss that in the ordinary way?

Dr. MacSwinney: I would not.

His Honor: You only object to kiss a book which everybody may have kissed?

Dr. MacSwinney: Yes, your Honor.

Mr. Armstrong: I remember seeing a report of a Witnesses' Protection Society, which suggested that it would be a good thing if all witnesses objected to kiss the book.

His Honor: That might be a good thing from a medical point of view, but it would not be a good thing for getting on with the business.

Dr. MacSwinney: Nearly all the medical men in England object to kiss the Bible when being sworn.

His Honor: Never mind what the medical men in England do. *Medical men have a lot of fads.*

Dr. MacSwinney: This is no fad.

His Honor: The question is whether you can be allowed to make an affirmation when your objection to take an oath is not on conscientious grounds.

Mr. Armstrong urged that there were cases showing that a witness refusing to be sworn in the usual way could be sworn by holding the Bible in one hand and raising the other, or by making an affirmation.

Dr. MacSwinney, in reply to his Honor, said he had been about twelve years in the colony, and had probably given evidence twenty times before. He had always hitherto been sworn in the ordinary way.

His Honor: Then why have you taken this objection to-day?

Dr. MacSwinney: Because the question has been raised in medical circles at home, and it has been decided that witnesses may be sworn without kissing the book. I object to run the risk of getting any infectious disease. We know more about germs than we used to do.

His Honor: I wish you had taken this objection at some other time.

Dr. MacSwinney: I am sorry I have not done so before.

His Honor said that all evidence was *prima facie* given on oath, the witness being sworn by kissing the Gospel. Dr. MacSwinney could not be allowed to make an affirmation if he did not object on conscientious grounds to take an oath. The only objection the doctor

had was to kissing the book. The law only provided for persons who objected to take the oath from conscientious motives. A witness was sworn according to the ceremonies of his religion, as, for instance, a Chinaman was sworn by blowing out a match, breaking a plate, or in some other manner. Dr. MacSwinney belonged to the Church of England, in which the usual form of oath was by kissing the book. His Honor did not wish to decide off-hand an important point of this kind, but he would decide it, if pressed. He was not prepared at present to receive Dr. MacSwinney's evidence on affirmation. His Honor, in all his experience, had never known this point to be raised before. No doubt the point might be a good one on medical grounds.

Mr. Armstrong: Your Honor is aware this has been made a strong point among medical men in England.

His Honor: *Doctors talk a lot of nonsense.* They, of course, talk a lot of sense, too. If you want the evidence of Dr. MacSwinney, it would be worth while to send out and invest in a brand new Bible. Bibles are cheap enough, goodness knows! That would be the simplest way out of the difficulty.

A new Bible was sent for, and Dr. MacSwinney at once took the oath in the usual way.

Mr. Armstrong: I would like to press on your Honor that the doctor had a right to take a corporal oath.

His Honor: We can not take up time over that point now.

The case in hand was then proceeded with.

**To what Extent is a Pharmacist justified in Prescribing?**—This is the subject of an article by Mr. D. J. Thomas which is published in the August number of the *American Journal of Pharmacy*. The functions of the pharmacist, he says, are to compound and dispense physicians' prescriptions, and when he steps outside the realm of his vocation he transgresses the law regulating the practice of medicine. The medical law clearly defines the privileges of the physician, and in no part of the act does it extend to pharmacists the right to prescribe. It is an unwritten law, however, that under certain conditions pharmacists may exercise the functions of a physician very much as the wise old grandmother exercises this function when she says that catnip tea is good for babies. In cases of emergency—pending the arrival of a physician—a pharmacist may, from purely humane or philanthropic motives, prescribe and administer to the wants of a sufferer, and his rights in this instance may never be questioned. He sinks his identity and occupies the position of the good Samaritan.

The pharmacist does not possess the right to prescribe, simply because his knowledge of the physiological action of drugs is meagre and his power to diagnose disease is equally limited. His study and research are not along the same lines as those of the physician. He knows little or nothing of human anatomy, and very little more concerning the action of medicines upon the human system. He knows that acids sear and mucilaginous and oleaginous drugs mollify; but the mysteries of diagnosis place a barrier between him and the intelligent exhibition of the remedies he compounds with so much care, perfection, and accuracy. No pharmacist would trust his ability to such degree that he would exercise the functions of a physician to undertake the treatment of his own child afflicted with scarlet fever or any other serious disease. Why, therefore, should he usurp the right to play the rôle of physician in other cases? Is it because he has a lower estimate of a human life not

bound to him by the ties of relationship? The query is broad, inasmuch as it covers the moral and legal phases of the function of the pharmacist. Pharmacists should accord to physicians, without regard to its legal bearing, the privileges embodied in the Medical Act, and this carries with it nearly if not all the weight of the argument, viz., that pharmacists, *as such*, have no legal right and no qualification to prescribe, excepting, as previously stated, in such cases of emergency as demand immediate attention, and only pending the arrival of a physician; and in no event should they undertake the treatment of diseases, specific or otherwise, because they are fitted neither by education nor by moral or legal right to play the rôle of physician.

Mr. Thomas thinks there is a growing tendency on the part of pharmacists to recognize the rights of physicians, and that it is especially true since the enactment of the medical law. The pharmacists can not be accused, he says, of willfully trespassing upon the field of medicine prior to the passage of this act. They might be excused on the grounds that their jurisdiction was not clearly understood; but now the law clearly defines the offices of both pharmacist and physician.

It has been said, much to the discredit of the pharmacist, that he boldly and willfully exercises the function of a physician and defiantly disregards all ethical and legal laws that govern the two professions. However true this may be, it does not merit the condemnation of the medical fraternity upon all pharmacists. On the other hand, pharmacists should not condemn the entire medical profession for certain apparent irregularities committed by some who bring discredit and disgrace to their ranks. Pharmacists should, however, condemn and severely discountenance all transgressions of medical law by members of their profession. It has been intimated, but not fully authenticated, that in some instances pharmacists transgress the medical law to such an extent that they make gynecological examinations, and treat obstinate diseases of the eye, ear, nose, throat, urethra, and a score of other serious diseases that demand the attention of skilled physicians. These, however, are isolated cases, and very properly should be condemned.

In justice to the physician, and for the promoting of a more harmonious feeling between pharmacist and physician, says Mr. Thomas, the former should confine his attention to his own field of labor and not indulge in excursions into the field of the latter. The successful shoemaker sticks to his last, and it naturally follows that the pharmacist should stick to his pestle and mortar. Much of the criticism heaped upon the entire pharmaceutical profession is due to the reckless disregard of the rights of physicians by a few selfish and mercenary pharmacists. This self-sufficiency can not be too strongly condemned, and the members of the Pennsylvania Pharmaceutical Association should record their condemnation of such practice.

By closely observing the rights accorded to the physician under the act regulating the practice of medicine, much of the bitter feeling now existing between pharmacists and physicians will be dissipated and ultimately become a matter of history, and result in a warmer and more harmonious feeling between the two professions. Physicians are much criticised for their action in the matter of dispensing their own medicines. They defend their action by alleging that they have been forced into it by a custom established by the homeopaths, who universally dispense their own medicines. Some physicians state they have been obliged to do so by the phar-

macist who "counter-prescribes." This is one of the parasitic evils that cling to the profession.

Mr. Thomas recommends pharmacists to meet the physician more than half way, and thinks that by denouncing all transgressions of the latter's rights they will eventually establish themselves in the admiration of the medical fraternity, and give to pharmacy a higher position in their estimation.

**Latent Ulcer of the Stomach.**—The *Presse médicale* for July 25th contains the following account of a remarkable case of latent ulcer of the stomach, which came under M. Dieulafoy's observation: The first symptom which manifested itself was perforation; there had been no previous gastric symptoms, no dyspeptic troubles, and no vomiting of blood. The patient was a young woman who was apparently in good health, although about two months before she had complained of pain in the stomach, to which, however, she did not attach much importance. Her appetite was good, and she never complained of indigestion, and on the day that perforation took place she performed her usual work and appeared to be perfectly well. Shortly after dinner she was suddenly seized with a horrible pain in the epigastric region, and a physician was called. But he could not make an exact diagnosis, and, thinking that it might be a case of hysteria, prescribed for the patient an enema containing laudanum. On the following day M. Dieulafoy saw the patient. The pain was then somewhat mitigated, but it extended over the entire abdomen; the abdominal wall was tense rather than swollen, and the slightest touch or pressure over the abdomen was intolerable. The pulse was frequent, but the general condition was rather good; the expression of the face was not anxious, there were no peritoneal facies, no hicough, and no vomiting. However, M. Dieulafoy gave a diagnosis of generalized peritonitis, and the patient was immediately taken to the hospital, where an operation was performed. At the time of her admission the temperature was 101.6° F., and the pulse 120. The abdomen was swollen and tense. Median subumbilical laparotomy was practised, and when the abdomen was opened a stream of yellowish liquid escaped. The intestines appeared to be congested, and their surface presented creamylike false membranes of recent formation. The appendix was found to be in a healthy condition, and the genital organs were not involved; the seat of the peritoneal lesion was evidently the upper part of the abdomen. During the exploration the patient's general condition became so aggravated that it was not thought prudent to lengthen the incision and prolong the operation, so the abdomen was closed after the peritonæum had been subjected to lavage with boiled water. The patient died on the following morning.

At the autopsy the integrity of the appendix and the genital organs was verified, but on the anterior surface of the stomach, at a distance of about a centimetre from the small curvature, and at an equal distance from the cardia and the pylorus, a large perforation was found; it was of about the size of a fifty-cent piece, and its borders were not thick; there were no surrounding peritoneal changes. On the posterior surface of the stomach there were some adhesions which united it with the pancreas; these adhesions were very loose, and were easily torn away by the finger. They surrounded a second perforation, which corresponded exactly in size, shape, and situation with the first one. The appearance of these ulcers resembled the classic type of simple ulcer

of the stomach, and they had certainly existed a long time before perforation occurred.

It is incomprehensible, says M. Dieulafoy, how an ulcer which was serious enough to cause perforation could have remained completely indolent; it is possible, he thinks, that symptoms had manifested themselves at some time, and that they had been forgotten by the patient or neglected by those who observed them. M. Dieulafoy thinks that this case demonstrates that, in the presence of a sudden attack of peritonitis, the physician should not attribute it only to appendicitis, salpingitis, intestinal perforation, or perforations of the biliary tracts, but to perforations of the stomach as well, although there may be no history of previous gastric troubles. At the present time, he says, when surgical intervention in peritonitis is of daily occurrence, an early and correct diagnosis may, in favorable cases, assure the recovery of the patient.

**Eucaine as a Local Anæsthetic.**—In the *Lancet* for July 11th Mr. Robert Brudenell Carter, consulting ophthalmic surgeon to St. George's Hospital, London, remarks that Dr. G. Vinci, of Messina, described eucaine as possessing the properties of cocaine as a local anæsthetic, but as being less toxic and as having no effect upon the pupil. The last statement seemed to Mr. Carter to be of practical importance, because a dilated pupil is an impediment to the performance of many operations upon the eye. It has long been his practice, he says, to neutralize the dilating effect of cocaine by a preliminary application of eserine, but this course is not entirely satisfactory. It is difficult to secure the precise degree of effect desired, while the eserine dilates the vessels of the iris and occasions free bleeding when they are incised. It also renders the iris tissue comparatively rigid, so that it is less easily drawn out of the anterior chamber. Mr. Carter obtained a supply of a five-per-cent. watery solution of eucaine hydrochloride, and used it for a cataract extraction. Before his arrival the nurse had applied a drop of the solution within the lower lid every five minutes for six times, and he found the eye perfectly insensitive. The pupil was unaffected and acted readily to light. There was scarcely any bleeding from the cut iris, there was perfect quiescence of the muscles, and there was no pain. He asked the patient whether she had felt anything, and she replied: "I felt something moving about my eye, but it did not hurt me." There was no pain afterward and healing was uninterrupted. He has since successfully used a single application of the same solution as a preliminary to the removal of a foreign body imbedded in the cornea.

In the original paper, it is said that eucaine has been successfully used in dentistry and laryngology, and that solutions may be injected hypodermically without injury. Mr. Carter says that his first experiments will certainly induce him to use it again, and for tenotomies as well as for iridectomy or extraction. It is said, he adds, that the solution above mentioned may be sterilized by boiling again and again, if necessary, without undergoing decomposition or suffering any deterioration of quality.

**The Business Aspect of Medical Practice.**—Dr. J. C. Bennett, of Yonkers, writes to us as follows, under the heading of Mistakes of the Profession:

"Six years ago, when I began the practice of medicine, there were many things that elicited my amazement, principal among which were the methods pursued by doctors generally in the conduct of their business.

I do not suppose I should speak of such conduct as methodical, for it has never reached the dignity of a method. I observed that doctors were exceedingly lax and irregular in attending to the financial side of their practice, and this was all the more a source of wonderment as I saw everywhere, in all lines of business, men conducting their affairs in a most thoroughly systematic manner. And, strange at it may seem, this condition of things has always existed in the medical profession. For years it has been the custom to send out bills but once a year, and such a thing as suing for a claim was almost unheard of, except in the rarest and most aggravated instances. Now, some have broken away from that time-honored custom, and send out their bills twice a year. Thirty days, I believe, is the time limit of credit in the business world—here it exists without a limit. Such a practice is fraught with the most disastrous consequences to a physician's finances, as it teaches the people to defer payment almost indefinitely, especially where there are other claims that are being pressed.

"As an illustration of the negligent manner in which the average physician collects his bills, the following is a fair example: The other day a man told me he had been asking and reasking his physician for more than a year to send him a statement of his account, but, notwithstanding it was nearly of two years' standing, he had been unable to get one. Such conduct would eventually kill any business. The conclusion that the people naturally come to is that a doctor either is very fond of work or values his services very lightly, otherwise he would insist upon payment, as all other men do. The above-named gentleman is engaged in business in this city and, consistently with business methods, recognized and followed by all business men, he sends out his bills every month; should payment not follow after two or three months, he does not hesitate to adopt measures to collect. Such is business, and all men expect it. Why do doctors disappoint them? I am sure, had the doctor who had neglected to send his bill as requested gone into that gentleman's store and made a purchase for which he did not pay, he would beyond the shadow of a doubt have received a bill for the same, at least by the end of the month.

"Some years ago a doctor told me he had twenty thousand dollars on his books that he never expected to get. He practises in a small town, and that twenty thousand, which had accumulated in about fifteen years, represented a vast amount of work—many weary days and sleepless nights. While he charges a dollar and a half a visit, he said he would willingly accept fifty cents, if that fifty cents was paid at each call. How many doctors would willingly do the same, for surely a dollar in the hand is worth two on the books! It is a decided relief to find now and then a doctor who has some business method about him, who conducts his business according to business principles, who sends out his bills regularly each month, who gives people to understand that they can not use him, and that they must pay for what they get. But where you will find one such, you will find ninety and nine who are easy victims for every Tom, Dick, and Harry who happen to need their services. A perfect stranger calls on a doctor, receives his advice and sometimes his medicine, and walks out without paying a cent. Has this any counterpart or parallel in any other department of human affairs? If so, I have never seen or heard of it. It is surprising, the amount of work doctors do for which they never receive the slightest remuneration. No other class gives so much

and receives so little. Night after night they allow themselves to be called out to go to some distant point without a murmur and in many cases without a dollar. They will expose themselves to all kinds of weather and face the worst and most malignant diseases without a certainty, and often without a possibility, of ever being paid. And 'the most unkindest out of all' is that these very people, as a sort of justification for not paying, will cruelly criticise the services and do all they can to injure the doctor's reputation. This is their only pay—the pay of ingratitude. It is therefore positively dangerous to work for people who do not and will not pay, and the sooner a doctor realizes that fact and acts accordingly, the better for him. But in the medical profession it seems that experience does not teach, and the evil still continues.

"It is truly amusing, to say the least, to see doctors scrambling to do service for a city or State, as though it were the most exalted privilege or highest honor to do so, while all other men value such honor or privilege only as it is accompanied with a good price. And why a doctor should under any circumstance, any more than any other man, render his services for nothing is something that passes my understanding. The city or State is fully able to pay for its work; still I do not blame them for allowing men to work for them gratuitously, if they are so very desirous and do it well. During all our epidemics of small-pox, diphtheria, cholera, etc., the physicians have been the instruments of their extermination. They have proffered their services to the city, State, or nation, as the case may be, and in the vast majority of instances have asked nothing in return. How often in this city during the past five years have I seen the doctors give their time and advice, unasked and unsought, for the betterment of the public health! It is right and proper that they should be the promoters of health, public as well as private, for they are the ones best qualified for such work, but it is only fair and reasonable that they be paid for what they do. During the recent epidemic of cholera, the physicians did for nothing what would have cost the country millions had the work been done by any other class of men; and had this work not been done, it would surely have resulted in closing the World's Fair, to say nothing of thousands of lives that would have fallen victims of its awful ravage. Can you find a lawyer who will test the constitutionality of a law for the glory there is in it? I think not. They have always been such guardians of their interests that the people expect to pay them a big fee even for the slightest service. Doctors, on the other hand, have been so lavish and prodigal of their services and work that it has naturally given rise to the impression that their services can be had merely for the asking. In this city the salary of the city judge is more than twice as large as the health officer's, and yet the duties of the former are as nothing compared with the latter's. The health officer has, among other things, to attend to the sanitary condition of the city—no small thing, I assure you—and to go when called, either day or night, to the sick poor. In fact, so much of his time is consumed in attending to the various requirements of the city that his private practice suffers an irreparable loss. As I have said, in comparison the city judge's work is very slight, and rather than the office injuring his private business, it is a decided advantage in increasing it. Again, take the case of the health officer of New York city, and you will find that almost any of the clerkships of the various commissions pay more. And where is there a physician who

in the service of a city, State, or nation receives anywhere near the amount paid a Supreme Court judge? And yet doctors are, as a rule, better educated than lawyers. Every one will naturally ask why they do this. But that is the riddle of the sphinx. Surely it is not because they are the recipients of so many public favors. Why, neither the State nor the county will grant a doctor a license which will permit him to do so much for them for nothing, unless he pays a fee for it. Everywhere and for everything they are obliged to pay. When will they rise in their might and demand of the public a just recognition of their services?

"There are a few other errors to which I would briefly refer. There is a mistake which doctors for years have made and are still making, and concerning which many of the best and most learned men of the profession have written and spoken in complaint. I refer to that ubiquitous evil—the dispensary. Everywhere is to be found the dispensary. Thousands every day repair to these places for advice and treatment because there is nothing to pay—thousands who are fully able to pay for all they receive. People of wealth even patronize these institutions. Every doctor knows this, and still the evil goes on, ever on the increase, and the doctors again are the losers. But this is an evil that must be borne till all the doctors with one accord unite against it. The young doctor feels constrained to give his time and attention to this sort of work, because others do it, and, as he imagines he would be decidedly handicapped by rebelling, reluctantly submits. With him it surely is no charity, but a means to an end. There are many men to-day masquerading before the public as philanthropists and benefactors of mankind whose claims to such a title are very doubtful indeed. A rich man builds a hospital, endows it with a certain sum of money, and then takes advantage of the mistake which physicians have made to receive their services free of charge, and the rich man gets all the glory. Is that truly philanthropic? If so, surely there is something higher and nobler than philanthropy.

"Just one other thing I desire to speak of, one which has always been a source of wonder to every one outside of the medical profession—I mean physicians' false system of ethics. I say false because it embodies many grave and vital errors—some of which have forced many men of good standing out of the ranks of professional recognition and compelled them to conduct their business in the only way whereby they could receive an introduction to the public. The profession has surely suffered by its intolerance of sound business principles. There is only one error, however, which I will specifically mention—one which imposes a restriction that is contrary to one of the most important principles of freedom, namely, the right of every man to the fruits of his own industry. This restriction forbids a doctor keeping secret, or for his own use, any medical fact, though the discovery of that fact has cost him years of patient toil and the outlay of considerable money. He has no alternative but to make known every detail of his discovery without compensation or reward. Surely there is no justice in that. A man, no matter if he is a doctor, has a right to profit by what his genius or his hard work has succeeded in finding out for him. While he has been plodding away for years over some experiment, the rest of the profession has been profiting materially by their practice. So why should not he by his discovery? If the profession wants it, let them pay for it, or if it is of great value to the public generally, let the State or nation

buy it. A system of ethics that would embody any such principle or impose any such obligation would be considered fanatical outside the medical profession.

"I have written this article, crude as it may be, at the special request of many members of the fraternity, in the hope that it may be the beginning of a movement to institute a reform which will prove an inestimable blessing to every member of the medical profession and gain for it that respect to which it is so justly entitled."

**Hot and Cold Applications in the Treatment of the Eye.**—In an article on this subject in the August number of the *University Medical Magazine* Dr. William C. Posey, of Philadelphia, remarks that it is evident that heat and cold exert a profound influence upon the temperature of the human eye, and that the intensity of their effect depends largely upon the length of time they are applied. If, therefore, the treatment of ocular diseases was simply a question of influencing the temperature, the indications for the employment of these agents would be quite simple, but in addition to the action which they have upon heat control, that which they exercise upon the circulation of the eye, independent of its influence over the regulation of the amount of heat in a part, is of no less significance from a clinical standpoint.

In inflammatory conditions, cold limits the exudation and checks the secretion by constricting the capillaries, while heat aids in the healthful repair of tissues by promoting absorption of the exudation and by carrying the proper nourishment to the part.

Again, in the early stages of inflammation, cold relieves pain both by preventing the flow of blood to the part by its contracting the blood-vessels and by its limiting the amount of exudation. In the latter stages heat relieves pain by causing absorption of the exudation and lessening the tension of the inflamed area. Moreover, heat greatly augments the diffusibility of liquids into the eye, for Kellarmoff and Dolganoff have shown that the rapidity and the amount in which drugs are absorbed after the application of the hot compress are due to a change which is wrought in the corneal epithelium.

Finally, both agents have a germicidal action. It has been found that a 1-to-10,000 hot solution of bi-chloride of mercury is more efficacious in preventing pus-formation than a cold one of 1 to 2,000. Water itself at a temperature of from 230° to 284° F. kills many bacteria, while cold, even of the degree at which it may be applied to the eye, will hinder the development of germs and prevent their growth.

Heat and cold may be applied in either a moist or a dry form. A greater action is usually derived from the moist compress, whether it is hot or cold, for Jaenec, says the author, has proved that therapeutically moist heat is not only more penetrating than dry heat, but gives a greater variation in the degree of heat. Giesse has also shown that the cold compress will lower the temperature much more rapidly than bladders filled with ice; moist applications also possess the greater advantage of washing away all secretions from the conjunctival sac.

In regard to the toilet of the eye, lukewarm applications will be found to give the greatest comfort to the greatest number. A little boric acid or sodium chloride may be added to the water and make the application even more grateful. In regard to the practice of opening the eyes in a basin of water after the head has been

immersed in it, says Dr. Posey, we are not fishes; our eyes are not adapted for such a procedure, and we should rest satisfied with the glass dropper or the eye cup.

In hyperemia of the conjunctiva, induced by ametropia or by the presence of a foreign body, cold is a simple but effective means of restoring the membrane to its healthy condition. In these cases, the douche or the compress may be applied over the closed lids with the greatest advantage for fifteen minutes at a time. The water employed should not be too cold, or excessive reaction may follow its use.

In the severer forms of conjunctivitis, when there is a purulent inflammation or an exudate, ice is the sovereign remedy, and there is but one way to apply it, by the continued use of the ice compress. Disastrous results need not be feared, says Dr. Posey, from its prolonged application, for of all the remedies used to combat this type of disease in the early stages, this is undoubtedly the best. At the outset of the disease the board-like swelling of the lids is doubtless one of the chief causes in elevating the temperature, and, as the swelling and induration prevent the cold from gaining access to the eye, it is necessary that the treatment should be energetic and prolonged. The application of compresses, therefore, should be maintained night and day in such cases, and should only be desisted from when a corneal ulcer threatens or the secretion becomes excessive. If either of these two contingencies should arise, the ice compress should be replaced at once by the hot application, and this should be persisted in for fifteen minutes every two or three hours. The hot water will relieve the stagnant condition of the corneal circulation that has been induced by the intense chemosis of the bulbar conjunctiva, and thus favor the repair of the cornea.

In treating disease of the cornea hot compresses are always indicated, never cold. The cornea is normally a non-vascular structure, and is dependent for its nourishment upon the tissues surrounding it, and if these are diseased, a stasis in the nutritive supply of the membrane occurs, and ulceration ensues. The chief indication, therefore, in treating diseases of the cornea is to prevent this stasis. This, he says, is admirably accomplished by means of moist heat, provided it is properly applied. One of the most frequent forms of corneal ulceration is phlyctenular keratitis. This disease occurs usually in children of a scrofulous diathesis, and there is no sadder sight and more striking example of the injury which is wrought by the ignorant application of remedies by the laity than is seen in this disorder. The author states that it is frequent in the ophthalmic clinics to hear the mothers of such children recite with pride a list of all kinds of harmful and disgusting substances with which they have poulticed the eye—tea leaves, rotten apples, raw oysters, bread and milk, and potatoes are the favorite articles, and the persistency and the ignorance with which they are employed are most distressing to the intelligent practitioner, and he says emphatically that poultices should never be employed in diseases of the globe itself, although they are at times of service in inflammations of the amnixa.

Instead of the use of the poultice, moist heat is best applied in diseases of the cornea by the ordinary compress, which should be kept applied for ten or fifteen minutes at a time four or five times daily.

Hot compresses will be found to be an excellent stimulant to sluggish ulcers, and will also hasten the absorption of nebulae. A few drops of scalding water,

applied directly to a mycotic ulcer, will exert a powerful antiseptic action upon it. In interstitial inflammation of the cornea also, when the whole uveal tract is inflamed, and the ciliary body especially is hyperemic, much relief will be afforded by the prolonged and unvarying use of hot fomentations, for from three to eight hours daily at periods of every two hours. Indeed, where posterior synechia have not yielded to atropine, and where there is a rise in the intraocular tension, the mydriatic will have to be withdrawn, and only hot applications and the administration of an alternative internally to lessen the inflammatory condition can be used.

In the early stages of granular conjunctivitis hot water is frequently badly borne; as soon as the vascular condition of the cornea manifests itself, however, the use of hot compresses should be inaugurated, for the inflammatory reaction which they occasion is frequently sufficient to cause the disappearance of the pannus.

One of the most distressing symptoms of phlyctenular disease, continues Dr. Posey, is the photophobia with spasm of the orbicularis which it occasions, and great difficulty is often encountered in applying the proper remedies to the eyes until these have been made to subside. In urgent cases the eyes may sometimes be opened by immersing the entire head of the child in a bucket of cold water, the sense of suffocation and shock causing it to open its lids in a reflex way as it gasps for breath. An equally effective and less heroic measure consists in permitting a few drops of ice water to trickle between the lids, which are gently coaxed apart by the surgeon's fingers.

It is a matter of experience that dry heat is more efficacious than moist heat in soothing the pain of neuralgia. It will also be found that in cases of iritis, when there is little or no secretion except the tears of reflex irritation, the dry compress is the most efficacious, while in iritis secondary to inflammations of the cornea the moist compress gives the best results.

In addition to its action upon the blood-vessels of the iris and ciliary body, the hot compress is invaluable on account of its increasing the absorption of drugs which are used for the purpose of dilating the pupil. It will frequently be found that mydriatics exert but little influence over the pupil in cases of iritis, even when the synechia are not very tenacious. Leeching and cocaine will partly overcome this, but there is nothing so efficacious as bathing the eye with water as hot as can be borne about ten minutes before the instillation of the mydriatic.

After penetrating wounds of the eye, particularly when the iris and the lens have been injured, and if there is the complication of plastic iris and traumatic cataract, in addition to the other treatment, the author states that the continuous use of the ice compress will be found to be a potent agent in combating inflammatory reaction and in preventing the invasion of noxious germs by reducing the temperature of the parts. In suppurative panophthalmitis, he says, hot applications are grateful from the very onset and may be kept up almost continuously. The pain arising from muscular asthenopia is also often allayed and the symptoms at times are made to disappear by the use of hot compresses, for the heat actually increases the contractile power of the weak muscles. But if there is any tendency to disease of the deeper structures of the eye, such as the retina or the optic disc, it is well to avoid the use of hot applications, as they may cause further mischief by increasing congestion in these delicate membranes.

## Lectures and Addresses.

### LECTURES ON ANGINA PECTORIS AND ALLIED STATES.\*

By WILLIAM OSLER, M.D.,

PROFESSOR OF MEDICINE, JOHNS HOPKINS UNIVERSITY, BALTIMORE.

#### LECTURE II.—ANGINA PECTORIS VERA.

ETIOLOGY.—GENERAL DESCRIPTION.

INCIDENCE OF THE DISEASE.—As noted long ago by Sir Gilbert Blaine, angina pectoris is a rare affection in hospital practice. Gairdner criticises this statement rather sharply, and yet I think that a majority of hospital physicians would be found to support it. During the ten years in which I lived in Montreal, I did not see a case of the disease either in private practice or at the Montreal General Hospital. At Blockley (Philadelphia Hospital), too, it was an exceedingly rare affection. I do not remember to have had a case under my personal care. There were two cases in my service at the University Hospital. During the seven years in which the Johns Hopkins Hospital has been opened, with an unusually large "material" in diseases of the heart and arteries, and with many cases of heart pain of various sorts, there have been only four instances of angina pectoris. You will find the statement in Fagge's *Practice* (third edition, vol. ii, p. 26) that "the writer has never seen classical angina in hospital practice."

On the other hand, an individual consultant may see within a year more cases than occur in all the hospitals of his town within the same period. In corroboration of this striking contrast between the incidence of angina pectoris in hospital and consulting work I may refer to the statistics of the Edinburgh Royal Infirmary, in which for the two years covered by the *Hospital Reports*, 1893 and 1894, there were five cases among a total of 8,868 medical cases. Compare with this the personal experience of the distinguished Edinburgh consultant, Dr. Balfour, who, in his recently issued work on *The Senile Heart*, gives an analysis of ninety-eight cases of angina pectoris seen within ten years. My individual experience embraces a series of sixty cases, forty of which may be regarded as true angina.

The predisposing causes of angina pectoris vera are those of arterio-sclerosis; that is to say, so intimately associated is the true paroxysm with sclerotic conditions of the coronary arteries that it is extremely rare apart from them. Men of muscular, even athletic build, who have been *dévotés* of Bacchus and of Venus, form perhaps the largest contingent. Gout, syphilis, and heredity influence the causation only so far as they tend to cause sclerotic changes in the arteries; but it would be altogether too narrow a view to suppose that the ætiology of the disease is identical with that of arterio-sclerosis.

The one is so common and the other comparatively rare, even among the individuals most prone to sclerosis, that there must be a third element, an indefinite something, which yet escapes our knowledge, but which is the essential factor in the production of this terrible affliction.

STATION IN LIFE.—As Sir John Forbes remarks, it is an attendant rather of ease and luxury than of temperance and labor; on which account, though occurring among the poor, it is more frequently met with among the rich, or in persons of easy circumstances. It is remarkable how many prominent individuals have succumbed to the disease. We may say of it as Sydenham did of the gout, that more wise men than fools are its victims.

I do not know that any special occupation or profession predisposes to it, but the frequency with which physicians are attacked has been commented upon by several writers. In my list of sixty cases of all forms, there were thirteen medical men, eight of whom had true angina. This percentage is doubtless exceptional, and due, in part at least, to my nomadic habits, and wide acquaintance in the profession.

SEX.—From the earliest description of the disease, the remarkable preponderance of males who are attacked has been noted. Heberden says: "I have seen nearly one hundred people under this disorder, of which number there have been three women" (*Commentaries*). The statistics collected by Huchard give in two hundred and thirty-seven cases of true angina only forty-two in women. In my own series of forty cases of true angina there was only one woman.

AGE.—The age at which it is most common is that of arterio-sclerosis—after the fiftieth year of life. Of the forty cases on my list there were only four under the fortieth year. One of these, a man, aged thirty years, had had syphilis five years before; the other case, a woman, aged thirty-two years, had mitral-valve disease; the third case had terrible attacks of angina following chronic pleurisy. In the fifth decade there were thirteen; in the sixth, thirteen; in the seventh, nine; and of one case I did not get the exact age. The average of the thirty-nine cases was about fifty-three years. Cases are reported in quite young individuals, even in children, but such are almost invariably the subject of chronic valvular disease or adherent pericardium.

EPIDEMIC, IMITATIVE, AND EMOTIONAL INFLUENCES.—Laennec was "of the opinion that the prevalent type of disease influences its development," and adds, "I have some years met with it frequently, and hardly at all in others." You will find reference in the literature to so-called outbreaks of angina which have been reported by Kleefeld\* and by Gelineau.† I can not see that the cases recorded by Kleefeld have anything to do with

\* Delivered to the Post-graduate class, Johns Hopkins Hospital.

\* *Journal d. pract. Heilkunde*, 1823, lvi.

† *Gazette des hôpitaux*, 1862, xxxv

angina pectoris. He describes the epidemic as a remittent fever with gastric complications, and much pain about the heart. Some of the cases were fatal, but no autopsies were made. Young persons, chiefly women and children, were attacked.

Gelineau, surgeon to the French corvette *L'Embucade*, reports a remarkable outbreak among the sailors during a prolonged cruise in the Pacific. Scurvy had broken out and the men were much debilitated and anæmic. They became subject also to a severe dry colic. Following this there were many cases of angina. The first case was that of an old sailor, scorbutic and anæmic, who while climbing the mast was seized with intense pain about the heart. Five days after, five other men were attacked in the same sudden way, and three days later, three more. Gelineau lays a good deal of stress upon tobacco as a factor in the causation of the pain, and also upon the debility following the scurvy, dysentery, and dry colic. The effect of imitation, that extraordinary occult influence so potent in many forms of hysteria, must, no doubt, be taken into account. Perhaps the most notable instance is given by Dr. Taber Johnson in his report of Mr. Sumner's case.\* "I have observed a curious fact, which it may be interesting to refer to here. I mean the unusual number of patients suffering from this disease, who, previous to Mr. Sumner's severe illness, had never supposed that they had any disease of the heart. This fact has been referred to by newspaper correspondents—viz., that during the illness of Mr. Sumner, and especially since his death, instances of its occurrence have considerably increased, and especially among those who strongly sympathized with the late senator. This seemingly sympathetic cause of disease has been noticed in other cases. I have been consulted by as many as thirty individuals, since Mr. Sumner's death, who imagined they were afflicted with his complaint. In some of these cases there was organic disease of the heart, but in a majority of them there was no cardiac trouble at all. Two weeks after the autopsy in Mr. Sumner's case, one of the physicians who assisted, a devotedly attached friend of the deceased, died of angina pectoris. I am informed that Dr. Hitchcock had but a few attacks, and that, prior to Mr. Sumner's death, he had never been a sufferer from angina pectoris."

Dr. Johnson says that he himself suffered from two attacks very closely resembling, if they were not really, angina. One of these occurred immediately after Mr. Sumner's death, and Brown-Sequard, who was present, said the phenomena were undoubtedly those of a paroxysm of angina. Twenty-two years have passed, and, happily for himself, as well as for our brethren of the District of Columbia, Dr. Taber Johnson has now less mobile nerves.

In Case X of my series of pseudo-angina the patient's husband died suddenly in a paroxysm of true angina.

Mental worry, severe grief, or a sudden shock may

precede directly the onset of the attacks. In Case XXXVI, the paroxysms came on after the shock of the announcement that a son had committed suicide.

HEREDITY.—True angina pectoris is an arterial incident, and, as we know that the members of certain families show a special tendency to arterial degeneration, it is not surprising to find cases in father and son, or in brothers, or even in representatives of three generations. There are remarkable instances on record in which many members of a family have been attacked. The first, and one of the most notable, is that reported by Dr. Robert Hamilton,\* in which the father of the patient, a young man aged twenty-four, two brothers, and one sister were affected. In all, the disease developed in early life; in Hamilton's own patient, at the twelfth year. It is quite possible from his description that the disease may not have been angina pectoris, but spasmodic asthma associated with heart pain.

The best-known instance is that of the Arnold family. William Arnold, collector of customs of Cowes, died suddenly of spasm of the heart in 1801. His son, the celebrated Thomas Arnold, of Rugby, whose case I will narrate to you shortly, died in his first attack. Matthew Arnold, his distinguished son, was a victim of the disease for several years, and died suddenly in an attack on Sunday, April 15, 1888, having been spared, as he hopes in his little poem called *A Wish*—

"The whispering, crowded room,  
The friends who come, and gape, and go;  
The ceremonious air of gloom—  
All, which makes death a hideous show!"

At the time of his death, the accounts which appeared in the *Lancet* and *British Medical Journal* were not clear as to the existence of attacks of angina. The various stages in the progress of his illness can be traced very well in his *Familiar Letters*,† in which you will find an account of numerous attacks from May, 1885, until the time of his death.

In looking over the literature one finds occasional references to cases occurring in several members of one family. Cazanave de la Roche‡ records three cases in one family—a sister, who was affected at the time of the report, and two brothers who had died of the disease. In Case XXIII on my list the patient's father died of angina pectoris.

GOUT.—The relation of certain constitutional disorders to angina pectoris has been much discussed. The importance of gout as a factor was early suggested, and in this interesting little monograph of Butter's, which I show you here—the first separate treatise on the disease—the author places the seat of the disorder in the diaphragm, and calls it diaphragmatic gout. The affection has also been termed asthma arthriticum.

Nathaniel Chapman advocated strongly the arthritis

nature of angina pectoris, and there can be no question, I think, that in a certain number of the victims gout plays an important rôle in inducing the arterio-sclerosis.

I have been particularly interested in examining into this point in the cases which have come under my observation within the past four or five years. There are four cases at least of my series in which gout seemed to play a part. Dr. —, of Virginia, seen April 3, 1894, a very robust, vigorous man of forty-eight, temperate, a hard worker, who had not had syphilis, and in whom the attacks were fairly characteristic, thinks that gout (which is in his family) is directly responsible for the attacks. Certainly, after using without benefit for many months the iodides and the nitrites, he obtained the greatest relief from a prolonged course of colchicum. It is now more than two years since I saw him, and he remains well. In another case, a patient with attacks of angina pectoris *sine dolore*, there had been attacks of acute articular gout. In a third case, a man aged sixty-four, the upper half of the pinna of the lobe of the right ear was firm and calcified, and the same process was beginning in the left ear. There were no topi, but the calcification was, to say the least, suggestive. A fourth case was that of a physician from North Carolina, aged forty-six, who had for many years attacks of gouty arthritis, chiefly in the big toe, less frequently in the ankles. There was a well-marked tophus in the right ear.

**DIABETES.**—The association of angina pectoris with diabetes has been frequently noted. No instance has fallen under my personal observation. You will find the whole subject very thoroughly discussed by Ebstein in a recent paper in the *Berliner klinische Wochenschrift* of last year (1895).

**SYPHILIS** is one of the potent factors in inducing arterio-sclerosis, and thus indirectly plays a rôle in angina pectoris. Of the cases in my series, only four gave a history of syphilis. The instances of aortitis to which I have already referred, occurring in the third and fourth decades in men who have had syphilis, have worked hard, and have been heavy drinkers, are sometimes associated with severe attacks of angina. In Case I, Lieutenant X., aged thirty years, a robust, powerful man, had had syphilis six years before his visit to me. The secondary symptoms were slight, and he had not had very thorough treatment. A year before I saw him he began to have severe pains in the heart, recurring in paroxysms, and associated with pain down the left arm, and dyspnoea on exertion. There was no perceptible enlargement of the heart; there was a systolic murmur at the apex and a soft bruit at the aortic area, without special accentuation of the aortic second sound. The attacks had been of such severity that he had been off duty for many months. He improved very much upon the iodide of potassium, but still had attacks six months after I saw him, since which time I have not heard of him. Corri-

gan's case, you remember, the illustrative plate of which I showed you at the last lecture, was in a young man, and belonged to this group. The frontispiece in Balfour's work on the heart (second edition) illustrates another case of the same kind in a still younger man, aged twenty-four years. The angina attacks were associated with an aortitis which narrowed greatly the orifices of the coronary arteries.

**SPECIFIC FEVERS.**—In connection with the specific fevers several writers have described anginalike attacks. Fraentzel, in his *Vorlesungen über die Krankheiten des Herzens* (Berlin, 1889), describes attacks of angina pectoris in the weakened and dilated heart following the infections, particularly erysipelas, typhoid fever, and pneumonia. J. W. Moore\* has reported two instances of anginal symptoms in connection with heart weakness during and after the specific fevers. In the epidemic of a remittent fever reported by Kleefeld (and already referred to) the attacks of heart pain may have been of this character. I do not remember to have seen a case in which the attack developed during convalescence from one of the ordinary fevers.

Among the many nervous sequelæ of *influenza*, few are more distressing than the attacks of severe cardiac pain. In some cases, indeed, the disease seems to have been the starting point of attacks of true angina. The frequency of the complication in the practices of some physicians is remarkable. In a paper on *The Action of Influenza Poison on the Heart*, Curtin and Watson state that within two years they met with fully seventy cases of painful attacks about the heart. The illustrative cases in their paper † show that some of the attacks must have been of very great severity, but, in most instances, the duration of the disease was short and the cases evidently belonged to the category of pseudo-angina. I have seen but two instances in which the attack seemed to follow directly upon the influenza. One is certainly pseudo-angina; the other proved to be the genuine disease.

I saw on several occasions in Toronto a medical friend who, after a tolerably severe attack of influenza about three years ago, began to have attacks of agonizing pain about the heart. They came on without warning, the pain appearing in various parts of the chest, commonly under both shoulder blades, and especially severe in both wrists. There was at first no irregularity of the pulse or difficulty in breathing; but in some attacks there were piping râles during expiration. At first these attacks were almost nightly; several times they ended in vomiting (preceded by profuse salivation) the passage of more or less flatus, and copious sweating. There was no mental anxiety whatever, except, as he expressed it, "the pain was so intense that I was afraid I would recover, in order to endure it again." The pain in the arms was chiefly in the front of the wrists. The patient had not had any serious illness previously, had never had syphilis, had not been a heavy drinker, but had been a

\* *Dublin Medical Journal*, 1890, vol. lxxxix.

† *International Medical Magazine*, January, 1895.

pretty heavy smoker. The attacks recurred with intensity throughout the early part of January. When I saw him there were no signs of cardiac disease. He had had a good deal of digestive disturbance. During the following summer and autumn he progressively improved, and I heard from him recently to the effect that now only in any extra strain, as in the attendance upon a difficult case of labor, does he feel any pain. He used the iodide steadily for some time without any special benefit. He attributes more benefit to lavage of the stomach with hot water night and morning. How far the influenza in this case was responsible for the attack is, of course, difficult to say, but when I saw him first he was very insistent that it was the cause of his whole trouble. From the rapid way in which the attacks have ameliorated and his present general condition there is, to say the least, a strong probability that it is functional and not associated with organic disease.

The other case was that of the late chief justice of this State, who had, in the early winter of 1893, a very severe attack of influenza with much fever and prostration. In the latter part of December he began to have pain about the heart in walking briskly up a hill. Then he had more severe attacks, but in the summer of 1894 he was better, and was able to take long walks. The attacks recurred about Christmas, 1894. I saw him on January 20, 1895. There was no enlargement of the heart, the sounds were clear, the second aortic a little accentuated. The only striking anomaly was a condition of trigeminal heart-beats—groups of three beats, with an interval, followed in regular sequence. He improved very much through the summer of 1895. In October he had a severe shock on the sudden death from angina of his brother-in-law (Case XXXV on my list). He did not, however, have any recurrence until December. I saw him on January 5, 1896. The paroxysms had become more frequent and very severe. In the following week he died in an unusually prolonged attack. The onset of the angina corresponded with the period of convalescence from the influenza, which he always insisted had caused the attacks.

**HEART DISEASE.**—Paroxysms of agonizing substernal pain, with radiation to the neck and arm, are rare in the ordinary forms of heart disease which we meet with in hospital work. Heart pain is common enough, and if we counted all such cases as angina we would not have to lay stress on the infrequency of this syndrome in the wards. You remember the small boy in Ward F during the early part of this session, with greatly enlarged heart, probably from pericardial adhesions. Pain was the most distressing symptom of the case, but it had neither the intensity, the paroxysmal character, nor the accompaniments which warrant the diagnosis of true angina. So, too, in the case of the old colored woman, at present in Ward O, with mitral-valve disease and extreme arteriosclerosis. I have pointed out to you that the attacks of sudden breathlessness and distress, with transient pain, are of the nature of cardiac asthma, with which, as I will tell you later, angina pectoris is often confounded. Then again, you have to bear in mind the common complaint of pain beneath the left breast in patients with chlorosis and various forms of anaemia.

Of valvular affections, aortic insufficiency is that with which angina pectoris is most frequently associated. Of the forty cases in my list three presented signs of this lesion. The subjects of the degenerative type of the disease, which develops in men after the fortieth year, are much more prone to angina than those in whom the insufficiency has followed endocarditis. The younger the subject, the greater the probability that the incompetency results from an acute aortitis, as in Corrigan's case, to which I have referred on several occasions.

Angina pectoris is excessively rare in mitral-valve disease. This is well illustrated by Nothnagel's experience.\* Of fifteen hundred cases of valvular disease of the heart seen in hospital and private practice, very many of which had symptoms of angina, there was but a single case in which the syndrome occurred in connection with mitral stenosis. Only one of my cases, a woman, had a mitral lesion. By far the most common heart disease with which angina is associated is chronic myocarditis, the signs of which are often dubious.

Cases of adherent pericardium and of aneurysm of the aortic arch may present the features of typical angina, more often, in my experience, of constant substernal pain or of cervico-brachial neuralgia.

A majority of the subjects of angina present the signs of arterio-sclerosis, with accentuation of the aortic second sound and slight increase in the area of transverse heart dullness. Some of the most rapidly fatal cases are those in which the physical signs are very slight, or even absent. Of the cases on my list, in four only was the physical examination negative; three presented apical or basic murmurs; of the remainder, all of whom showed signs of sclerosis of the arteries, nine had indications of myocardial changes.

**LOCOMOTOR ATAXIA.**—Considering the close relationship of syphilis to this disease, in which also arterio-sclerosis is so common, it is not surprising that attacks of angina pectoris should occur. No instance has fallen under my personal observation. You know that aortic insufficiency is not rare in tabes. At Blockley the association was a matter of everyday comment, and in the physical-diagnosis class we would send to the out wards for the old tabetics to demonstrate the lesions of arterio-sclerosis, and if not of aortic incompetency, of the ringing metallic aortic second sound, which so often accompanies the dilated and rigid aortic arch. You will find the subject fully discussed by Leyden in the *Zeitschrift f. klin. Medicin* for 1887, and since his paper there have been several less important communications.

**GENERAL PICTURE OF THE DISEASE.**—In any long series of cases of angina we can recognize four groups:

I. *Sudden Death, without other Manifestations of Angina Pectoris.*—Much more true of angina pectoris is what Andral said of the fulminant form of cholera: it begins where other diseases end—in death. The affec-

\* *Verhandlungen des Congresses f. innere Medicin*, Bd. x.

tion has indeed been called by Sir Walter Foster a mode of death, which reminds one of the expression of the physicians who spoke of Seneca's malady as a *meditatio mortis*. No inconsiderable proportion of sudden deaths in men of middle age and robust habits result from coronary-artery disease, from the rapid culmination, so to speak, of a condition which, in another (or on previous occasions in the individual himself), would have caused an ordinary attack of angina. Before all is over there may be a momentary conscious agony expressed by a cry, but in other instances (and this is most frequently the case in the subjects of angina) the death is literally instantaneous; more rapid, perhaps, than that which occurs by any other mode.

Of the fifteen deaths in my series, eight took place suddenly; in five, gradually by cardiac asystole; in one, I did not learn the exact mode of death; in another, the patient died of obstruction of the bowels. Of the eight cases, in five death was sudden, almost without warning, and not in a paroxysm of angina.

Mr. S. (Case XXVI) died on his doorstep; Mr. W. (Case XXVII) died as he was leaving a friend's house; Dr. X. (Case VIII) died as he was walking from one room to another. He had had cardiac arrhythmia, Cheyne-Stokes breathing, and marked mental disturbance; Mr. E. (Case XXXV) died instantly on the edge of the bed as he was recovering from his first attack of angina, not having had pains for nearly twenty-four hours; Mr. R. (Case XI) fell over dead on attempting to get out of bed. The literature abounds in cases of this sort, and the proportion of the victims of angina who die abruptly is much larger than my figures indicate. Forbes mentions that of sixty-four cases sudden death occurred in forty-nine. Anatomically it has been shown that lesion of the coronary arteries is almost invariably present—either extensive arteriosclerosis, embolism, thrombosis, or in rare instances the bursting of a small atheromatous abscess in one vessel, such as killed the celebrated sculptor Thorwaldsen.\* An explanation of the awful suddenness—"Life struck sharp on Death"—is probably to be found in the arrest of the heart in fibrillary contraction, such as takes place experimentally in animals after ligation of a coronary vessel.

II. *Death in the First Well-marked Paroxysm.*—A man in full health, in the prime of life, may be seized with a paroxysm of angina, and die within a few hours. The cases in this category are not numerous. Perhaps the most remarkable one on record, which has become quite historic, is that of the celebrated Dr. Arnold, of Rugby, who, in the words of his distinguished son (also a victim of the disease), arose

" . . . to tread  
In the summer morning, the road  
Of death, at a call unforeseen,  
Sudden."

The following is Latham's account:\*

"T. A. was within a day of completing his forty-seventh year. Up to a few hours before his death, both body and mind seemed equally to give proof and promise of health. He still took his accustomed pleasure and refreshment in strenuous exercise. His thoughts were still busily employed upon the highest subjects, conceiving and composing with wonderful ease, rapidity, and power. He retired to rest at midnight on the 11th of June, 1842, feeling and believing himself to be in perfect health. At a quarter before seven the next morning his medical attendant was called. What had previously occurred and what followed I will give in the words of Dr. Bucknill, who was with him during the short remaining period of his existence. 'On my entering his room he said that he was sorry to disturb me so soon; and that he had not sent for me before, thinking that it would go off. He added, "I have had very severe pain in the chest since five o'clock, at intervals, and it gets worse, I think." This pain was seated at the upper part of the chest, toward the left side, and extended down the left arm. He had been rather sick. He then asked me what the pain was. "What is it?" He was now almost free from pain. His pulse I could scarcely feel. The tongue was clean. There was cold perspiration over his face. The feet and legs were cool. The breathing at this time not troubled. I gave him immediately some hot, strong brandy and water, and having ordered a mustard plaster for his chest, till this was ready I applied hot flannels, and had his legs and arms rubbed and the feet wrapped up in flannels wrung out of hot water and mustard. The pulse became natural, the extremities more warm, and he was free from pain. The mustard plaster was brought and put on. It was not large enough and I ordered another. The pain then returning, I gave him more brandy and water, and it soon left him. And now he asked me again what the pain was. I told him I believed it was spasm of the heart. He exclaimed, "Ah!" I asked him whether he had ever fainted in his life. "No, never." If he had at any time difficulty of breathing, "No, never." If any pain in his chest before, "No, never." I then asked him if any of his family had ever had any disease of the chest. "Yes, my father had; he died of it." He inquired if disease of the heart was suddenly fatal. I answered that it was. "Was it a common disease?" I said not very common. "Where do you find it most?" "In large towns, I think." "Why?" "Perhaps from anxiety and eager competition among the higher, and intemperance among the lower classes." He was then quiet and free from pain, and I proposed to leave him for a minute or two. He had no pain whatever in my absence. On my return the perspiration was still in drops upon his forehead. The pulse was again feeble, and I gave him more brandy and water and had the flannels with mustard renewed. An attack of pain was coming on. He said, "I must stretch myself." I took one of his hands and held it until the pain was gone off. It was of short duration. I said, "Is it gone?" He answered, "Yes, entirely," adding that he "could scarcely bear it if it were as severe as it had been." He then asked me "what was the general cause of this kind of disease." He then said, "Is this likely to return?" I answered that I was afraid it was, but that, as the attacks had been less severe and less frequent, I hoped they would pass off. He next asked me

\* Latham's *Works*, vol. i, p. 453; New Sydenham Society, 1876.  
See also Stanley's *Life of Thomas Arnold*.

\* Virchow's *Archiv*, Bd. xxv.

if the disease was generally suddenly fatal. I said generally (for those who knew him were aware that it was impossible not to tell him the exact truth). I then asked him if he had any pain. He said, "None but from the blister; one can bear outward pain, but it is not so easy to bear inward pain." I was now dropping some laudanum into a wineglass, when he inquired what I was going to give him. I told him laudanum, Hoffman's anodyne, and camphor; and, while I was preparing the mixture, and before I had finished, I heard a rattling in the throat and a convulsive struggle. I called out, and on turning to him I supported his head, which was thrown back on my shoulder. His eyes were fixed and his teeth set, and he was insensible. His breathing was very laborious, his chest heaved, and there was a severe struggle over the upper part of the body. His pulse was imperceptible, and after deep breathings at a few prolonged intervals all was over. He died in little more than half an hour after I first saw him."

The examination showed a soft, flaccid heart muscle. There was but one coronary artery, and that, considering the size of the heart, of small dimensions. It presented also a slight atheromatous deposit an inch from its orifice.

In no case in my series did death occur in the first paroxysm. The most rapid case was Mr. E. (Case XXXV), who had an agonizing paroxysm at 2.30 P. M. on October 14th, and several lesser recurrences through out the night. There was no attack on the 15th, and he passed a comfortable night. On the 16th, at 9.10 A. M., he sat up on the edge of the bed to be helped on the commode, and fell over dead, about forty-two hours from the onset of the first attack.

III. *Recurring Attacks extending over a Period of Months or Years.*—Much more commonly a victim of angina pectoris has many paroxysms over a period of many months, or from three or four to twenty or even twenty-five years. The recurrences may be at long intervals, as in John Hunter's case, or they may render the patient's life unbearable, since he feels that the slightest transgression, muscular or emotional, may precipitate a paroxysm. Many a poor sufferer has felt what Senator Sumner expressed: "This treacherous disease produces in my mind a positive uncertainty, when I go out of my house, whether I shall ever enter it again a living man, and, with the pain I have to suffer, makes my life such a burden that the sooner it does its work the better I shall be pleased. Life, at the price I have to pay, is not worth the having." Let me read you the history of a typical case of this sort:

CASE XXVI.—Mr. X., an editor by occupation, aged fifty-five, consulted me January 16, 1894, complaining of attacks of agonizing pain in the region of the heart. The patient was of a nervous temperament, but had been a very healthy man. He had never done hard physical work and had been moderate in the use of alcohol and tobacco. He did not think that he had ever had syphilis. Three years ago, following upon the shock of the announcement of the suicide of a son, he had his first attack of severe pain about the heart. Ever since, the attacks have recurred at irregular intervals, at first of a few weeks or a month, but within the past year they have been very frequent, so that he now rarely passes a day without paroxysms. They vary a great deal

in intensity. If he walks fast or makes any unusual exertion he is stopped by an intense pain in the heart, and he has to pant for breath. After lasting for half a minute or so the pain passes off, and he is able to resume his walk. Any unusual emotion or excitement will bring on an attack at once. He not uncommonly now has as many as a dozen or more attacks in the day. In the severer paroxysms he feels as if the throat was greatly swollen, and says that both his throat and his temples throb, and that he gets very red in the face. As the attacks pass off he usually sweats quite profusely. From what I can gather, he did not appear to have had paroxysms of terrible agony, in which the sense of impending death was present. He says, however, that the feeling is as though the heart was grasped in a vise, and the pains shoot up the neck and down the left arm. Two weeks ago, in Philadelphia, while walking to the station, he felt an excessively severe pain in the chest, became short of breath, and fell unconscious. When he recovered he found himself in a neighboring chemist's shop. He was able, however, to proceed on his journey. While in my waiting room this patient had two attacks, and while I was examining him he had a third, the phenomena of which I will describe to you later. Three days after his visit to me, while walking up the steps of his house, he dropped dead.

The great majority of all cases of angina pectoris come in this group.

IV. *Rapidly Repeated Attacks over a Period of Days or Weeks, with the Development of a State of Cardiac Astylosis—État de mal angineux.*—An individual in apparently good health, who may not have had any indications of heart trouble, or who may have had at some previous date an attack of angina, is seized with a severe paroxysm. This passes away, but there is shortly a recurrence, and for several days in rapid succession there are subintrant attacks, with increasing weakness of the heart. Huchard describes the condition as *l'état de mal angineux*. In a way, it is a counterpart of the status epilepticus. The condition is one of terrible distress. I have seen but two cases, and as this feature of the disease has not been specially dwelt upon by writers, except Huchard, I will read you an abstract of them both.

CASE XXXII.—On January 3, 1894, I saw with Dr. Pole, Mr. L., aged fifty-five years, merchant, who for a week had had attacks of severe pain in the region of the heart.

The patient was a stout, large-framed man, who had lived for many years a life of great activity. He had always enjoyed very excellent health; never had had rheumatism. He has seven healthy children. He had been a moderate smoker and moderate drinker, chiefly of beer. He had not had syphilis. Seven years ago, after a slight exertion, he had a very severe attack of pain about the heart, which lasted, however, only a day and then passed off. He had no recurrence and had been very well, though, occasionally, he has been a little short of breath on walking rapidly. A week ago, December 27th, a fire occurred in his place of business, and he was naturally very much excited, and helped to save the papers and books. That night he had a severe attack of angina pectoris, accompanied with vomiting and sweating. He was better the next day and able to go out. Since then he has had three attacks, all of them of a good deal of

severity. He feels very weak and feeble and the pains are severe enough to require morphine. Last night they were very much worse.

He was a well-nourished, healthy-looking man. The pulse was about 90, and there was no increase in tension; the radials were not sclerotic, and though the temporals stood out prominently, they were not firm. During the examination, the patient had an attack of very severe pain, and clapping his hands over the heart rolled about upon the bed. He was flushed in the face, and then broke out into a profuse perspiration. During the attack the pulse did not change materially in character, but remained regular. The pain was described as very intense, a feeling as if the heart was grasped in something. It extended also down the left arm and in very severe paroxysms also down the right arm. The apex-beat was difficult to feel on account of the fat mamma. The cardiac dullness was not increased. The sounds were clear at apex and base; the aortic second was not accentuated. The lungs were clear on percussion and the breath sounds were normal.

The abdomen was distended and the stomach tympany was high. As nitroglycerin and nitrite of amyl had no influence whatever on his attacks, morphine was used.

On the 4th he was better. On the 5th and 6th he had very severe attacks, requiring much morphine. On the 7th and 8th he was still worse, and displayed a remarkable resistance to the morphine. Thus, in the hours between ten o'clock Saturday night and 1 p. m. on Sunday, he had received by mouth and by hypodermic injection five grains of morphine, in spite of which he scarcely slept at all, and, at the time of the visit, the pupils, though small, were not extremely contracted. So resistant had he appeared to be to the morphine that we discarded the tablets which had been employed and obtained a fresh solution. The attacks of pain were of great intensity and recurred frequently. They were of the sharp, agonizing form, and in the intervals there was a dull, heavy weight. Only the fullest doses of morphine on Sunday and Monday kept him free from pain. On Tuesday he was somewhat better, and on Wednesday he was almost free.

During these protracted attacks he was frequently almost beside himself with the pain, and sweated very profusely, and on Sunday and Monday and Tuesday he had severe attacks of vomiting. There was no fever. On Wednesday, the 10th, he was better. I saw him early on the morning of the 11th. He had had a bad night with the shortness of breath. I found him with a pulse of 115, small in volume; the heart sounds feeble and distant. The change, so far as his heart was concerned, was quite striking, as the heart sounds had previously been quite clear. To-day they were extremely feeble and the action somewhat irregular. Over the left lung there were numerous bronchial râles, particularly on the outer side. In the evening his condition seemed really critical. The respirations were 40, labored; expiration prolonged, and there were medium-sized râles heard over the whole chest. He was given whisky freely, Hoffmann's anodyne, and ammonia, and in spite of the threatening condition in his lungs he was given during the night two or three hypodermics of morphine.

On the 12th and 13th the cardiac condition was better. He had had no attacks of pain since Wednesday. The bronchial symptoms and cough continued.

On the 14th he was not nearly so well. The respirations were hurried, the cough troublesome, and over the whole chest piping rhonchi were heard. The pulse was at about 120 and feeble. He took his nourishment bet-

ter, and the feeling of weight about the heart had gradually diminished. All along, the color of his face had kept pretty good, though that of the finger tips was sometimes a little cyanotic.

On the 15th and 16th he was decidedly better, though the wheezing rhonchi were still present everywhere. His expectoration throughout these attacks had been mucopurulent, and then purulent, but the cough was never paroxysmal. On several occasions the urine presented slight traces of albumin.

January 21st. For the past few days the condition had been better, little or no pain, less wheezing, and he has been sleeping better and taking more food. Last evening, however, he had hallucinations, and did not know where he was, thinking he was in some hospital, and that his wife was his mother-in-law. He seemed, however, so well that they thought partly that he was joking. His wife stated, too, that on several occasions during his illness he had made odd remarks, as if he did not realize fully his surroundings. He spoke of it himself this morning and joked about it, seeming quite clear and bright mentally. The pulse was soft, 90, regular, and without increase in tension; the heart sounds were a little feeble, but clear. The bronchial râles were still to be heard everywhere over the chest. I left him, saying that as he was so much better I probably would not see him again.

22d. Dr. Pole sent word that the patient died suddenly at 2.45 this afternoon. He wrote: "I saw him about one o'clock, after he had had a severe heart pang, which he described as of a very sharp, cutting character, and he felt as though his heart had stopped. The color changed as usual. He had been cold all day at the extremities, though not more so than he had frequently been before. He rested fairly well last night and took no morphine, but throughout the day he has had cutting pains in his left hypochondriac region."

CASE XXXVIII.—On the 24th of February, 1896, I saw, at 10.30 a. m., with Dr. Mary Sherwood, Mr. L., aged fifty-nine years, who had been attacked at seven o'clock in the morning with agonizing substernal pain.

He was a healthy man of good stock; his mother, still living, was aged nearly ninety; his father died about the age of sixty, of, so it is said, fatty heart. The patient had been an abstemious man, of good habits, not a heavy smoker. During the past thirty years he had scarcely had a day's illness. For a year or more he had been using the bicycle, and had noticed that he was a good deal distressed and short of breath on going up hill. For several weeks he has had occasional attacks of pain of a singular character about the wrists, chiefly the left, which, he said, felt as if encircled by a band. He has occasionally felt pain about the elbow and the left shoulder. They did not seem to be rheumatic. Yesterday he had a very comfortable day, took a light evening meal, and went to bed feeling in his usual health. He was aroused this morning at seven o'clock with a very severe pain beneath the breastbone. It extended to the region of the apex, and was felt very severely down the left arm and about both wrists. He became pale, but Dr. Sherwood, who saw him about half-past seven, said that the pulse was not much affected. He obtained temporary relief by inhalations of the nitrite of amyl, but between eight and nine it became so severe that he had to be given whiffs of chloroform.

I saw him at 10.30. He was a healthy-looking man, with grayish hair and mustaches; there was no arcus senilis. He was not sweating, and he did not look very

greatly distressed. The pulse was 90, of fair volume, without increase of tension, and the coats of the vessel were not specially thickened. The apex-beat was not easily to be felt. The heart sounds were dull and muffled at apex; there was no murmur at the base. The aortic second sound was not accentuated. There was no dullness over the manubrium. He had no respiratory distress, and there were no piping râles. The abdomen was not distended.

The intensity of the pain had passed, but he was still suffering a great deal from a very severe constant pain beneath the breastbone. He had not had any sweating or special coldness of the hands or feet. He was ordered a quarter of a grain of morphine, and to have it repeated at intervals if necessary. He improved somewhat through the day, though the pain did not entirely disappear. He had a pretty comfortable night.

On Tuesday, the 25th, he seemed better. He had five or six free movements from the bowels, and, as he insisted upon walking to the water-closet, they exhausted him a good deal.

On Wednesday, the 26th, without any active paroxysm, he had a great deal of substernal pain, and his pulse became feebler. He dreaded very much a return of the severe pain, and had small doses of morphine at intervals. I did not see him again until Thursday at 2 P. M. He had not had a good night, and had become much worse through the morning, signs of great cardiac weakness having appeared. He had had no sweating. When I saw him he was greatly changed. The pallor was marked, and the general depression extreme. There was no sweating; the face was pale, rather than ashy gray. The tongue was thickly furred. His mind was quite clear, and he complained only of feelings of great exhaustion and an uneasy pain beneath the sternum. The head was low; the respirations were not hurried. The pulse was scarcely to be counted, only a few feeble beats reaching the wrist. There was no heaving over the præcordia; the sounds at the apex were only just audible in gallop rhythm. At the base the gallop rhythm could just be perceived. There seemed to be a slight increase in the area of cardiac dullness. He had been having hypodermics of strychnine, one sixtieth, but one thirtieth was ordered every two hours, and a hundredth of a grain of digitalin. He had passed very small quantities of urine. At ten o'clock that evening he was decidedly better; the pulse was stronger and the beats were regular. There was still slight gallop rhythm at the apex. The sounds were very much more distinct. He complained a good deal of an unpleasant gasping in his breathing at intervals, which distressed him very much.

February 28th. Patient had had a rather restless night, sleeping only at intervals, and being much distressed by gasping for breath. He had taken small quantities of nourishment, and had had no vomiting. The pulse was regular, small, and about the same as last evening. He had had digitalin and strychnine regularly through the night. He had a very comfortable day, and seemed altogether better, though he had had some slight delirium and wandering, particularly after waking. He had slept with his head high, and had not been quite so much troubled with the cardiac asthma. He had had no attacks of pain.

29th. This morning he was not so well. He had had a quarter of a grain of morphine at ten last night, which quieted him, but he was aroused at intervals with a distressing sense of the need of air. The delirium was marked and he looked distressed; there was no coldness

of the hands and feet, and no sweating. The pulse was feeble, irregular, and intermittent; sometimes three and four beats were dropped in succession. The apex-beat was not palpable. The heart sounds were only just audible at the apex. There was a gallop rhythm. At the base the second sound could only just be heard. There was no murmur. Throughout the day he was quiet, except for attacks of gasping for breath, which were very distressing. At 5.30 the pulse could not be felt at the wrist. He was conscious; the respirations were not hurried, though every five or ten minutes he would become a little restless and gasp. The heart sounds could be heard both at apex and base; a very distinct embryocardia, but no murmur. The feet and hands were cold, but he had had no sweating. It was rather remarkable to see a man in such a desperate condition entirely conscious and perfectly alive to his surroundings. He was at times very nervous and restless. Throughout the evening he grew worse; the heart sounds became feebler, and after a period of terrible distress for an hour or more, death occurred, about six days after the onset of the first paroxysm.

### TREATMENT OF CHRONIC DISEASE OF THE ANKLE AND TARSUS.\*

By W. R. TOWNSEND, A. M., M. D.

IN the treatment of chronic disease of the ankle and tarsus the majority of authorities believe that, in mild

cases, the best results are obtained by giving the joint complete rest and protection; that in the more severe

\* Read before the Society of Alumni of Bellevue Hospital, May 6, 1896.

cases operative interference is necessary, and that complete removal of diseased bones gives better results than partial scraping or gouging. There are, however, some who believe that all cases are best treated by means of active surgical interference, and that as soon as abscesses appear it is best to cut down and either do a complete excision of the tibio-tarsal articulation (which means, in most cases, a complete removal of the astragalus), or of any of the tarsal bones which may be affected. For those who are interested in a complete statement of both sides I would refer them to the article on the subject of the operative treatment of this disease, by C. L. Scudder, M. D., to be found in the second volume of the *Transactions of the American Orthopaedic Association*. In this he quotes the results of his own cases and those of other observers, and in the discussion a full statement is given of the non-operative side of the case. My experience leads me to believe that most cases can be treated by conservative measures, that proper rest to the articulation will give a complete cure, and that such a foot, when cured, is always better than one that has been subjected to operative interference. I recognize, however, that cases have been reported where complete restoration of bone has occurred after subperiosteal operations. I also fully believe that if treatment is begun early, the tendency to abscesses and the extension of the disease from its original focus is much diminished. The proper mechanical treatment is a matter of the utmost importance, and it is this fact that I wish to emphasize, and to call attention to a method which in my hands has given great satisfaction. That a great many do not thoroughly appreciate what complete rest and protection for the ankle joint means is evidenced by the fact that during the past year I have seen five cases of ankle-joint disease in which imperfect measures had been adopted, and of necessity the cases were not doing well. In all of these, plaster-of-Paris casts had been applied about the foot; in three, the casts were put on with the foot in a proper position—namely, at a right angle with the leg; in the other two, the foot was in marked equinus, and so held by the plaster of Paris. It is important, if we are to get any results by non-operative measures, that complete and perfect rest be given to the articulation; this can only be done by putting the patients on crutches or on a brace, so that they can walk without touching the foot to the ground, a high shoe being placed under the sound foot. Crutches answer very well for children old enough to appreciate what is needed of them and for adults, but are entirely useless for very young children, and a suitable brace can be used for both young and old. I might state here that the class of cases that I believe best adapted to brace treatment are those occurring during the first two decades of life; after that age the subject must be looked at somewhat differently, and, although conservatism should be used, yet operative interference is more needed than in earlier life. In a case in which plaster of Paris is

applied and the foot allowed to strike the ground at each step, it does not take long for bad symptoms to result, and to have the necessity arise for operative interference, and, at the same time, conservative measures are held responsible for the bad results; this is manifestly wrong, and yet none of the different practitioners who were treating the five cases referred to was aware that he was not treating them rightly; each, no doubt, believed that the joint was protected, because the patient could not move the foot, or at least could move it but very little. This same result often occurs when young patients are given crutches. Despite the fact that the shoe on the well foot is raised, they will frequently walk on the plaster cast. This could be obviated if the shoe were raised three or four inches, or to such a height that locomotion would be simply impossible, owing to the great difference in length between the two legs; but we frequently see shoes only raised an inch, and, of course, with such a slight difference patients can easily walk. If the cork sole or metal patten under the shoe is properly made, it is better to have the sole raised for children two inches, and for adults from three to four inches, because then, even without a plaster cast, the patient can not touch the toes to the ground. Before speaking of the splint that I recommend for such cases, I should like to call attention to one other point in the treatment which has been brought to my attention, also within the past year by two other patients who had suffered from ankle-joint disease and had had excisions done for their relief. I was then asked to apply suitable braces so that they could walk. In both instances no ankylosis had occurred and the joints were absolutely flail, and the only thing possible to do was to recommend an amputation so that an artificial foot could be applied. In one of these patients such a procedure was carried out, and she now walks well; the other case was lost track of. The point of interest is that, at the best, excision of the ankle in many cases of extensive disease is a difficult and unsatisfactory procedure, and unless the result is a good ankylosis an amputation had better be first done. Of course, ankylosis may have been aimed at and a failure result, but where so much bone is removed that the lower end of the leg is nowhere in close contact with the bones of the foot, nothing but a flail joint can result, and for that it is difficult to arrange suitable prothetic apparatus. A proper and suitable excision may give a very good result.

The method of treatment that I can confidently recommend for these cases is to immobilize the foot by means of a light plaster-of-Paris or silicate-of-sodium bandage, or any of the other materials used for such purpose, such as leather, felt, wood, or paper. The foot should be held in a proper position, which is a slight amount of varus, and as near a right angle to the leg as possible; the equinus is bad, for the reason that the heel cord becomes shortened, the muscles in front of the foot and leg are stretched, and, although the patient

may entirely recover from the disease, yet a deformity of the foot results. The plaster is put on snugly and but little if any padding is needed. As soon as it is nearly hard it is cut down, and, when dry, leather strips are fastened to the edges, in which are either shoe fasteners or holes, so that a lacing can be used. The foot is thus kept absolutely quiet, and if swelling occurs the plaster does not exert undue pressure. The brace used is the ordinary Thomas knee brace, and is a very simple and inexpensive apparatus. Where plaster of Paris is used, no foot rest is necessary, and, in fact, the foot rest, while theoretically a good attachment, practically is not of much use, the reason being that it is difficult to prevent a certain amount of jarring of the foot, no matter how perfectly it is made. The "Thomas splint" consists of a ring of metal and two side bars extending to the ground, which may terminate in two rubber crutch tips, or the two ends may be fastened to a foot piece of metal, under which we have leather or rubber. The inner bar is made from two to four inches shorter than the outer bar, according to the age of the child, and this difference may be somewhat varied to suit individual cases. A leather trough is placed behind the limb and the limb held to it by means of either a bandage or leather strap. The ring itself is best made over a cone of metal which represents the actual contour of the thigh. Its measurement is taken at a point as high up on the inner side of the thigh as possible, and from that the tape should encircle the thigh, touching about the trochanter on the outer side. The ring should fit snugly but not tightly. The best material for padding the ring is an old blanket, and for a covering over this either leather or rubber tubing may be used. I have applied the splint to children of eighteen months of age and in adults of forty, so that it can be seen that the brace is suitable to all ages. The skin should be kept dry, hardened possibly by the use of a little alcohol and water, and a proper dusting powder used if necessary. Cleanliness and care will prevent rubbing and excoriations, and this fact must be insisted upon. To the ring it is advisable to attach in front and behind buckles, so that the brace may be held up by suspenders passing over the shoulders and thus prevented from dropping when the patient takes a step forward. In addition to the brace treatment, proper attention should be paid to the general constitution, and iodoform injections into the joint or Biers's method of passive congestion may be advantageously employed in many instances. Other little details in the management of the cases will readily suggest themselves, and I believe if they are diagnosed early, and this method of treatment pursued, especially in young children, that excisions and other operative measures would be less often indicated.

28 WEST FIFTY-NINTH STREET.

**The Death of Dr. Nicaise, of the Paris Faculty of Medicine,** is announced in the *Journal des praticiens* as having taken place on the 3d of August.

## HYSTERECTOMY,

WITH SPECIAL REFERENCE TO  
THE TECHNIQUE OF THE VAGINAL ROUTE.  
A REPORT OF EIGHT CASES.\*

By FREDERICK HOLME WIGGIN, M.D.,  
VISITING GYNECOLOGIST TO THE NEW YORK CITY HOSPITAL,  
BLACKWELL'S ISLAND, AND SURGEON TO ST. ELIZABETH'S HOSPITAL.

So much attention is concentrated at the present time upon everything pertaining to hysterectomy, especially upon the selection of the route by which the uterus shall be attacked—whether vaginally or abdominally—as well as upon the indications for its performance, its technics, and its results, by those interested in the department of surgery known as gynecology, that the following observations and reports of cases may prove of interest, and serve as an introduction to the further discussion of this important subject.

The chief indications for the performance of hysterectomy may be stated as follows:

1. Uterine neoplasms.
2. Tubular or ovarian disease, when the organs on both sides are affected.
3. Ectopic pregnancy, when the tube opposite to the one in which gestation occurs is diseased.
4. Some cases of puerperal sepsis.
5. Some cases of pelvic suppuration.
6. Metrorrhagia due to endometritis, when the patient is very anæmic and other means have failed to afford relief.

The selection of the method, whether vaginal, abdominal, or a combination of the two, by means of which the diseased uterus shall be removed, will at the present time depend largely upon the size, benignity, or malignity of the tumor, and upon the character of the adhesions which exist in a given case, as well as upon the personal experience and predilection of the individual operator.

Wathen, of Louisville, Ky., in the course of a recent article on Vaginal Hysterectomy, in the *American Journal of Obstetrics and Diseases of Women*, August, 1895, said: "The dangers of immediate and secondary hemorrhage, wounding the bladder, ureters, or intestines, and the difficulty of maintaining asepsis, are arguments used against vaginal hysterectomy, but these objections are not well founded, and the experience of Péan, Richelot, Segond, Jacobs, and others, has proved that these dangers are less than in coliotomy."

The results following upon the performance of hysterectomy by the average operator may be stated at the present time to be represented by a rate of mortality of fifteen per cent., whether the vaginal or abdominal route is followed; while in the hands of more experienced men the death-rate has fallen as low as 2.9 per cent. This latter result has been recorded by Jacobs as following upon four hundred and three uterine extirpations by the vaginal route performed by him.

\* Read before the Society of Alumni of Bellevue Hospital, June 3, 1896.

The patient is best prepared for the operation by the administration of a cathartic on the evening of the third day preceding the time set for its performance, rather than by administering it, as is usually the case, on the previous evening. The longer interval allows the patient to recover from the depressing effect of the medicine. During this time solid food should not be allowed, and each evening the patient should be given a warm bath, and a vaginal douche of boric-acid and bichloride solutions after the bath and douche have been given on the evening prior to the day of operation. The abdominal wall, thighs, and external genitals should be shaved, and, after thorough washing with a bichloride solution, a compress wet with the same is applied, and bound on to the abdominal wall over the site of the proposed or possible incision. It is allowed to remain in place until the patient is placed on the operating table, or until it is desired to incise the abdominal wall. It is well, in all cases, to prepare the patient, as has been described, for both a vaginal and an abdominal operation, for it frequently happens that the operator, beginning his work by one route, is obliged to finish by the other.

The operation should be performed as early in the day as possible. If, however, it must be postponed until the afternoon, the patient may, on awakening, be given a peptonized milk punch. A large enema should be administered at least six hours before the time set for the operation. The patient is anæsthetized, and is placed in the lithotomy position, the thighs being held in place by means of a Clover crutch. After catheterism, the external genitals and vagina are once more scrubbed, and the vagina is douched with a bichloride solution. The exposed portions of the patient's body, not in the field of operation, are covered by sterilized towels. The perinæum is retracted by means of a Simon retractor, and the cervix is seized by a bullet forceps and drawn downward. A double uterine catheter is passed into the uterine cavity, and it is washed out with a bichloride solution. The cervical canal is next cauterized with the Paquelin cautery, and is closed by sutures passed through the lips of the os. The parts are finally irrigated with bichloride and saline solutions.

The cervix is next drawn forward and upward, and the forceps held by an assistant while an incision is made around the cervix, through the vaginal wall, and then with a pair of blunt scissors, curved on the flat, the tissues are divided posteriorly until Douglas's pouch is reached. This is opened, first by an incision, and then by opening the blades of the scissors widely, divulsing the tissues. A needle, armed with silk, is now passed through the peritonæum and the posterior vaginal wall, in one or two places, and this is tied so as to prevent the slipping away of the peritonæum. The cervix is next drawn downward and forward as far as possible, and the anterior vaginal wall is picked up with another bullet forceps, about a third of an inch below the meatus urinarius, and an incision is made with a scalpel

through the anterior vaginal wall, beginning at this point and continuing to the cervix. The flaps are dissected laterally as far as possible, in order that sufficient room for manipulation may be had. Needles armed with heavy silk are passed through either flap, the silk tied, and the ends, which are left long, are held by assistants, thus retracting the tissues. A sound is introduced at this juncture into the bladder, with the curved beak turned outward, which procedure sharply defines its lower border and the union with the cervix. Below this latter point a curved transverse incision is made with a scalpel, and the bladder is separated from the uterus by blunt dissection with the fingers. This diminishes the chance of injury to the vesical wall, and, as the ureters are pushed up out of the way, there is practically little danger of their being included in the ligature which is passed about the uterine artery of either side. This obviates the necessity of employing Kelly's ureteral bougies. The vesico-uterine fold of peritonæum is next drawn down and incised by scissors. The pelvis is now elevated somewhat, and the bladder and intestines are seen to fall away from the vaginal wall and uterus. The pelvic cavity can now be explored by sight as well as by touch. A needle, armed with heavy silk, is passed as near the fundus of the uterus as possible, and the organ drawn forward. There is usually little difficulty in extracting the fundus and bringing into view the broad ligaments and the annexa. The ligaments are folded over upon themselves. A curved needle, armed with heavy silk, should be passed through this folded broad ligament on either side, and the ends left long, so that in case of hæmorrhage after the tissues are divided and retracted they may again be brought into view. The ovarian artery can be felt, and is best ligated by passing a curved needle, armed with catgut, directly around it, as little tissue being included as possible. The ligature is tied and its ends are cut off short. The round ligament is also tied in a similar manner before division. The ovarian vessels and round ligaments on both sides having been ligated and divided, the fundus is released, and the uterine vessels are secured as closely as possible to the uterus. The remaining tissues are divided, and the uterus and annexa removed.

When reliable catgut, preserved in alcohol, can be procured, it should be preferred for ligature material, as it absorbs moisture and swells rapidly after it has been applied, thus holding the parts more tightly than when it is first tied. The vaginal wound is closed, but not until the vaginal wall on either side has been attached to the stumps of the broad ligaments. After irrigation, the vagina is loosely packed with iodoform gauze. Many operators, especially the French, use clamps to secure the vessels, and while this method has the advantage of being more rapid, the ligation of the vessels is in many ways preferable, especially as it admits of the closure of the wound. The use of the clamp would seem to increase the danger of septic infection of the peritonæum, and

of the formation of intestinal adhesions. If clamps are used, they should, after their handles have been securely tied, be left in place for sixty hours, when they should be cautiously removed. The vagina is then to be douched with boric-acid solution at a low pressure, and this treatment is continued daily unless a rise of temperature occurs, in which case it should be followed by a douche of bichloride, 1 to 4,000. It is important that the elevation of the reservoir containing the fluid be not great, for there is some danger that the newly formed adhesions may be ruptured. This danger does not exist when the vessels are ligated and the wound is closed.

Usually the operation is followed by little pain; but, if the patient is restless and complains, there would seem to be no good reason why morphine should not be given.

If the conditions are such that it has been decided to extirpate the diseased uterus by means of an abdominal incision, then, after the patient has been prepared, as heretofore described, vaginally as well as abdominally, and placed under the influence of the anæsthetic, the compress is removed, and the integument is finally prepared by scrubbing and washing it with alcohol and ether and bichloride solution. The patient's chest, upper abdomen, and limbs are covered with sterilized towels, and the operator begins by opening the abdominal cavity by an incision a little to the left of the linea alba, separating the fibres of the muscle after the division of the fasciæ. After the opening of the peritoneal sac, a needle, armed with heavy silk, is passed through all the layers at several points on either side, and the ends of these sutures are left long after they are tied, so that they may be used to retract the parts as well as to prevent the separation and displacement of the different layers. The patient is next placed in the Trendelenburg position, and the tumor examined. If proved not to be of a malignant character, the procedure employed and described by Kelly in the Bulletin of the Johns Hopkins Hospital for February and March, 1896, would seem to the writer to be all that could be desired.

"The right or left ovarian vessel is ligated near the pelvic brim and a clamp is placed toward the uterus, and, cutting between ligature and clamp, the round ligament of the same side is tied off near the uterus and divided, and the two incisions connected in order to open up the top of the broad ligament. An incision is now made through the vesico-uterine peritonæum from the severed round ligament across to its fellow, freeing the bladder, which is now pushed down with a sponge so as to expose the supravaginal cervix. The body of the uterus is now pulled to the opposite side to expose the uterine artery low down on the side opened up. The vaginal portion of the cervix is located with the thumb and forefinger, and the uterine artery is seen or felt, and is tied just where it leaves the uterus. The cervix is now cut completely across just above the vaginal vault, severing the body of the uterus from the cervical stump,

which is left to close the vault. As the last fibres of the cervix are severed or pulled apart, while the body of the uterus is being drawn up, the other uterine artery comes into view, and is caught with artery forceps about an inch above the cervical stump. Rolling the uterine body still farther out, the right round ligament is clamped and cut off, and lastly, the ovarian vessels on that side are clamped and divided at the pelvic brim. Ligatures are now applied, and the operation is finished by closing the cervical tissues over the cervical canal, and then by drawing the vesical peritonæum and anterior layers of the broad ligament over the entire wound area and attaching it to the posterior peritonæum by a continuous suture."

The chief advantages alleged for this method are, the rapidity with which it can be performed, lessened danger of injuring ureters, and greater facility in shelling out subpelvic peritoneal fibroids and breaking up adhesions. The operation is finished by closing the abdominal wound without drainage.

If it is desired to use the combined method, as in cases of malignant disease of the uterus, the operation is begun by incising the vaginal mucous membrane all around the cervix, opening Douglas's pouch, separating the bladder from the anterior surface of the uterus, and ligating the uterine artery on either side of the uterus. Iodoform gauze is then placed in the vagina. The patient, after the removal of the abdominal compress and proper preparation of the abdominal integument, is placed in the Trendelenburg posture and the abdomen rapidly opened. The ovarian vessels and round ligaments are tied off and divided, and the diseased parts removed. The wound in the pelvic floor is repaired in the usual manner; the sutures are placed in the abdominal wall, passing through all the layers, and the patient is lowered into the horizontal position. The abdominal cavity is now flushed with hot saline solution, a quantity of which is allowed to remain in the cavity, and the sutures already placed in the abdominal wall are drawn up and tied loosely. The swelling of the tissues which soon follows their division is depended upon to bring the edges of the skin into close contact. Acetanilide powder is dusted over the line of the incision, and over this the usual dressing of gauze is placed, and retained in position by straps of adhesive plaster.

CASE I.—C. F., a single woman, twenty-one years of age, was admitted to the gynecological ward of the City Hospital on May 13, 1894. She stated that her first menstrual period occurred during her fifteenth year, and that her menstruation had been irregular and painful. In her seventeenth year she had had a miscarriage at six months, one week after which occurrence she had been admitted to a hospital, suffering from peritonitis (?), and had been subjected to a laparotomy, and one ovary removed. Ever since her recovery she had had constant pain in her back, in her left side, and down her left thigh. For several months prior, and at the time of her admission to the City Hospital she had suffered from metrorrhagia. Repeated cu-

retage at intervals failed to afford relief, and as the patient was anæmic, suffering much pain, and becoming exhausted, it was deemed advisable to remove the uterus. After preparation, the patient was placed under ether narcosis, and hysterectomy was performed by the combined vaginal and abdominal method. Adhesions of the viscera contained in the pelvic cavity were met with, and these proved to be very vascular when ruptured. The resulting hæmorrhage was controlled by the use of hydrogen dioxide. The remaining ovary proved to be diseased. With the exception of the occurrence of some stitch-wound infection and suppuration, the convalescence was uneventful.

CASE II.—F. C. A., a single woman, forty-two years of age, was admitted to the gynecological ward of the City Hospital early in December, 1894. She stated that her first menstrual period had occurred during her fourteenth year, and that it had been followed by regular menstruation of the monthly type. She had had two children, the last one having been born sixteen years ago. Seven weeks prior to her admission, and during her regular period, she began to flow profusely, and after this had continued for two weeks she received treatment, but the flow had continued. Vaginal examination revealed the fact that a vascular growth existed on the cervix, and a portion was removed and sent to Dr. Ira Van Gieson for microscopical examination. He pronounced it to be an epithelioma. On December 8th, after the preparation of the patient had been effected, and under ether narcosis, hysterectomy by the combined method was performed. The convalescence was uneventful, excepting for the occurrence of a superficial abscess in the incision through the abdominal wall.

CASE III.—R. M., a single woman, seventeen years of age, was admitted to the gynecological ward of the City Hospital on December 17, 1894. She stated that her first menstrual period had occurred during her eleventh year, that it had been painful, and that after the first year menstruation had been regular and of the monthly type. About one year prior to her admission she had first noticed a vaginal discharge which had since continued. It had been accompanied by severe pain in her back and abdomen, especially in the left inguinal region. Her appetite had been poor, and she had been costive. A vaginal examination revealed the fact that the uterus was anteflexed, enlarged, and tender, as were both tubes, and that there was a purulent uterine discharge. Bilateral pyosalpinx was diagnosed and, on January 17, 1895, after proper preparation, the patient was placed under ether narcosis, and abdominal hysterectomy performed. The patient's convalescence was uneventful. On January 29th it was recorded that the wound had healed, and that the patient was feeling well, and was allowed to sit up in bed. At a later period, the writer's colleague, Dr. Pryor, reported that the right ureter had been injured, and that urine escaped into the vagina.

CASE IV.—A. P., a married woman, thirty years of age, was admitted to the gynecological ward of the City Hospital on January 18, 1895. At that time she stated that she had had four children, the youngest of whom was six months of age. She also stated that her health had been good until about three months prior to her admission, when she had begun to have chills, followed by fever, to lose flesh and strength, and to suffer from severe pain in her back and lower abdomen. This was accompanied by a fetid vaginal discharge, tinged at times with blood. She had had insomnia, and had been cos-

tive. Examination showed the patient's general condition to be poor, and that her bodily temperature was 103.6° F.; that her pulse-rate was 108, and that her respirations were 28. Vaginal examination revealed the facts that a cauliflower growth existed, which involved the cervix and a limited portion of the posterior vaginal wall, and that the uterus and tubes were enlarged and tender. On January 19th, after the usual preparations, and under ether narcosis, vaginal hysterectomy was performed (Mackenrodt's incision). After removal, the tubes and ovaries were found to contain pus, and microscopical examination proved the cervical growth to be an epithelioma. The convalescence was uneventful.

CASE V.—A. W., an unmarried woman, twenty years of age, was admitted to the gynecological ward of the City Hospital on January 14, 1895. She stated that her first menstrual period had occurred during her fourteenth year, and that menstruation had been painful, but regular, and of the monthly type. She had had no children, but had had one miscarriage. For several months she had had a free vaginal discharge. Recently she had had pain in her left inguinal region, and the vaginal discharge had become more profuse. She had also suffered from pain in her head and back, and her appetite had become poor. Vaginal examination revealed the fact that both tubes and ovaries (especially those on the left side) were enlarged and tender, and also that there was a purulent discharge from the uterus. On January 22d, after the usual preparations, and under ether narcosis, vaginal hysterectomy was performed (Mackenrodt's incision). Convalescence was uneventful.

CASE VI.—At the meeting of this Society of Alumni of Bellevue Hospital, held on May 1, 1895, the writer reported the case of Mrs. E., who had been suffering from uterine myoma, and a tumor located posterior to the uterus. It was supposed to be an ovarian carcinoma, but proved to be composed of phleboliths. Vaginal hysterectomy was performed, the anterior vaginal wall being incised longitudinally. The convalescence was both rapid and uneventful.

CASE VII.—M. F.A., a married woman, thirty-eight years of age, was admitted, on January 21, 1896, to the gynecological service at the City Hospital. She stated that her first menstrual period had occurred during her tenth year, that it had been painless, regular, and of the monthly type. She had had twelve children and two miscarriages, the last a year and a half ago. Since that time her menstruation had been irregular and profuse. Five months prior to her admission the character of her menstrual discharge had changed, becoming fetid, and later it had also become light colored and watery. She had previously undergone two uterine operations the nature of which she was unable to state. She had been costive. Of late she had been losing flesh, strength, and appetite, had had night sweats, and had suffered from pain and soreness in her right inguinal region. On January 22d a thoracic examination yielded a negative result, but vaginal examination revealed the facts that the uterus was slightly enlarged, and that the cervix was indurated. Under chloroform narcosis the cervix was dilated, and some uterine tissue removed by means of the sharp curette for microscopical examination. This was made by Professor E. K. Dunham, of the Carnegie Laboratory, who reported on January 23d the results of his examination, as follows: "Although the bits of tissue you see, as the result of curetting the uterus, are very small, microscopical study of them leads

me to think your suspicions of carcinoma are well founded. I find strands of epithelium, apparently derived from the glands of the uterus, which are certainly atypical, and which even without the clinical evidence would lead me to believe that there was a beginning carcinoma."

On January 27th, the patient, after having been prepared in the usual manner and placed under ether narcosis, was subjected to vaginal hysterectomy. The anterior vaginal wall was incised, as in Mackenrodt's operation for retrodisplacement, and the technic already described followed, excepting that the ligatures were applied to the ends of the vessels instead of being passed around them with a needle, as has been the writer's usual custom. The ligatures placed on the right uterine and left ovarian arteries having been pulled on by the mistake of an assistant, they slipped off, and free hæmorrhage resulted. As the patient was already suffering from shock clamps were applied and left in place. The longitudinal incision in the anterior vaginal wall was alone closed by suture. Iodoform gauze was packed loosely into the vagina. A catheter was introduced into the bladder and retained by a catgut suture, and the dressings applied. The patient was stimulated by enemata of coffee and saline solution. Strychnine and morphine were also given hypodermically. She passed a comfortable night and was allowed to drink water freely. On January 29th the dressings, clamps, and catheter were removed, and the external genitals and vagina douched with a 1-to-4,000 bichloride solution, followed by a douche of saline solution, and external dressings only were applied. The patient was at this time placed on light diet, and her further convalescence was uneventful, her highest bodily temperature having been 100.8° F.

CASE VIII.—M. B., a married woman, forty-nine years of age, but who had not lived with her husband for twenty-five years, stated, when first seen by me on April 4, 1896, that her first menstrual period had occurred during her fifteenth year, and that menstruation had been regular, and of the monthly type, but accompanied by pain at first. She had married during her nineteenth year, and had had three children. She had had two miscarriages. Her last menstrual period had occurred during November, 1895. Two years ago the patient became aware that she had an abdominal tumor, and she suffered from bearing-down pains, accompanied by menorrhagia. The tumor gradually increased in size until November, 1895, when it began to enlarge rapidly. Abdominal palpation revealed a tumor somewhat movable, and reaching to a point a little above the umbilicus. On vaginal examination, while the tumor could not be reached, it seemed to be attached to the uterus. The patient's family physician having assured me of the fact that he had made an examination of the urine and had found it normal, a laparotomy was decided upon, and on April 12th it was performed at the patient's residence. On opening the abdominal cavity the tumor presented at once, and proved to be a large fibroid attached by a pedicle to the fundus. It was covered in front by omentum, which adhered to it, but otherwise it was free from adhesions. As the body of the uterus contained several small tumors of a like nature, it was decided to remove the uterus and annexa, as well as the tumor. This was accomplished without much difficulty. The pelvic cavity having been freely flushed with saline solution, the vaginal wound was closed. Some more saline solution was poured into the abdominal cavity and allowed to re-

main there. The wound in this wall was now closed. The operation, from the time of the administration of the anæsthetic to the closure of the abdominal wall, occupied about an hour. The patient regained consciousness promptly, and suffered but little from nausea and shock. On the following morning, when I left, her condition seemed favorable, excepting the fact that but little urine had been secreted. On the 14th her bowels moved freely after the administration of a saline cathartic, and the urinary flow seemed about to be re-established; but, in spite of all efforts, she died on the 18th.

Of the eight patients whose cases have been reported, and upon whom hysterectomy was performed, seven recovered and one died. In two instances (Cases I and II) the uterus was attacked by the combined method; in two others, by the abdominal route (Cases III and VIII); and the remaining four by the vaginal (Cases IV, V, VI, and VII).

The first case is of interest mainly on account of the condition for which the uterus was extirpated—i. e., hæmorrhagic endometritis. Sivitalski reports (*Centralblatt für Gynäkologie*, 1895, No. 33) a similar case, occurring in a woman, twenty-nine years of age, upon whom he performed hysterectomy after the failure of curettage to relieve the patient. A careful examination of the specimen threw no light upon the cause of the hæmorrhage, as the only pathological change noted was a minor degree of interstitial endometritis. The annexa in this case were normal. The patient recovered. The writer calls attention to the rare occurrence of metrorrhagia without any discoverable local or general cause, and regards it as a clear indication for total extirpation (*American Journal of the Medical Sciences*, January, 1896).

The special point of interest in the third case is the reported injury to the ureter, which did not make itself manifest till more than two weeks had elapsed after the performance of the operation. In Case VII, the operation was complicated by the slipping of the ligatures, necessitating the use of clamps to arrest the resulting hæmorrhage. In Case VIII, the neglect to make a careful examination of the patient's urine, and consequent failure to discover the existence of renal disease, led to the fatal result. Cases IV, V, VI, and VII are of interest on account of the vaginal technic employed, which has been heretofore described, and to which Vineberg has also called attention.

It is the writer's belief, founded both upon his own experience and his observation of the work of other surgeons, that while in many instances the vaginal route will prove entirely satisfactory, yet in those cases where the tumor is of large size, or firm adhesions exist, the abdominal operation and the method advocated by Kelly, of Baltimore, will prove more satisfactory; while in still another class of cases, especially those of a malignant character, the combination of the lower and upper routes, offers decided advantages over either of the other meth-

ods, and will afford the most favorable results for both the patient and operator.

55 WEST THIRTY-SIXTH STREET.

## FURTHER STATISTICS ON ECHINOCOCCUS DISEASE IN THE UNITED STATES.

By H. O. SOMMER, STUD. MED.,  
VOLUNTEER ASSISTANT, ZOOLOGICAL LABORATORY,  
BUREAU OF ANIMAL INDUSTRY.

IN vol. lxii, No. 21 of this *Journal* (1895) \* I gave a summary of sixty-seven cases of echinococcus disease recorded in medical literature for the United States. Since publishing that article I have been able to trace thirty-three other cases, thus making a total of a hundred cases compiled for this country. The additional thirty-three cases are recorded as follows:

Adding the cases given above to the tables of nationality, geographical distribution, sex, habitat, and age, we find the following statistics:

\* Helm, Böcker, Krummacher, Finsen, Neisser, and Wolff; cases recorded in other countries.

The case recorded by Ellis (1874) is of especial interest; it occurred in a seafaring man, a native of the Western Isles (Azores), who had spent part of his life in China. In Australia he was engaged as a miner and farmer, in which connection it is well to note that echinococcus disease has been frequently recognized in Australia. As the case stands reported, the conclusion very likely to be drawn is "acquired in Australia," and perhaps this is what the observer inferred; as the subject, however, was a seafaring man, a calling likely to lead him to various parts of the globe, and as there was no statement contradictory to the likelihood of his having been in other parts of the world, the deduction that he acquired the disease in Australia is not an entirely logical one. It is therefore of great importance that cases occurring in foreigners or people who have traveled in foreign parts—for instance, sailors—should be traced not only to any one known probable source of infection, but to all known possible sources of infection.

For example, the case of an Englishman from Honolulu which came under Bernays's notice in St. Louis (Osler, *Am. Jour. of the Med. Sci.*, 1882, pp. 475-478; see my former paper) is interesting, as it suggests the Sandwich Islands as a possible field of hydatid disease; but, on the other hand, the patient, being an Englishman, is evidently a traveler, and may have acquired the disease in Australia.

Another interesting case is that of a Japanese female observed by Eldridge in Washington, D. C. (*Am. Jour. of Ob.*, New York, 1881, xiv), as it is the only case I have found in the United States occurring in a native of Japan. Likewise, the case reported by Evans (*West. Lancet*, Cincinnati, 1856, xvii, pp. 680-694) is notable as the only case I have found in a native of Wales.

Since my article of last year, Van Cott, of Brooklyn, has informed me that his case occurred in a Mexican, the only case I have found in Mexicans in the United States.

I will again call attention to the opinion emphasized by Solis-Cohen, that the nativity of patients should be carefully considered, and, further, that it is to be regretted that in the cases heretofore reported nationality has been so often unstated. This lack of detail caused me to suggest the possibility that those cases in which

nationality was unstated might have occurred among foreigners, whereas, on the other hand, they may have occurred among the native-born. My attention has since been called to the fact that I omitted Freund and Chadwick's Four Cases of Echinococcus in the Female Pelvis (*Am. Jour. of Ob.*, New York, 1874-'75, vii) which I did on merely presumptive grounds. I have since been informed by Dr. Chadwick that I am correct in excluding the cases in question from American cases as they were observed by him in Dr. Freund's clinic in Breslau. In looking over the reports of cases, it soon becomes evident that it is no easy matter to exclude from or include in a collection of cases of echinococcus cases reported as such merely on the evidence submitted in the articles. Further, it is well to note here that, while the literature of the country is full of reports of cases of so-called hydatids of the uterus, and while the observers of some of the cases, possessing a slight knowledge of *Tania echinococcus*, have attributed the conditions observed by them to the rare *Tania echinococcus* of the dog, these writers have reference to other conditions known to gynecologists as uterine hydatids, pregnancy (molar, hydatiform), and not to the true hydatid of *Tania echinococcus*.

The case published by me last year as

1852. *N. Y. Med. Times*. Weber. Cyst in liver.

I have traced as

1852. *N. Y. med. Wochenschrift*, April. Weber. Liver. German. Male. 26. N. Y. city.

That of

1886. *Med. News* (Philadelphia), vol. xlv, pp. 78-9. Whittaker. Echinococcus in liver. German. Male. 60. Philadelphia.

as

*Cincinnati Lancet and Clinic*, N. S., 16, pp. 704-16. Whittaker. Echinococcus in liver. German. Male. 69. Cincinnati.

I am under especial indebtedness to Dr. Hassall for references to the new cases and to Dr. Stiles for important counsel in regard to the omission of doubtful cases, also to the gentlemen of the Surgeon-General's Library for extreme courtesy in aiding me in gathering cases.

## THE SOLVENT PROPERTIES OF THE BUFFALO LITHIA WATERS OF VIRGINIA.

By GEORGE HALSTED BOYLAND,

M. A., M. D. (PARIS), ETC.,

FORMERLY PROFESSOR IN THE BALTIMORE MEDICAL COLLEGE, ETC.

It has been said that "if we wish to ameliorate the human race, it is in medicine that we must seek the means."

Time has amply demonstrated the truth of these words, and in no department of therapeutics have so great services been rendered as in the treatment of disease by mineral waters. Experience has permitted us to add as a corollary to this, that if we wish to dissolve concretions from the blood and different viscera and prevent their reformation in the sanguineous fluid, as

well as their deposit in the organs of the body, it is the Buffalo lithia waters of Virginia that we must prescribe.

The Great Physician has provided for the sons and daughters of men a remedy so subtle in its composition and so sure in its working as to excite the wonder of the most profound chemist and the most skillful practitioner. Let these waters be analyzed and the component parts be used in precisely the same proportions, as regards weight and chemical purity, in compounding an artificial water, presenting an exact reproduction of the natural water taken from the spring, and, by some mysterious process of Nature that we know not of, their solvent power is diminished or reduced to zero. Still more inexplicable is the fact that the salts composing the Buffalo lithia waters of Virginia act with considerable rapidity in dissolving uric acid and other calculi, whether hepatic, renal, or vesical, in very weak solutions, while stronger ones are less active or fail altogether. Dr. Roberts, of London, has given us very valuable data on this subject (*vide Archives of Medicine*, vol. iii). He placed fragments of uric-acid calculi, weighing from forty to a hundred and twelve grains each, in ten-ounce phials of carbonate solutions, analogous to that found in Spring No. 2 of the Buffalo lithia waters, these solutions being of various strengths. The experiments were continued day and night for some time, the daily flow of water varying between six and fifteen pints. Operating in this way, he found that above a strength of a hundred and twenty grains to the pint no solvent action was exerted, and even with eighty grains to the pint there was only a little; but in solutions of sixty grains to the pint the solvent action was more noticeable, but began to act decidedly at fifty grains to the pint; at forty grains to the pint the activity was further increased, and so on down, the solvent action being stronger and more speedy as the strength of the solution was diminished and approached the quantities contained in the analysis of Spring No. 2, which is justly considered to be the most powerful and perfect solvent of the various forms of calculi known to science, and not of calculi only, whether of the red lithic or uric acid or the triple phosphate of ammonium-magnesium variety, but also of morbid concretions in general, such as albumin, sugar, cholesterin crystals, etc.

Many years ago, while I was resident physician at these world-renowned springs, a patient suffering from renal calculi of red uric-acid composition, wishing to assure himself of the potency of the Buffalo lithia waters as a solvent, placed a small bit of calculus passed by himself, and of about the size of the head of a large pin, in a goblet filled with the water of Spring No. 2, leaving the same covered on a shelf in his bedroom. Two weeks later he brought us the intelligence that the bit of calculus had entirely disappeared in solution with the water. Wishing in turn to verify the accuracy of a statement of such scientific importance and value, I at once undertook the follow-

ing experiments: Ten grains of a red lithic-acid calculus and an equal quantity of a triple phosphatic deposit of the whitish ammonium-magnesium formation were placed side by side in separate glass receptacles of Buffalo lithia water, Spring No. 2, containing each thirty ounces, and left standing. These vessels were not moved or touched in the slightest manner throughout the whole duration of the experiment, but remained covered with glass slabs high out of reach, for it was desired to test the solvent power exercised by the chemical action of the water upon these two typical varieties of calculi.

At the end of two weeks disintegration had already begun, and at the end of the third week the calculus had separated into three smaller fragments, which in another eight days presented a clean, water-worn appearance, with a few loose flakes floating on the surface of the water. At the end of six weeks all traces of the stone had disappeared, solution being complete. This was with the red uric or lithic-acid formation. With the other, the whitish-gray triple phosphate of ammonium-magnesium deposit, the process was somewhat different, but accomplished in the same lapse of time. Here, a whitish coating seemed to form around the original calculus, which softened it, causing it to break into many pieces resembling very coarse sand, and finally to dissipate itself and vanish altogether. The same experiment was then made with flowing water; that is, the water of Spring No. 2 was so arranged by means of a spigot and retort as to be continually renewed and to constantly wash the same amount of pebbles and of the same two varieties in the bottom of the retorts. It was found that exactly the same solvent process took place, but instead of six weeks, thirty days had sufficed to cause all traces of either stone to disappear. Analogous experiments were then undertaken with the waters of Springs Nos. 1 and 3; with the result that the water of Spring No. 1 acted a little more promptly in dissolving calculi of the triple phosphate of ammonium-magnesium than those of uric-acid concretion. Nevertheless, at the end of the thirty days dissolution was complete in both, the experiments having been carried out in every detail like those made with the water of Spring No. 2.

As regards those made with the water of Spring No. 3, the results obtained in the same manner and at the end of the same period of time, other things being equal, were as follows: Neither of the calculi was dissolved. Both, however, were carefully examined after the time prescribed by the first experiments had elapsed, and both were found to be coated with a whitish layer of about the consistence of pulp; then a second layer of the stones had become softer, the interior being slightly more friable. Neither was there any breaking into fragments, as was the case with the waters of Springs Nos. 1 and 2, and the condition of the two specimens was much the same. From this it was concluded that while the waters of Springs Nos. 1 and 2 possessed a solvent power superior to any other known mineral waters, that of

Spring No. 3 had also a solvent potency, but in a comparatively feeble degree, which furnishes a valuable therapeutic indication that will be referred to later on.

But let us come to the solvent action of the Buffalo lithia waters of Virginia inside the human body.

A chemical analysis of the waters, made by Professor William P. Tonry, of the Maryland Institute, Baltimore, gives the following results (expressed in grains to the imperial gallon):

	Spring No. 1.	Spring No. 2.	Spring No. 3.
Sulphate of magnesium.....	1-530	0-885	0-150
" aluminum.....	8-180	9-067	5-665
" potassium.....	0-465	.....	.....
" calcium.....	19-251	35-067	2-353
Carbonate of potassium.....	.....	29-309	1-852
Bicarbonate of calcium.....	39-277	14-965	2-524
" lithium.....	1-484	2-250	traces.
" iron.....	0-500	0-500	5-774
" barium.....	.....	1-750	.....
Chloride of sodium.....	1-256	4-921	0-21
" silicon.....	1-725	1-873	0-57
Phosphoric acid.....	traces.	traces.	traces.
Iodine.....	traces.	traces.	.....
Organic matter.....	small amt.	small amt.	small amt.
Total grains to the gallon....	73-666	98-376	14-47
Sulphureted hydrogen (cubic in.)...	5-9	8-3	3-4
Carbonic-acid gas (cubic in.)....	69-1	59-2	11-6

It will be observed from the analyses here appended that Spring No. 2 contains 29,300 grains of carbonate of potassium, 2,250 grains of the bicarbonate of lithium, and 4,921 grains of the chloride of sodium, a mixture made in such exact proportions when combined with the other ingredients as to surpass the most ingenious formulæ of materia medica.

Our friend and *confrère* the late Dr. J. Milner Fothergill, of London, whose authority in such matters is recognized all over the world, said: In all cases of affections of the liver and kidneys, but more especially where uric acid and lithæmia are the prominent symptoms, "soda and lithia for the liver, lithia and potash for the kidneys" (*vide Fothergill's Handbook of Treatment*) are the sovereign remedies.

My own experience covers at this late day many thousand cases in which we have prescribed and observed the solvent effects of the Buffalo lithia waters, not only at the springs themselves but in different parts of the United States and on the Continent of Europe, and I can only repeat what I have already said regarding their action when taken internally: that in the class of cases in which lithia, soda, and potash are regarded as most specially indicated I have obtained far better results from the Buffalo lithia waters than from any of the preparations of the lithium salts of the pharmacopœia; furthermore, I am satisfied that there is no other mineral water either in America or in Europe so singularly adapted to such a large number and variety of maladies.

The solvent properties of all three springs on grape sugar is immediate (as can be readily proved by placing ten or twenty grains in a test tube and adding half an

ounce of water), and their great value in the treatment of diabetes mellitus is attested by numerous cases. Although the solvent properties of these waters may be less evident *in vitro* as regards albumin, that exercised upon the albumin *in corpore* and in the blood in albuminuria and icteric fever, which it dissolves as it does the biliary elements and cholesterin crystals contained therein in the latter disease, is as remarkable as it is in lithæmia, lithiasis, and the different forms of hepatic, renal, and vesical calculi. Albumin, biliary constituents, such as cholesterine crystals and gallstones, sugar, uric acid, and phosphatic calculi are characteristic of so great a variety of diseases that they may be said to dominate all pathology; and it is because of the active solvent potency upon these different morbid concretions that the Buffalo lithia waters of Virginia are unrivaled in the treatment of so wide a range of pathological process.

It will be impossible to do more than narrate briefly one or two cases at most of each variety, from among the thousands treated by ourselves and others by these waters; the limits of a single article forbidding the introduction of long lists of cases in detail. Cases Nos. I and II are selected as typical of their class of calculi:

CASE I.—Mr. A. came to the springs with the following symptoms: constant pain in the lumbar region, being obliged to walk with his right arm across his loins as a support, of florid sanguineous temperament, nodosities of Heberden on the fingers, tongue heavily furred, passing quantities of red uric-acid gravel varying in size from the head of a pin to that of a large pea, and having had frequent attacks of nephritic colic. After a six weeks' course of the water of Spring No. 2, he returned home cured.

CASE II.—Mr. G.'s was a case of the triple phosphate of ammonium-magnesium variety. This patient was small in stature, emaciated, and pale, passing almost continuously and to a considerable amount calculi, accompanied by pain in vesical region and tenesmus of the sphincter, the urine being mixed with blood and mucus. He began upon three glasses a day of Spring No. 1, which were increased gradually to six and then to eight. At the end of ten days a decided improvement had taken place; the pain was much alleviated, the blood and mucus having entirely disappeared from the urine. In another week the calculi had taken the consistence of sand and at the end of four weeks all symptoms of disease had vanished. It was now that he was put upon the water of Spring No. 3, three glasses a day, in order to prevent the reformation of calculi and to overcome the anæmic condition.

CASE III.—Mrs. L., gallstones. This patient, like almost all others that visited the springs, had been under treatment for some time previous, having exhausted the customary remedies, such as chloroform, morphine, lithia in powders, ether in capsules, etc., without relief. The attacks had been succeeding each other every few days at the time she consulted us at the springs. Owing to some existing gastritis, the water, that of Spring No. 2, had to be begun in very small quantities, half a glass four times a day. In forty-eight hours the gastric symptoms were already alleviated and the quantity of water could be rapidly increased. This patient only

had one subsequent attack, and that shortly after her arrival at the springs, which she left at the close of the eighth week; the jaundiced color of the skin habitual with her having given place to a healthy whiteness with pink cheeks.

CASE IV. *Suppressed Gout*.—Uric acid in excess was found in the urine; there was a scarcely perceptible tophous roughness here and there along the border of the helix of the right ear, but that was all. Some emaciation. Four glasses a day of Spring No. 2, for twenty-eight days, rendered his urine perfectly normal and gave him a gain of ten pounds in weight.

CASE V. *Gout*.—This was a large, plethoric woman, weighing about two hundred pounds, who left the springs after a five weeks' course of Spring No. 2 very much benefited and having lost twenty pounds, much to her satisfaction. Repeated examinations of the urine showed it to be free from uric acid, and no crystals could be obtained after the second week; the chalky deposits and tophi in the joints had been considerably reduced in size, the smaller ones having been resorbed completely.

Unfortunately, this patient was unable to finish her course, being obliged for family reasons to return home, otherwise we should have had a *restitutio ad integrum*. By exerting their solvent power these waters accelerate the exchanges, promoting at the same time nutrition and assimilation, thereby regulating the proportion of adipose to muscular tissue.

Now follow a number of cases of lithæmia and lithiasis, which ought really to be classed as cases of uric-acid and phosphatic dyscrasiæ. Lithæmia, properly defined, is the dyscrasia of calculus or gravel, and lithiasis the complication of calculi themselves, and the term may be practically applied to all cases of spurious or abortive gout, hepatic, renal, and vesical disease characterized by mixed lithic formations not described in pathological nomenclature nor belonging to any regular pathological anatomical class. In such cases, the waters of Springs Nos. 1 and 2 act with equal promptness, purifying the blood by dissolution of the lithic elements contained therein; preventing their reformation in lithæmia and dissolving the calculi in lithiasis. In this series of cases all the calculi were of the uric-acid and triple phosphate of ammonium-magnesium varieties combined.

Stone in the bladder, whether of renal or vesical origin, and whether of oxalic, uric, or phosphatic formation, is an indication *par excellence* for the exhibition of the Buffalo lithia waters. Of the cases cured by them, perhaps the most striking is that of Mr. C., of North Carolina, who came to the springs with a large single stone in the bladder. This case places beyond all doubt the wonderful solvent power of these waters. Mr. C.'s stone, which was a triple phosphatic one, became first disintegrated into smaller fragments, these in turn into gravel, and that eventually into fine sand, until finally there was no discharge of calculous concretion in any form, and the urine, from having been strongly ammoniacal, had become perfectly normal. I received news of this

patient one year later and there had been no return of the disease.

Jaundice, which is quite a common complication in hepatic disease of almost every form and characterized by the retention in the blood of the biliary constituents, chief among which are cholesterin crystals, is quickly relieved by these waters, which dissolve the crystals and alkalize the blood.

*Albuminuria.*—These cases count by hundreds. There is no remedy so absolutely specific in all forms of albuminuria and Bright's disease, whether acute or chronic, as Buffalo lithia water, Spring No. 2, accompanied by a milk diet. In all cases of pregnancy where albumin is found in the urine as late as the last week before confinement, if this water and a milk diet are prescribed, the albumin disappears rapidly from the urine and the patient has a positive guarantee against puerperal convulsions.

We have treated quite a considerable number of diabetic and glycosuric cases with the waters of Springs Nos. 1, 2, and 3, and, where the patient persevered in the treatment to the end, with a perfect cure for a result; in others, with marked benefit; always relying upon Springs Nos. 1 and 2, at times singly and at others in combination, for the main treatment, and on Spring No. 3 as an adjuvant and chalybeate to overcome the anæmic condition usually attending such cases. The solvent action is here most marked, not only as regards the glycogen in the blood, but also the hippuric acid contained therein, and which Prout and Garrod first found in diabetic urine. (See Beale on *Urinary Deposits*.)

The two following cases of diabetes mellitus are taken from our notebook as typical of the two great classes into which all diabetic diseases are grouped—viz., *diabète gras*, fat diabetes, and thin or pancreatic diabetes.

Mr. B. was addressed to me by the late Dr. Van Bibber, of Baltimore, and when first seen by me at the springs his urine contained large quantities of sugar, three drachms to the quart, with a density of 1.045. He had marked polyphagia, polydipsia, and polyuria, being a large, fat man of the whitish type, the increase in weight coinciding with the development of the diabetic symptoms. He remained ten weeks at the springs, the quantity of sugar diminishing from the very beginning of the treatment, the appetite and abnormal thirst growing less *pari passu* until at the end of the eighth week all diabetic symptoms had entirely disappeared, he being completely restored to health; it was nevertheless considered advisable to continue the treatment two weeks longer, but in diminished quantities; four glasses of water, two of Spring No. 1 and two of Spring No. 3, were drunk during the day. This patient drank during four weeks the water of Spring No. 2 and during the second four weeks that of Spring No. 1.

The other case was that of a young lady, seventeen years of age, suffering from nervous crises, pain in the lumbar region, wasting, the urine loaded with sugar, and the patient presenting all the symptoms of pancreatic diabetes. The waters of Spring No. 2 were ordered, and fourteen days after she began to take them there was a great diminution in the quantity of sugar

observable; the nervous crises had ceased, also the pain in the lumbar region. To my regret, this young lady was now obliged to leave the springs and the case was lost sight of.

The number of cases of simple accidental glycosuria without diabetic symptoms cured by the Buffalo lithia waters is much more considerable; such cases are generally promptly relieved in a few days, sometimes in twenty-four hours.

*Appendicitis.*—Where appendicitis is dependent upon the formation of phosphatic deposit in the appendix vermiformis, the waters of Springs Nos. 1 and 2 will prevent a reformation of calculus after the operation. It is in this way that the best results will be obtained, unless it be as a prophylactic, for phosphatic appendicitis is a danger that patients with the lithic diathesis always run. During my last year as resident physician at the Buffalo lithia springs, one case of appendicitis that came under my care made a very good recovery without operation, drinking the water of Spring No. 1 throughout the entire duration of the disease.

It will be observed from the foregoing, which must be considered rather in the light of a *résumé*, that Springs Nos. 1 and 2 possess to an equal degree the solvent power which makes these waters superior to all others, not excepting the famous waters of Carlsbad. I should, however, give the preference to Spring No. 2 in all cases of the red lithic- or uric-acid dyscrasia, and to Spring No. 1 in the triple phosphate of ammonia-magnesia variety, although perhaps as many cases of the latter have been as successfully treated with the water of Spring No. 2, which is at the present day the more known to fame. I can not, in closing, insist too strongly upon the value of Spring No. 3 as an adjuvant in cases where anæmia is a symptom, not only in lithic cases but in albuminuria, diabetes, and general pathology as well. A peculiarity of the first of the two diabetic cases mentioned above was a certain proportion of inosite or muscular sugar contained in the urine. Professor Bouchard and Professor Potain, of Paris, have recently reported each a similar case.

Springs Nos. 1 and 2 hold in solution the same mineral constituents, and it is doubtless the change in their composite quantities that makes the difference in indication for their exhibition. These waters we have found equally active and efficacious in our hospital and private practice remote from the springs; the only advantages derived from drinking them *in loco* are those of change of air, scenery, and cooking, which, although valuable adjuncts are by no means essential. Of course, it must be understood that a proper diet was prescribed, and must be in every individual case while using the waters; this certainly aids their curative action, and although they are not a panacea they are at least a specific in a very large category of diseases.

Finally, were I called upon to state what mineral waters were applicable to the greatest variety of cases

in which lithia, potash, and soda are especially indicated, and what mineral waters prescribed by themselves alone, leaving medicines and diet entirely out of the question, will effect the most speedy, radical, and permanent cure in such, I should unhesitatingly answer, "The Buffalo lithia waters of Virginia." I consider the salts of lithium, as held in natural solution in these waters, far more efficacious than any pharmaceutical preparations of those salts.

PARIS.

## Therapeutical Notes.

### Inunctions of Leaf Lard in Cases of Emaciation.—

In the July number of the *American Journal of Insanity* Dr. George Boody, of the Iowa State Hospital, reports the results of experiments made by himself with leaf-lard-inunctions in cases of malnutrition with emaciation. The time over which they extended, he says, was very short and the number of cases few, but they were carefully carried out and the improvement in each case was noted. Four cases were selected, of each of which a brief account is given, with the following conclusions:

1. It clinically demonstrates that the integument plays an important rôle as an organ through which food may be taken, carried to the circulation, assimilated, nutrition improved, and wasted tissue repaired.

2. Its use is indicated in every case of extreme emaciation with malnutrition, where diet and tonic treatment with massage fails to produce the expected results.

3. It is the author's belief that if the conditions were such that food could not be taken through the stomach, nutrition could be improved and the patient made to gain in weight by inunctions of leaf lard, olive oil, or other fats, twice or three times a day.

**Iodide of Starch in Surgery.**—Majewski (*Wiener med. Presse*, 1896, No. 19; *Centralblatt für Chirurgie*, August 1, 1896) recommends iodide of starch as an excellent application in suppurating and neglected wounds, plegmons, panaritias, and venereal sores. A mixture of one part of tincture of iodine and two parts of starch, he says, exceeds iodoform in antiseptic action and in controlling suppuration. It is especially hygroscopic, almost odorless, and very agreeable.

**Male Fern in the Treatment of Tapeworm.**—In the *Revue internationale de médecine et de chirurgie* for August 10th, Dr. W. Morain attributes the following formula to Créquy:

℞ Ethereal extract of male fern. 2 drachms;  
Calomel..... 12 grains.

M. Make 16 capsules. S.: One to be taken every five minutes, fasting, until all have been swallowed. It is well, remarks Morain, to take about an ounce of castor oil in an hour after taking the last capsule. The patient should defecate into a vessel filled with water, in order to guard against the worm's breaking.

In the case of a child, the capsules can not be used, but the following preparation, attributed to Duchesne, may be employed:

℞ Ethereal oil of male fern..... 1 drachm;  
Calomel..... 6 grains;  
Water, } of each..... ½ oz.;  
Powdered sugar, }  
Gelatin..... a sufficient quantity.

M. S.: To be taken in two or three doses.

## THE NEW YORK MEDICAL JOURNAL, A Weekly Review of Medicine.

NEW YORK, SATURDAY, AUGUST 22, 1896.

### THE SERUM TREATMENT OF LEPROSY.

In the *Journal* for January 18th we mentioned a communication that had been made to the National Academy of Medicine of Bogotá by Dr. Juan De Dios Carrasquilla in which he reported cases of leprosy that had been cured or much ameliorated by the use of an antileprous serum prepared by him. It was his second paper on the subject, and was presented before the academy on the 22d of last November; the first had been laid before the same learned body on the 30th of August, 1895. By the courtesy of the academy's permanent secretary, Dr. Pablo García Medina, we have now received a copy of Dr. Carrasquilla's third communication, made on the 24th of June, 1896. In it the author describes in detail his method of obtaining the antileprous serum and his mode of employing it. These we can indicate only in outline. He first bleeds a leper, choosing an adult whose general condition is fairly good. The blood drawn varies in amount from a hundred to two hundred and fifty cubic centimetres. It is received into a sterilized vessel and carefully covered, kept away from the light, and, above all, kept perfectly quiet. In from twelve to twenty-four hours the superficial layer of serum, that only which is perfectly limpid, is removed with a pipette. If it has to be kept for some time before it is to be used, it is passed through a layer of powdered camphor contained between two layers of cotton, to preserve it, and it is kept away from light and heat.

Thus prepared, the serum is injected into an animal that is refractory to leprosy, preferably a healthy young horse in good condition. Roux's method of procedure is employed. In regard to this operation, says Dr. Carrasquilla, there are two points that are of the greatest importance and at the same time difficult to determine—the amount of serum to be injected at one time and the interval that should be allowed to elapse between the injections. His experience leads him to think that forty-five cubic centimetres is the proper medium dose, given at intervals of ten days. The horse is bled in from five to ten days after the last injection, preferably from the jugular vein. The Nocard-Roux process is followed for obtaining aseptic horse serum,

and it is treated in exactly the same way as the human serum.

The dose of the serum for use on the human subject is from one to five cubic centimetres, according to the strength of the serum, the constitution, age, and other circumstances of the patient, the period of the disease, etc., given subcutaneously. The locality to be preferred for the injection is that bounded by the iliac crest and a transverse line passing just beneath the trochanteric fossa, or, better still, just to the outer side of the trochanter major. Great care must be taken to make sure that the serum has not undergone any septic change. A full day should intervene between the injections. Febrile reaction follows in all cases, and the injection should not be repeated until this has subsided. Dr. Carrasquilla gives many other details, which we have not space to mention, and promises to publish further reports of results.

#### THE QUESTION OF THE COMMITMENT OF THE INSANE.

At the recent meeting of the Congress of Alienists and Neurologists of France, a report of which appears in the *Presse médicale* for August 1st, M. Garnier read a paper on this subject in which he enumerated the conditions requiring the confinement of the insane as follows: The two forms, elementary, or primary, mania and melancholia are the first which demand early confinement, especially in acute cases, in which the patients are sometimes very demonstrative. In these cases the family should be informed, and the possibility of a rapid improvement mentioned if the patient is sent to an asylum.

Melancholia, in its most masked forms, is perhaps the mental disease for which the expediency of confinement is most uncertain; it requires much tact and experience. According to the opinion of the majority of clinicians, lypemania of slight intensity may be cured without confinement in an asylum.

General paralysis is distinguished rather by dementia than by delirium; that is to say, rather by the annihilation of the mental activity than by its deviation; it is not rare, either, to meet with general paralysis in which there is no delirium. It is possible that such patients may be cared for outside of an insane asylum; however, during the early period of the disease there may be a true maniacal excitation which leads to acts of violence and demands the patient's confinement in an asylum.

Senile dementia and mental weakness due to limited cerebral lesions are a cause of much embarrassment.

There is nothing, it may almost be said, to be done for this class of patients. There should be in large cities an establishment somewhat like a hospital in which patients of this class may be placed immediately, an institution which does not come under the regulations that apply to the insane.

Persons with delusions of persecution, whether they belong to the distinctly defined or limited type of chronic delirium or progressive systematic psychosis; whether they betray, by the nature and the method of evolution of their delirious conceptions, hereditary degeneration, are those for whom confinement is particularly urgent.

There are persons who ask to be confined in an asylum, and they are generally those in whom the disease is hereditary or degenerates tormented with a fixed idea urging them to suicide or homicide, and very frequently it is advisable to comply with such demands.

A rather complex question is that concerning the assistance and the confinement of epileptics. Strictly speaking, the latter applies only to insane epileptics, while the former is due to poor patients who are suffering with simple epilepsy only.

Hysteria, with its varied aspects, its protean course, its exceedingly sudden changes, and its exacerbations, gives rise to the greatest difficulties in regard to the expediency of confinement. One fact is certainly recognized, and that is that there is no greater obstacle to recovery in this disease than living at home. If hysteria is accompanied by mental troubles that may be included in the term hysterical mania, if there are cerebral disorders and hallucinations, in which condition the suicidal and even homicidal impulse is not rare, confinement is indicated. However, this sensorial delirium is very often connected with a convulsive paroxysm, and in such cases it is advisable not to be too hasty. This paroxysmal mania is generally of short duration, and at the end of two or three days the storm becomes calmed. As regards hysterical persons whose entire existence is passed on the border line of insanity, who are neither sane nor yet insane, very frequently it is expedient to refuse them a commitment.

The increasing number of degenerates, of feeble-minded, of imbeciles, and of idiots have become a source of embarrassment and great annoyance. They are confined not only for their feeble-mindedness, but especially when a maniacal attack occurs, when there are epileptic attacks, sensorial troubles, etc. When these symptoms have disappeared, the patients leave only to return again after a comparatively short time.

Analogous remarks may be made in regard to alcoholic subjects. Alcoholic delirium is the most frequent

form of mania. A person suffering from acute alcoholism presents the most dangerous form of insanity from the first appearance of the sensorial troubles, and confinement in such cases is advised. But it is of short duration, for the symptoms disappear rapidly at the end of a few weeks.

It may be seen that the term dangerous as applied to different classes of insane persons is not sufficient to determine exactly which patients should be confined to the exclusion of others, although, on the one hand, it can not be affirmed that an insane person reputed to be inoffensive may not become dangerous at any moment, and, on the other hand, it is a duty for the hospitals to render assistance to the poor insane who need special care.

### MINOR PARAGRAPHS.

#### THE NEW YORK STATE QUARANTINE SERVICE.

THE State of New York, and consequently the people of the whole country, are fortunate in having so alert a man as Dr. Doty for health officer of the port of New York. The recent exhibition of improved appliances for the sanitation of infected ships and Dr. Doty's efforts to secure co-operative work in Havana, comparatively fruitless as they are understood to have proved for the present, sufficiently attest the activity of the office.

### ITEMS.

**Infectious Diseases in New York.**—We are indebted to the Sanitary Bureau of the Health Department for the following statement of cases and deaths reported during the two weeks ending August 18, 1896 :

DISEASES.	Week ending Aug. 11		Week ending Aug. 18.	
	Cases.	Deaths.	Cases.	Deaths.
Typhoid fever.....	29	10	56	11
Scarlet fever.....	42	3	11	2
Cerebro-spinal meningitis....	1	1	0	0
Measles.....	77	6	47	6
Diphtheria.....	138	36	97	15
Tuberculosis.....	177	84	103	122

**The Mississippi Valley Medical Association.**—Arrangements have been made with the railroads for reduced rates from New York to St. Paul and return, the rate being fixed at one fare and a third, which will make the cost of the trip, by the New York Central, or the Pennsylvania Railroad, \$42, by the West Shore Railroad, \$38, and by the Erie Railroad, \$39. Tickets should be purchased *via* the Chicago, Milwaukee, and St. Paul Railroad, that being the route selected by a party of the members which will meet in Chicago on September 14th.

**A Good Showing for the Barnes Medical College.**—By some flaw or omission in the return of preliminary qualification of the Barnes Medical College, of St. Louis, to the Missouri State Board of Health, the unprecedented number of a hundred and one matriculates were notified to appear before the board to show cause why they should not be debarred from matriculation, all of whom, responding to the summons, after a rigid personal examination and searching scrutiny of their credentials, were found by the board to be fully qualified by first-grade teacher's certificate or academic or high-school degree, many of them showing ex-

ceptionally high qualifications. This is exceedingly gratifying to the friends of higher preliminary qualifications and to the many friends of the college, and shows that this well-known school at least is not disposed to "let down the bars" to mediocrity for the sake of getting students, as was unjustly intimated and published at the time in this and other journals. We cheerfully record this commendatory statement of fact and wish the Barnes Medical College the continued success it justly merits.

**Army Intelligence.**—*Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from August 9 to August 15, 1896 :*

EWEN, CLARENCE, Major and Surgeon. The extension of leave of absence granted on account of disability is further extended one month on account of disability.

BROOKE, BENJAMIN, First Lieutenant and Assistant Surgeon. So much of Special Order 69, A. G. O., March 23, 1896, as directs him to report to the president of the examining board, appointed to meet at San Francisco, Cal., April 14, 1896, for examination by the board, is revoked.

SHAW, HENRY A., First Lieutenant and Assistant Surgeon, will proceed to Fort Brady, Michigan, without delay, and report for temporary duty at that post.

WOODHULL, ALFRED A., Lieutenant Colonel and Deputy Surgeon General, and SMART, CHARLES, Major and Surgeon, are detailed to represent the Medical Department of the Army at the twenty-fourth annual meeting of the American Public Health Association, to be held at Buffalo, N. Y., September 15, 1896.

**Naval Intelligence.**—*Official List of Changes in the Medical Corps of the United States Navy for the Week ending August 15, 1896 :*

JOHNSON, M. K., Assistant Surgeon. Detached from the U. S. Steamer New York and ordered to the Coast Survey Steamer Bache.

LUNG, G. A., Passed Assistant Surgeon. Ordered to the Receiving-ship Vermont.

STITT, E. R., Passed Assistant Surgeon. Detached from the Receiving-ship Vermont and ordered home on waiting orders.

### Births, Marriages, and Deaths.

#### Died.

CHAFFEE.—In Springfield, Massachusetts, on Saturday, August 8th, Dr. Calvin C. Chaffee, aged eighty-five years.

SHRADER.—In Columbia, Missouri, on Thursday, August 13th, Dr. William Shrader.

WORTHINGTON.—In Louisville, Kentucky, on Tuesday, August 11th, Dr. James Cheston Worthington, of the United States Army.

### Proceedings of Societies.

#### SOCIETY OF ALUMNI OF BELLEVUE HOSPITAL.

*Meeting of May 6, 1896.*

The President, Dr. PARKER SYMS, in the Chair.

**Traumatic Rupture of the Spleen; Operation; Recovery.**—Dr. SAMUEL PIERSON, of Stamford (through Dr. J. Blair Gibbs) presented a report of such a case.

The patient, a boy of ten years, had been seen in con-

sultation with Dr. Treadway on the morning of January 16, 1896. While coasting on the previous evening, the boy had been thrown from his sled against a post and had struck upon his head and shoulder, and had then fallen on his side. When seen by his physician a few minutes later, he had been pulseless, but conscious, and had located his worst pain under the left axilla in a line with the nipple. After careful examination no evidence of fracture of the ribs or of any other injury could be discovered. During the night the boy had vomited almost constantly. When first seen by Dr. Pierson in the morning he had been lying with his knees drawn up, the face pinched, the abdomen very much distended and exquisitely tender. Pulse, 145; temperature, 103.5°; respiration, 40. It was apparent that the boy had sustained some serious abdominal injury, and his removal to the hospital for possible operation had been advised. On arrival there he had been given an enema of warm water which had relieved the distention and tenderness to a considerable degree. Temperature, 102.5°; pulse, 130; respiration, 30. Had the boy been seen for the first time in this condition he would probably not have been operated upon, but having fortunately been under observation from the first, there could be no doubt that he had sustained a serious injury. At six o'clock, twenty hours after the injury had been received, an operation had been done, with the assistance of Dr. Parker Syms, of New York (to whose valuable advice the success of the operation was largely due), Dr. L. R. Hurlbutt, Dr. A. M. Hurlbutt, Dr. Sherrill, and Dr. Gibbs. A small incision had been made in the median line below the umbilicus. When the peritonæum had been reached, liquid blood had been plainly seen underneath, and on cutting through the membrane the blood had gushed forth in large quantity. The opening had been enlarged, and the cavity deluged with a saline solution. Besides the liquid blood a large quantity of clots had been washed out from among the coils of intestines, which had been carefully searched for rupture. As no rupture had been found, and as the fresh blood had seemed to come from the upper part of the abdomen, the incision had been enlarged upward almost to the ensiform cartilage. The liver had been first examined carefully, with a negative result. More clots and liquid blood had been found covering the intestines on the left side under the border of the ribs. After these had been washed away, the ribs had been held up by an assistant, and on depressing the intestines, the bleeding point had been plainly seen in a transverse laceration of the hilum of the spleen. Fresh blood had been oozing from the rent. As it had been impossible, owing to the depth of the cavity and the nature of the tissue, to ligate the bleeding point, a long piece of iodoform gauze had been packed tightly in the rent, and brought out of the upper end of the abdominal wound. The abdominal cavity had been filled with saline solution and the wound closed with silkworm-gut sutures. Profound shock had followed the operation, and three high saline enemata had been given during the night with very happy results. At midnight the pulse had been 148, temperature 102.5°, respiration 26. Oozing had been free during the night, but the general condition had improved steadily. On January 17th, A. M. temperature, 102°; pulse, 130; respiration, 28; P. M. temperature, 101°; pulse, 120. He had passed a fair day, and had retained some milk and limewater. The bowels had been moved freely by calomel on the 18th. For the next three days the temperature had ranged from 101° to 103°, and the pulse from 96 to 120.

On January 21st, five days after the operation, the wound had been dressed under chloroform. The gauze had been removed with some difficulty, and replaced with a much smaller packing. There had been no hæmorrhage. Notwithstanding the absence of suppuration at the first dressing, for the next four days the temperature and pulse had still ranged high. On January 25th several stitch abscesses had been opened, and the cause of the disturbance was thought to have been reached. The next day the temperature had been higher than ever, and a careful examination of the chest had shown fluid in the lower part, and a beginning broncho-pneumonia in the middle lobe of the left lung. The discharge from the wound had nearly ceased and, except for the stitch abscesses, the wound had been entirely healed. For the next five days the temperature had ranged from 100° to 104.5°; pulse from 100 to 130; respiration from 28 to 45. The pneumonia had then begun to resolve, but the fluid had increased, and there had been great tenderness and a fullness over the seat of the laceration in the spleen. The wound had been discharging a moderate amount of serous fluid daily. Fearing that the fluid in the chest might have become purulent, on February 2d an aspirating needle had been inserted and a drachm of pure blood withdrawn. This would, of course, not account for the temperature, and a purulent collection at the seat of the original injury had been feared. At three o'clock of the same day about a pint of thin, chocolate-colored, absolutely non-odorous fluid had been discharged from the original opening. The temperature had immediately dropped to normal, where it had remained until February 13th, when it had again reached 100° without any apparent cause. From this time convalescence had been uneventful, by March 1st the fluid in the chest had been entirely absorbed, and, with the exception of a small sinus, the boy had been entirely well.

So far as he had been able to find, there was no recorded history of such an injury to the spleen, treated by packing only for the stoppage of hæmorrhage. In this case the child's condition had been so bad that no time could be taken in attempts at suturing the rent or in removing the organ. The hæmothorax had evidently been due to the original injury. That the injury would have been fatal without operation, even had the bleeding ceased, seemed hardly open to question, owing to the very large quantity of blood and clots in the abdominal cavity.

Dr. ROBERT T. MORRIS said that, assuming that the patient's bad condition had been due to loss of blood, it would seem to him that the case might have been easily and successfully treated by first giving a large intravenous saline infusion, and then extirpating the spleen, but one must know particulars of any given case.

Dr. J. BLAIR GIBBS said that when the case had been first seen, the patient's condition had been very serious, and the symptoms only those of grave shock. On making an exploratory incision the whole abdominal cavity had been found filled with clots and bloody serum. The removal of this large quantity of blood clot had necessarily consumed considerable time, and when this had been accomplished, the boy's condition had been extremely bad. The spleen had been found to be covered with very adherent blood clots, and with a very well-defined laceration on its anterior border. The hæmorrhage had been quickly stopped by packing with iodoform gauze, and therefore it had been assumed that this simple measure would give the patient the best possible

chance for his life. The spleen might have been removed, of course, but it would have in all probability greatly increased the risk of the operation.

Dr. J. F. ERDMANN said that in this connection he desired to exhibit a spleen in which there was a gunshot wound. He had intended to remove the spleen in this case, but finding the man's condition very bad owing to five perforations of the ileum and jejunum and one of the omentum, he had finally decided to simply pack the wound with gauze. This had been done, and with the very best results, but six days after the operation the man had died from acute uræmia.

Dr. E. LE FEVRE asked if the fluid in the pleural cavity was thought to have been due to the original injury.

The PRESIDENT said that he had only seen the patient once after the operation, the next day, and that then there had been no indication of such a condition. His own impression was that the fluid had been retained blood, of the nature of a subphrenic abscess. He would doubt very much the wisdom of treating most cases of hæmorrhage from the spleen by this method, although it was undoubtedly a very proper procedure in this particular instance. In most cases of rupture of the spleen there was some penetrating wound of the abdomen, or else the spleen had been previously diseased—e. g., from malarial infection. In one case which he recalled there had been a similar rent in such a diseased spleen. The spleen had been sutured, but the patient had died of concealed hæmorrhage, due to a rent which had been overlooked in another portion of the organ. As a rule, the spleen ruptured on the posterior surface from the doubling up of the organ.

**A Roentgen Picture of a Bullet in a Hand.**—The PRESIDENT presented a picture of this kind, taken from a young man who had received a wound in the palm of the hand from a .22-calibre pistol. The speaker said that he had seen the case first on the tenth day after the injury. The wound had been previously probed and an incision made along the fifth metacarpal bone on the supposition that the bullet was there. The Roentgen picture had located the bullet, yet even when the incision had been made between the metacarpal bones it had been impossible to feel the bullet with the finger pressed deeply into the wound. He certainly would not have continued the operation to the point of the removal of the bullet if the picture had not made it entirely certain that the bullet was there.

Dr. ROBERT T. MORRIS presented a Roentgen picture from a similar case. A number of shot had been discharged into the hand, and these had been located with the help of Professor Pupin, by means of an X-ray photograph. Without this aid it would have been absolutely impossible to locate the most important of these shot—namely, those which involved the joints. He was now engaged in removing the shot from the joints. Incidentally, the speaker said he desired to say that he thought the best word for the X-ray photograph was "scotograph." He did not believe in "mule words"—half English and half Greek. The word "scotograph" was of pure blood, and of good descriptive character.

Dr. GIBBS said that he had witnessed the operation in the case described by Dr. Syms, and had been much impressed with the clearness and exactitude with which the bullet had been located. Of course the cellular planes in the hand did not show in the picture, and one might dissect to one side of the bullet.

**Removal of Infected Ligatures.**—Dr. C. C. BARROWS reported the following case: A woman, thirty years of age, had been operated upon by another surgeon eighteen months before, and the appendages had been removed. Since this operation there had been an open sinus at the lower angle of the wound. On April 23d he had carefully dissected out the sinus, and had found a heavy silk ligature at the bottom of it. The sinus had been surrounded by adherent intestine and omentum. The ligature on the opposite side had been entirely absorbed. The specimen was of interest as illustrating how dense and thick the wall of such sinuses might become after a time.

Dr. A. BROTHERS presented two ligatures which had been placed in the peritoneal cavity last January during a double salpingo-oophorectomy. The operation had been done *per vaginam*, and the pedicle had been tied with silk. The patient had been discharged in less than three weeks, cured, with the exception of a small vaginal sinus. On April 4th, nine weeks after the operation, she had returned complaining of vague pelvic discomfort, and on examination one of the ligatures had been felt protruding, and had been removed. The wound had failed to heal, and to-day he had removed a second ligature. The advantages of the vaginal method were well shown in this case, because in the event of the ligatures becoming infected a natural outlet was provided. Some years ago he had seen a similar case, in which a distinguished gynæcologist of New York had operated. The sinus had remained open for nearly six months, and had only healed after the spontaneous discharge of an infected ligature.

**A Needle in the Omentum.**—Dr. J. F. ERDMANN exhibited a piece of omentum in which was imbedded a darning needle. It had been found in a dissecting-room subject apparently about fifty-three years of age. There were no adhesions except those bands which had held the needle in place in the omentum.

**Foreign Body in the Œsophagus.**—Dr. A. BROTHERS said that a few evenings before a man had come into his office suffering extreme distress. He had stated that while he was eating, something had become lodged in the gullet. An olive-shaped bougie had apparently passed into the stomach with but little resistance, but on a second attempt a large piece of gristle had been dislodged, and had been discharged after withdrawing the bougie. If this body had happened to become fixed higher up, it might have caused death by pressure on the larynx.

**Treatment of Chronic Disease of the Ankle and Tar-sus.**—Dr. W. R. TOWNSEND read a paper with this title (see page 256), and presented the following case in illustration: The patient, a boy of three years, had been brought to the Hospital for the Ruptured and Crippled with chronic ankle-joint disease, and the Thomas brace described in the paper had been applied. The speaker said that the change of contour, the prominence of the veins, the atrophy of the limb, and the limitation of motion at the tibio-tarsal articulation had been sufficient to stamp the case as one of chronic ankle-joint disease.

Dr. LE FEVRE asked if some lighter metal could be used for the brace, such as aluminum.

Dr. TOWNSEND replied that he had tried aluminum, but so far it had not been successful, probably owing to lack of experience with the working of it by the instrument makers. With a suspender over the shoulder the patient never experienced any discomfort from the weight of the brace. Of course the uprights could be made of hollow tubing.

*Meeting of June 3, 1896.*

The President, Dr. PARKER SYMS, in the Chair.

**Hydrosalpinx and Ovarian Cyst removed Per Vaginum without Removal of the Uterus.**—Dr. C. C. BARROWS presented two specimens of this kind. He said that of course it was easy enough to remove these if the uterus was also extirpated, but otherwise it was sometimes rather difficult of execution. He had not taken out the uterus because the other tube and ovary had been brought down and examined, and found in such good condition that extirpation did not seem to be warranted. Both women had recovered rapidly and completely.

**Hysterectomy, with Special Reference to the Technics by the Vaginal Route.**—Dr. FREDERICK HOLME WIGGÉN read a paper with this title (see page 258), and also reported a successful case of intestinal anastomosis by the Maunsell method.

Dr. G. W. JARMAN said regarding Mackenrodt's incision that it did not seem to him that the linear incision would ever become very popular for the removal of the uterus. In certain cases there was so little connective tissue between the vagina and bladder that it was almost impossible to make the incision without injuring the bladder. What seemed to him much better was the incision described recently by Sagond—a perfectly circular incision around the cervix, and then one on either side up to the fornices. This gave a great deal of room. He had only made the Mackenrodt linear incision once, but he did not feel disposed to repeat it. He was of the opinion that in extirpation of the uterus for non-malignant disease better conservative surgery could be done through the abdomen than through the vagina. There were certain cases where it was almost impossible to remove an adherent tube and ovary through the vagina. When operating from above, it was comparatively easy to examine the parts, and if they were injured in so doing they could be at once removed. In cases of malignant disease he favored the vaginal method in order to avoid the exposure of the peritoneal cavity. He did not think any part of vaginal hysterectomy would render so much care necessary on the part of the surgeon as the combined operation, for after working in the vagina the hands were almost certain to infect the patient. If after vaginal work one were forced to enter the abdomen, one must make special preparation before making the abdominal incision. The closing of the cervix by ligature or suture seemed to him entirely unnecessary. It consumed considerable time, and the same object could be much more easily and quickly accomplished by grasping the uterus with a double volsella forceps. Personally, he had not found any advantage from closing the vagina after vaginal hysterectomy. This also introduced an element of time without a corresponding gain. Of course, if one was not sure of the perfection of one's aseptic technics, it would be better not to do it. It was advisable to introduce a broad handkerchief of gauze into the vagina, and then to fill this in with small pieces of gauze—the ordinary Mikulicz drain. An exudation of plastic lymph very soon formed over the gauze and shut off the peritoneal cavity. He agreed with the reader of the paper that where ligatures could be used they were desirable, but there were cases in which they could not be used, as, for example, where the tissues were quite friable. In one instance, some years ago, he had carefully removed the clamps at the end of fifty hours, and had been surprised at the occurrence of a very profuse hemorrhage, which could only be controlled by abdomi-

nal section and the application of a ligature to the bleeding vessel. In view of this experience, he would advise against removing the clamps for at least sixty hours. He was convinced that he had seen one patient die from the giving of douches too soon after a vaginal hysterectomy. Where gauze had been put into the vagina, the adhesions would be slight, and one would be apt to break up these adhesions by the premature use of a douche. There was certain to be septic material after a vaginal hysterectomy, and such a douche was almost sure to force in some of this septic material. He would much prefer swabbing out the vagina with cotton moistened with some antiseptic solution. He was convinced that recovery was more satisfactory if the gauze was allowed to remain undisturbed in the vagina for from five to seven days. Removal of the gauze from the vagina was usually painful, but if it was gradually taken out it could be done with little or no discomfort to the patient. Regarding abdominal hysterectomy, he would say that he did not believe that the cervix added anything to the strength of the pelvic floor. Two cases of carcinoma of the cervix had been reported after abdominal hysterectomy for other purposes, the cervix having been left behind. This was, of course, a remote possibility, but still should be borne in mind. The most important objection to leaving in the cervix was the defective drainage thereby produced.

The speaker then referred to a patient with hemorrhagic endometritis who had been previously curetted twice by a competent physician before he had seen her. The woman had been almost exsanguinated, but at the suggestion of her physician he had also tried the curette. The products of the curetting had been examined and no malignant growth reported. The hemorrhage had recurred after the curetting. He had then removed the uterus, and referred it to the pathologist of the hospital, and had also submitted portions to two other pathologists for examination. All the pathologists had reported that there was nothing abnormal except a very small mural fibroid. Fourteen months later the woman had returned with a carcinoma. He had seen her within a few days, and the pelvis had been filled with carcinomatous tissue. This case had discouraged him greatly from doing a vaginal hysterectomy for cancer, for in every way it had seemed to be a hopeful one for operation. He felt that some patients with hemorrhagic endometritis would bleed in spite of curettage, and that these required hysterectomy.

Dr. BARROWS said that he had been particularly interested in the technics, as described in the paper of the evening. His views were very similar to those expressed by the last speaker. He had had an opportunity to see a good deal of the technics of Dr. Segond, and had been charmed with his manner of operating. Not only had he been impressed with the incisions already described, but with his division of the uterus through the median line. Segond first curetted the uterus and cervix very thoroughly with a sharp curette, and washed out the parts with sterilized water. He next divided the uterus on its posterior face up to the fundus, having first placed clamps on the uterine arteries on either side. Having reached the fundus, he slipped his finger down behind the uterus and incised the posterior wall on his finger. The uterus was then in two halves. Attached to each half was one broad ligament and an appendage. This could be used as a handle to aid him in enucleating the appendages, and it gave him complete control of the broad ligaments. It was well known that in the old

method of operating there was sometimes much difficulty experienced in controlling the bleeding from adhesions high up, for fear of displacing the clamps and ligatures. Of course, it was very necessary to make the uterus as nearly sterile as possible before beginning this operation. He was also in accord with Dr. Jarman regarding conservative work, believing that the abdominal route was the correct one for such work. In the cases reported this evening with specimens, the operation had not been intended originally for conservative work, but the cases had proved to be of this class. Regarding the question of operation upon malignant disease, he thought it was best to operate from above by Dr. Polk's recent method. The uterus and vagina having been packed with iodoform gauze, the abdomen should be opened, the ovarian vessels and round ligament ligated, and then the folds of the broad ligament opened and followed out to the pelvic wall. The anterior branch of the internal iliac artery should then be picked up and ligated. This could be very easily accomplished, especially in cases in which the uterus was not very large. The method was particularly adapted to carcinoma. This method gave a practically bloodless field. The operator could thus remove enlarged glands or suspicious tissue as easily as from the axilla in a case of amputation of the breast. Probably half or more of the vagina could be dissected out, if necessary, before any bleeding would be met with. He believed this would be found a very great improvement over the usual method of operating for carcinoma. He had done a good many vaginal operations for carcinoma, and as a rule they had not been very satisfactory as regarded recurrence. He would in the future adopt the method just described.

Dr. BARROWS said he could see no reason for leaving any part of the cervix in cases of disease of annexa or of fibroids. It was certainly a menace to the woman, and there was no advantage in it. He had operated in one case because of the annoying discharge which had issued from this cervix, and had caused much discomfort. The question of clamps or ligatures depended upon the individual preference of the operator and the peculiarities of each case. Personally, he preferred clamps.

Dr. HENRY C. COE said that he thought those who had seen Segond operate would admit that he gained a great deal of room by the use of the circular, combined with the vertical incisions. With reference to the recurrence of carcinoma after vaginal hysterectomy, he would say that he had become a pessimist regarding all so-called radical operations for malignant disease of the uterus. The operation was hardly comparable to the radical operation for disease of the breast, because the conditions were very different. The bloodlessness of the operation referred to by Dr. Barrows was, of course, a great advantage, but the possibility of removing all the affected tissues seemed to him very problematical. The operation appeared to be a severe one, which one would hesitate to attempt in private practice. Regarding clamps and ligatures, he said that he had used clamps in a large number of cases. They had been tried quite extensively in the Cancer Hospital as far back as 1886, but the results had been so bad that they had been abandoned until recently. The great objection to the clamp operation was the extensive sloughing process. He had been surprised that we had not lost more patients from this cause; certainly it could hardly fail to impress one as an unsurgical method.

Any one who had seen Dr. Kelly operate must have

been impressed with his wonderful dexterity. He had seen him remove an ordinary fibroid tumor in five minutes, though he occupied twenty minutes or more in suturing the stump and closing the abdominal wound. After all, then, there was not much gain in time by his operation. He could see no advantage from the retention of the cervix. He had never met with a vaginal hernia after complete extirpation, and Segond had stated that he had never seen the condition in a series of six hundred cases. Certainly the cervix might give trouble afterward; he had known it in a few instances to undergo carcinomatous degeneration.

Dr. W. EVELYN PORTER said regarding the indications for hysterectomy that it seemed to him that the operation was performed very frequently where the simpler method of enucleation of fibroid growths would be more apt to result favorably for the patient. As to doing the operation for hæmorrhagic endometritis, he said that occasionally one met with cases in which every means failed, including ligation of the uterine vessels and removal of the appendages. He would favor a trial of other surgical means, however, before resorting to hysterectomy, even in these severe cases. As to the technique of the abdominal operation, he always preferred to remove the entire uterus, but in some cases where the stump was large, and there was difficulty in bringing it up into the wound, it might be wise to leave the cervix. The vertical incision would undoubtedly furnish much aid in operating through the vagina, for it gave a better view of the vessels. He believed that clamps should only be used where ligatures could not be applied. After vaginal operations he preferred to close up a considerable part of the vaginal roof, instead of leaving it open and packing it. It was his habit to unite the surfaces posteriorly to avoid the bleeding from the vaginal artery. He only left a small opening in the roof for the purpose of drainage. This seemed to him an important part of the technique.

Dr. WIGGIN said regarding the separation of the bladder from the uterus, that he had never found any difficulty in doing it, although he had performed it quite a number of times. The passing of a sound into the bladder enabled one to estimate the thickness of the wall, and if the transverse incision was made with the edge of the knife toward the cervix, there was no danger of wounding the bladder, or difficulty in stripping it off from the uterus with the fingers. He had found the Mackenrodt incision so useful in the operation for retrodisplacements that he had applied it to hysterectomy, as had also Dr. Vineberg. The great point was the dissection of the flaps laterally. If this was properly done, a large field was exposed for operation, and there was very little difficulty in securing the arteries and ligaments. He understood that the leaving of the stump in Kelly's method was done chiefly with the idea of shortening the time of operation. In cases in which there was no malignant disease, it certainly seemed to be a very rapid method.

---

## Miscellany.

---

**The American Association for the Advancement of Science.**—The forty-fifth annual meeting will be held in Buffalo on August 24th, 25th, 26th, 27th, 28th, and 29th. The preliminary programme includes the follow-

ing titles: The Determination of Osmotic Pressure from Vapor Pressure Measurements, by Dr. A. A. Noyes and Dr. G. C. Abbott, of Boston; Distillation with Vapor, by Professor W. D. Bancroft, of Ithaca; A Physico-chemical Study of Water Solutions of Some of the Alums, by Dr. H. C. Jones, of Baltimore; The Hydrolysis of Ferric Chloride, by Professor H. M. Goodwin, of Boston; The Viscosity of Mercury Vapor, by Dr. A. A. Noyes and Professor H. M. Goodwin, of Boston; Some Points in Nomenclature with Regard to Analysis of Mineral Water, by Professor F. W. Clarke, of Washington, D. C.; The Alkali Trihalides, by Professor C. H. Herty and Professor H. V. Bloch, of Augusta, Ga.; The Action of Copper upon Sulphuric Acid, by Professor Charles Baskerville, of Raleigh, N. C.; A Bibliography of the Metals of the Platinum Group, by Dr. James L. Howe, of Lexington, Va.; A Review of the Atomic Weight of Magnesium, by Professor J. W. Richards and Professor H. G. Parker, of Cambridge, Mass.; Organic Chemistry, by Professor Paul C. Freer, of Ann Arbor, Mich.; The Hydrazones of Quinones, by Professor William McPherson, of Cincinnati; Camphoric Acid, by Professor W. A. Noyes, of Terre Haute, Ind.; Some Points in Teaching Technical Chemistry, by Professor J. H. Norton, of Cincinnati; The Aim of Qualitative Analysis, by Dr. G. C. Caldwell, of Ithaca, N. Y.; How Far shall we Use the Periodic Law in Teaching General Chemistry? by Dr. F. P. Venable, of Chapel Hill, North Carolina; Chemistry at the Rensselaer Polytechnic Institute, by Professor W. P. **The Influence of Deafness upon the Development of the Child.**—The August number of the *Laryngoscope* contains an article by Dr. H. A. Alderton, of Brooklyn, who remarks that impairment of the hearing must influence disadvantageously the development of the child primarily in two ways: First, by curtailment of the field of observation; second, by limitation of the possibility of instruction, and these limitations reacting upon each other both adversely influence the child. The first impression given by a deaf child is one of inattention. It is regarded as being somewhat dull and absent-minded, and imperceptibly people get into the habit of speaking sharply in order to attract the child's attention. It is often reproved for not paying attention to what is said to it or for not doing things it has been told to do. The child gradually begins to appreciate the feelings it inspires, and this tends still further to limit its receptivity by rendering it sensitive and fearful of ridicule and harshness. The too frequent use of the latter, says Dr. Alderton, breeds a carelessness of reproof and of desire on the part of the child, who too often feels itself the victim of thoughtless injustice. At school the child becomes inattentive, loses instruction, and does not progress. It falls behind in its studies and appears to be dull and slow, and the teacher's efforts to instruct become more and more perfunctory and valueless. The child loses

interest and is, as a natural consequence, led to spend its mental and physical energies in ways that are forbidden. At play it is the same thing, and the child gradually loses interest and follows pursuits which do not require the co-operation of others. As it lacks thus the incentive to exercise which comes from companionship and the attendant competition and collaboration, malassimilation and malnutrition increasingly make inroads upon the system in general.

Unfortunately, says Dr. Alderton, by the time that parents are willing to admit that it is deafness and not dullness that is the trouble, they have got into the habit of regarding the child as stupid, inattentive, and insubordinate. The case progresses so gradually that the damage is done before they are aware of it, and regrets and recriminations are useless.

The effect of these various influences upon the development of the child, says Dr. Alderton, is unfortunate in the extreme. The mind, deprived of its customary cultivation, ceases to expand in proportion to the growth of the individual; the child is backward. The disposition, constantly disturbed by contempt, ridicule, harshness, or overconsideration, becomes uncertain and unreliable, sensitive, and uncontrollable. The bodily health, by want of fresh air and exercise, mental worry, and disturbance, becomes impaired; the osseous, muscular, vascular, respiratory, and nervous systems all feel the effects of malassimilation and malnutrition—especially when the deafness, as it so often is in childhood, is combined with or due to the development of adenoid growths in the nasopharynx. All these influences, combined, result in producing the narrow-chested, small-boned, feeble-muscled, and mentally inactive specimen so frequently seen in the dispensary clinics. When the sphere of prophylaxis in these cases is considered, the criminality of the negligence which allows of such results becomes more and more apparent.

Dr. Alderton thinks there should be periodical compulsory examinations of school children for the discovery of all such defects as poor eyesight and difficulty of hearing. The parents of children found to be hard of hearing should be immediately notified of the fact and strongly recommended to place them under the care of a competent aurist, either privately or at one of the numerous public institutions. No child need go neglected. As ineffectual treatment is often worse than no treatment, communication should be had with the family physician, recommending that the child be at least examined, if not treated, by a competent specialist.

Coincidentally, he thinks, it should be the duty of the local board of education to form a special class in the public schools for the instruction of these handicapped children by teachers trained especially for this purpose. It is not a matter to be left to private enterprise and charitable institutional methods. The child with impaired faculties is as much entitled to public instruction as the healthy child; the fact that unusual methods and special teachers are required should be no rightful bar to its claim. Let these things come to pass, he says, and the reproach of preventable deafness would pass from us with all its attendant expense to the body politic.

**Itching and its Treatment with Large Doses of Calcium Chloride.**—In the *Lancet* for August 1st Dr. Thomas D. Savill remarks that the frequency and troublesome nature of this symptom make the subject of pruritus or itching one of considerable importance. It is a subjective symptom which may take varied forms in

different individuals and is variously described by them as tingling, smarting, burning, throbbing, creeping (as of insects), and flickering along the course of vessels and nerves, all of which, he says, are included when he uses the term pruritus or itching. Pruritus, or itching, must not be confounded with prurigo, which is pruritus with an eruption which has well-defined characters. The use of the adjective pruriginous as synonymous with itching is not justifiable and leads to confusion.

Etiolegically considered, says the author, pruritus, or rather the peripheral nerve irritation on which it depends, may be *primary*, when no eruption is present or when it only appears secondarily, or *secondary*, where the itching accompanies or succeeds some manifest eruption on the skin.

Illustrations of *primary pruritus*—that is, a condition where itching is the principal and often the only symptom referable to the skin—may be found in jaundice and diabetes; in the pruritus so frequently attacking the aged; in the itching after the hypodermic injection of morphine in large doses, and other drugs directly into the lymph or blood current; the pruritus which follows eating unwholesome food, and especially shell-fish or tinned meats—the itching in such circumstances being often attended by an urticarial eruption, though sometimes pruritus alone is present; and he believes that an illustration of primary pruritus is also found in the disease variously called prurigo, lichen urticatus, urticaria papulosa, etc., which, in his opinion, are names applied to the same disease varied by circumstances.

The pathological explanation of primary itching is not so easy as that of the secondary variety. The question before us, he says, is, What is the pathological change which produces this irritation of the sensory nerve endings or fibrils? It may, in the first place, be remarked that it is hardly likely to be an actual disease of the sensory nerve endings or fibrils—a neuritis—else there would be more frequently symptoms referable to peripheral neuritis, where none such occur; the symptom of itching would not vary, and even disappear, from hour to hour as it often does. What, then, he asks, is the condition which, while it irritates, does not cause definite disease of these structures? Some say an abnormal dryness of the skin—an anidrosis—is the cause of the nerve irritation; but although this dryness exists in some cases of pruritus, notably the itching of diabetes, it is very far from being a constant feature. Moreover, it does not follow that because the surface of the skin is dry the nerve endings in the deeper layers of the epidermis are also dry. It is known, too, that secretion is regulated by nerve influence, so that diminished secretion is rather an effect than a cause of the nerve irritation, or it may be in some cases that they are both the effects of a common cause. Even in the pruritus of cold weather (pruritus hiemalis), which is pointed to in support of this theory, a readier explanation is found of the nerve irritation in the retention in the blood of products which ought to be eliminated by the skin than in the excessive dryness.

This secondary pruritus is readily explained, says Dr. Savill, by the involvement of the nerve endings and fibrils actually in the skin lesion—congestion or inflammation—or, in the case of parasites, by the irritation of their claws and probosces. This is the simple mechanical explanation. The treatment is equally simple and consists of the removal of the cause. The reason itching is absent in some strumous and syphilitic eruptions is probably either because they are frequently pustular and

thus the sensory terminations are destroyed, or because the inflammation is of an indolent and chronic kind. Nerve structures have a wonderful power of adaptability in this respect. Very slowly growing brain tumors may in this way exist for many years without manifesting their presence. In the Hunterian Museum, he says, there is a fibroma of slow growth (judging by its histological characters) occupying both the arm and leg centres of the right hemisphere without having produced paralysis or other symptoms during life, the patient having died from double pneumonia without the tumor having ever been suspected. It is not, therefore, surprising that the nerve fibrils should not be irritated by slowly growing, indolent skin lesions; and, on the other hand, that the itching and smarting should be very severe when the morbid process is rapid or acute.

As to the efficacy of calcium chloride, says Dr. Savill, in relieving the itching, the patients themselves have no doubt whatever. In all the cases which have come under his observation the itching has been relieved, and the eruption, if any existed, has disappeared at the same time. He states further that he has not met with any absolute failures so far, although sometimes the dose has had to be considerable and continued for several weeks. The opportunity of trying the remedy in children for the itching that accompanies urticaria, he says, has not presented itself, but there is every reason to believe that it would be equally efficacious in them.

With regard to the mode of administration, Dr. Savill says that the doses must be considerable, not less than twenty grains three times a day, and they should be gradually increased. Thirty and even forty grains have often succeeded where smaller doses have failed. If administered after meals and in a wineglass of water it is surprising how little these large doses upset the stomach, and he states that he has never known it produce vomiting. Patients sometimes complain that it makes them thirsty, and to cover the salt taste it is best administered with a drachm of tincture of orange peel and one ounce of chloroform water, in which form it is really an agreeable medicine and would be well taken by children. It is important that the diet at the same time should be regulated, no beer, sugar, or sweets being allowed, and meat only in very moderate quantity. It is also important to keep the bowels acting freely. Although improvement is generally noted after the first dose, complete recovery is sometimes not obtained until the blood becomes saturated, and the dose must be increased until this is accomplished. In long-standing cases perseverance is necessary.

When recovery is obtained the dose should be gradually, not suddenly, reduced, and it is very important that the remedy should be continued for at least from one to three weeks after all symptoms have disappeared.

It is not possible yet, he thinks, to indicate precisely which cases are most suitable for this treatment, but it is worth trying in all cases where itching is a pronounced feature.

In most of the cases an actual cure resulted, but in a few of very long duration relief was obtained only so long as the drug was being taken. Nevertheless, cure will probably result with perseverance even in these.

**Glycerin Poisoning.**—Antichievich (*Archiv für Kinderheilkunde*, xx, 1896; *Fortschritte der Medizin*, August 1, 1896) remarks on the rarity of glycerin poisoning, but adds that it is none the less of importance. It showed itself in the form of acute nephritis in the case

of a boy who was under treatment with injections of a glycerin solution of iodoform, but this disappeared at the end of three weeks of a milk diet. In another case hæmoglobinuria came on after the second injection, and there was polyuria for eight days. Further iodoform injections were well borne after olive oil had been substituted for the glycerin. It is remarkable that such decided phenomena should follow upon the use of comparatively small amounts of glycerin, says the author.

**The Abortive Treatment of Acute Suppurative Adenitis of the Groin by Pressure Bandage.**—The frequency with which the complication of acute suppurative adenitis of the groin is present in cases of urethritis and chancroid, says Dr. A. Bradley Gaither in the July number of the *Johns Hopkins Hospital Bulletin*, and the very unsatisfactory results of treatment instituted to check the process, should make any procedure which holds out even a fair chance of success most welcome. When used for abortive treatment, applications of iodine, mercurial ointment, belladonna ointment, etc., have given practically no results, while injections of solutions of bichloride of mercury or carbolic acid are painful and apt to set up a great deal of inflammation. There is also the risk of infecting the bubo, the contents of which are always absolutely free from germs. In the hands of some operators gratifying results have been obtained from injections, but, as a rule, they have been discarded as unsatisfactory. In fact, all the abortive methods having been found wanting, it has become more and more popular with surgeons to abandon such treatment altogether, and to endeavor to bring the condition to an operative stage as soon as possible.

Dr. Lydston, he says, advocates the early and complete extirpation of all buboes. He maintains that when suppuration has begun in the glands, and this suppuration begins early, even as soon as the third day, the inflammation extends to the circumglandular tissue; and then the case becomes long and obstinate, from the continued suppuration.

Dr. Edward Martin says that in the treatment of bubo the best results in the long run would be obtained by immediate incision of the glands as soon as they become markedly inflamed, and closure of the resulting wound by suture. It is a good rule to attempt the abortion of a bubo not longer than three days. If no good results follow in this time, suppuration will almost certainly occur.

Such, continues Dr. Gaither, was his opinion before using the pressure-bandage abortive treatment, but on account of the results obtained from a series of cases he now advises putting on a pressure bandage, regardless of the age of the bubo, if suppuration has not advanced to such a degree as to bring the case practically to the operative stage.

The bandage is applied as follows: A piece of cotton as large as the fist is folded in on itself again and again until it has the shape of the bubo, and when placed on it does not completely cover it. This is carefully adjusted, and a wad of tightly compressed cotton as large as a cocoanut placed over it. Small pieces of cotton are also used on the inner and outer surfaces of the thigh, to prevent chafing. A very tight spica bandage is then put on.

The amount of pain experienced by the patients varied greatly. In some cases the pressure did not seem to increase it at all. In fact, the relief of pain has been, in most cases, remarkable.

One man with a large bubo in each groin had suffered a great deal and had been unable to work for three weeks previous to applying for treatment. Two days after the double bandage had been applied he returned to his work, that of a laborer, and continued the same without interruption while the buboes were being aborted. In almost every variety of treatment for bubo, the point insisted on is rest in the dorsal decubitus. While the patient is wearing the pressure bandage this is by no means imperative, though it is to be preferred. If the bandage remained in position twenty-four hours, even if the gland went on to suppuration, the pain would be diminished.

In a series of cases which were treated in the genito-urinary clinic of the Johns Hopkins Hospital Dispensary, the bandage was used regardless of the condition of the bubo or the apparent hopelessness of success.

Eighteen patients were treated, four of whom were practically in the operative stage when the bandage was applied, and three of the four showed no improvement.

In two cases the men were unable to keep the bandage on more than a few hours, saying that the pain, already great, became unbearable.

Of the remaining twelve cases, the bubo was aborted in nine, including two which seemed to be so far advanced as to leave no chance of success. The earlier the bandage was applied the better was the termination, and if treatment was begun before any sign of suppuration could be made out, a satisfactory result was obtained in more than eighty-five per cent. of the cases.

In estimating this percentage it must be held in mind that in a certain proportion of cases a bubo will subside while we are doing our best to hasten suppuration. Dr. Gaither refers to the case of a man who had a bubo in each groin, one of which had reached the operative stage, while the other was not quite so far advanced. In order that both might be incised at the same time, he was advised to apply a poultice and come back in three days. He kept poultices continually on each bubo, and on his return it was found that suppuration was being checked on both sides, and eventually he recovered without operative interference.

Dr. Gaither thinks that the following can be said in favor of the pressure-bandage treatment: 1. It is safe. 2. Pain is, as a rule, diminished after twenty-four hours. 3. It does not prevent the patient from pursuing his usual occupation. 4. It gives a high percentage of success.

**The Indigestion of Breast Babies.**—The August number of the *Edinburgh Medical Journal* contains an article by Dr. James Carmichael, who says that, for many reasons, less attention has been paid to the gastro-intestinal affections met with in breast babies than in those nursed artificially. Breast milk is the natural and ought to be the sole food of the infant, under physiological conditions, during the first year of life.

In inquiring into the causes of indigestion in breast babies, it may be assumed that, in a healthy child nursed by a healthy mother, it rarely, if ever, occurs. The conditions which lead to a departure from normal conditions, and which injuriously affect the child, are numerous. A certain group of causes which may affect both mother and child simultaneously are defective hygienic conditions generally, such as unhealthy, low-lying, and damp dwelling houses, noxious effluvia from drains, or malarial poison. Under such circumstances both mother

and child are apt to suffer, unless removed from the injurious influences. As it is to the mother specially that we have to look when the child suffers, any departure from normal health is apt to affect her milk supply.

Whenever the milk of the mother is defective in quantity or quality, the child is apt to suffer. It does not thrive or grow at the normal rate. Instead of being plump and firm and happy, it is soft and flabby, and is always crying, and never appears to be satisfied. Its skin is harsh and dry. The tongue is somewhat red, often slightly furred. Vomiting is not infrequent from gastric catarrh. The stools are unnatural, and present various appearances depending on the quality of the milk. They are generally loose, and seldom have the natural mustard color or consistence; but are usually pale, and often of an ashy gray color, sometimes greenish, or mixed gray and green. The soft curd of the mother's milk is present, undigested, in little granular-looking masses. There is an excess of mucous secretion, sometimes little streaks of blood. As a rule, the indigestion of mother's milk is more frequently intestinal than gastric, diarrhoea being more common than vomiting. This, says the author, appears to be largely due to indigestion of the fatty and proteid elements of the milk. Infants, in regard to their digestive capabilities, are but little men and women, and it is certain they have their idiosyncrasies likewise. The milk of a mother seems to be suited to her own child under physiological conditions. It has been proved over and over again that a child who is thriving on its own mother's milk if put to another may suffer, even although the woman is healthy and her milk is found on analysis to be of good quality. This is one of Nature's mysteries which it is difficult to explain, he says, but yet remains as a fact demonstrated by observation and experiment. It shows how subtle and delicate the nutritional relations are between mother and child. If this is so in natural feeding, it helps to explain the difficulties which are encountered when the child is artificially reared.

With regard to the management of indigestion generally, it is well to ascertain the cause, and look to the mother and her habits. The breasts, the milk, and the evacuations of the child should be carefully examined. In this way a conclusion as to the cause of the indigestion in the greater majority of cases may be reached. If there is any disease, functional or organic, of a persistent nature, the case must be considered in all its bearings, and a decision come to as to the possibility of continuing lactation with any prospect of success.

The occurrence of menstruation requires careful consideration in regard to nursing. Analyses show that during the menstrual period the milk is deteriorated in quality, and gives rise to more or less disturbance, often of a trivial nature, in the child. On the cessation of the menstrual flow there is generally a return to normal conditions as regards the quality of the milk, so that menstruation in most cases is not a bar to nursing. It may come on a few months after lactation has commenced, and not recur for several months, so it is undesirable to wean the baby if it can be avoided on the occurrence of the first menstruation. It is a very different matter when pregnancy occurs. In this case it is necessary and desirable that the child should be weaned.

The diet and regimen of the mother during lactation is of the first importance. It must be borne in mind, continues the author, that the whole process is a physiological one, and that a healthy mother requires really no special treatment during the nursing period. She ought

to take her usual food, a plain and mixed dietary, and have a due amount of open-air exercise. A good nurse generally has an excellent appetite and digestion, and is usually able and ought to eat a somewhat larger quantity of food than at other times, and probably a shorter interval between meals may be advisable. She should have a late meal, and in the early morning some soup, or a glass of milk or cocoa and a biscuit or bread and butter. It is desirable that a mother in good average health should fulfill the maternal duty of nursing her child if possible. Many mothers are too apt to seize the opportunity, if anything is wrong, to give up nursing, and in this they are often influenced by the father, who ought to be out of court in such matters. Medical practitioners are apt in many cases to give in to the wishes of the parents in this respect instead of encouraging the mother to nurse her child, and counseling patience and rational treatment with a view to improve the milk supply. Dr. Ballantyne considers it the physician's duty to encourage mothers to nurse their children if there is no distinct contraindication. Inquiry must be made into the habits and hygienic conditions under which the mother is living. The milk must be examined, and will not fail to give valuable information. If it is deficient generally in quantity, he says, endeavor to inspire hope in the mother that she may yet be able to nurse her child; and if her appetite and digestion are good, advise her to take an increased quantity of the lighter and more quickly digested nutriment, with plenty of liquid. If she has too much milk, the fluids must be reduced and the solids increased. Irregular suckling must be prohibited, as a common cause of indigestion in the infant. If chemical examination of the milk shows increase or diminution of the proteids, fat, or solids generally, prescribe accordingly. To increase the solids, give the child the breast more frequently, prevent the mother from overexerting herself, and do not let her drink too much. To decrease the solids, order longer intervals between the nursings, more exercise, and a larger amount of fluid nutriment. Increase of fat indicates the need of less animal food in the dietary. Diminution of fat requires a larger quantity of animal food. The most certain way of regulating the amount of proteids is by muscular exercise, allowing plenty of exercise if the amount of proteids is too large, and decreasing the amount of exercise if they are deficient.

**Injections of Artificial Serum.**—At a recent meeting of the Société de biologie, a report of which appears in the *Journal des praticiens* for July 25th, M. Bosc and M. Vedel presented the following conclusions: 1. Large intravenous injections of a simple saline solution are not toxic, in spite of their quantity and the rapidity with which they are given—from forty-five to eighty-three cubic centimetres a minute. 2. The physiological effects of these large injections are not in proportion with the temperature of the solution and the rapidity with which the injection is made. 3. These injections produce an abundant diuresis which occurs half an hour after the solution has been injected; there is no elevation of the blood pressure, and no albuminuria; but there is acceleration of the heart and an elevation of the central and peripheral temperature which resembles that of fever. 4. A seven-per-cent. solution of sodium chloride is preferable to a five-per-cent. solution. 5. Large intravenous injections of compound saline solution (chloride and sulphate of sodium) are deprived of their harmful effects under the same conditions as those of the

simple saline solution. 6. There is no difference between the effects of these two solutions. 7. The addition of sodium sulphate to the sodium chloride does not seem to be useful; it seems rather to be prejudicial to globular preservation, according to Mayet. 8. During a series of injections each injection produces the same effects as a single injection; they are also equally harmless. 9. The fasting animals appear to be more susceptible to large intravenous injections, but, in spite of the appearance of grave symptoms during the administration of the injections, even apparent death, the animals rapidly return to their normal condition. 10. The simple saline solution (a hundred and five grains of sodium chloride to thirty ounces of water) seems to be the preferable solution for intravenous injections; it produces the minimum of harmful effects and the maximum of physiological effects.

**The Canadian Medical Association.**—The twenty-ninth annual meeting will be held in Montreal on August 26th, 27th, and 28th, under the presidency of Dr. James Thorburn, of Toronto. Besides the president's address, the programme includes the following papers: An address in bacteriology, by Dr. J. G. Adami, of Montreal; an address in medicine, by Dr. George Wilkins, of Montreal; an address in surgery, by Dr. John Stewart, of Halifax; an address in midwifery, by Dr. J. F. W. Ross, of Toronto; Hæmorrhagic Pancreatitis, by Dr. A. McPhedran, of Toronto; A Hundred Cases of Retroversion of the Uterus treated by Ventrofixation and Alexander's Operation, with Subsequent Results, by Dr. A. Lapthorn Smith, of Montreal; The Influence of Mitral Lesions on the Existence of Pulmonary Tuberculosis, by Dr. J. E. Graham, of Toronto; A Note on Amputation at the Hip Joint in Tuberculous Disease, by Dr. A. Primrose, of Toronto; Tetanus following Scarlatina, by Dr. J. B. McConnell, of Montreal; The Ætiology and Treatment of Acne, by Dr. A. R. Robinson, of New York; The Foot, its Architecture and Clothing, by Dr. B. E. McKenzie, of Toronto; Ophthalmia Neonatorum, by Dr. R. Ferguson, of London, Ontario; Observations on the Relations between Leucæmia and Pseudo-leucæmia, by Dr. C. F. Martin and Dr. G. H. Matthewson, of Montreal; Thyroidectomy, by Dr. D. Marcell, of St. Eustace, Quebec; Some Observations on the Heredity of Carcinoma, by Dr. T. T. S. Harrison, of Selkirk; Some Applications of Entomology in Legal Medicine, by Dr. Wyatt Johnson and Dr. George Villeneuve, of Montreal; Physiological Demonstrations of Interest to Medical Men, by Dr. Wesley Mills, of Montreal; The Theory of the Eliminative Treatment of Typhoid Fever, by Dr. W. B. Thistle, of Montreal; Oral Surgery, by Dr. George Lenox Curtis, of New York; Vaginal Fixation of the Round Ligaments for Backward Displacements of the Uterus, by Dr. Hiram N. Vineberg, of New York; Clergyman's Sore Throat (?), by Dr. J. Price-Brown, of Toronto; Non-malignant Tumors of the Tonsils, with a Report of a Case, by Dr. H. D. Hamilton, of Montreal; Sinus Thrombosis associated with Acute Suppurative Otitis Media occurring during Scarlet Fever, by Dr. J. W. Sterling, of Montreal; Some Cases of Foreign Bodies in the Eye, in which the Electro-magnet was used successfully.—An Exhibition of an Artificial Nose Bridge, by Dr. F. Buller, of Montreal; Remarks on Cold Air in the Treatment of Pulmonary Tuberculosis, by Dr. Edward Playter, of Ottawa; Hereditary Cerebellar Ataxia, by Dr. D. Campbell Myers, of Toronto; A Report of Three Cases of Abdominal Section for Conditions Com-

paratively Rare, by Dr. H. Meek, of London, Ontario; The Early Atrophy of Muscles in Cerebral Disease, by Dr. Frederick G. Finley, of Montreal; Electric Baths and Dyspepsia, by Dr. A. L. De Martigny, of Montreal; and Militia Medical Reorganization, by Dr. W. Tobin, of Halifax. Other papers will be read by Dr. William Osler, of Baltimore, Dr. F. J. Shepherd, of Montreal, and Dr. J. C. Webster, of Edinburgh, Ontario.

**The Technics of Dilatation of the Perinæum in Labor.**—In the August number of the *Edinburgh Medical Journal* there is an abstract of an article by Dr. G. Coromilas, of Calamata, Greece, which is communicated by Dr. J. W. Ballantyne, who calls attention to the following method of dilatation of the perinæum, in order that it may be tried in protracted labors arising from rigidity of the perinæum: The woman should be placed in bed on her back or left side, with the legs as in natural labor. The mons, labia majora and minora, perinæum, and vagina should be thoroughly washed and rendered aseptic. The accoucheur should wash his hands very thoroughly, and grease them with the following ointment:

Vaseline.....	750 grains;
Cocaine,	each
Antipyrine,	45

The perinæum, vagina, and os uteri must also be anointed with the same ointment. The accoucheur then passes four fingers of one hand within the vaginal orifice, and makes some semilunar movements, first at one side and then at the other, so as to dilate the perinæum. After having made three or four such powerful movements, he introduces the fingers of the other hand, and repeats the performance. When the requisite degree of dilatation is achieved, he then passes the fingers fully into the vagina until the index, middle, and ring fingers touch the os uteri, and makes again the same movements at the same time as he pushes the perinæum outward with the palmar surface of the hand. When he feels the presenting part pressing upon the dorsal surface of his fingers he must then withdraw his hand and take on his other duties.

Dr. Ballantyne thinks that by this manœuvre we can guard the perinæum and the labia majora and minora from the rupture which happens so frequently, and that we can hasten the emptying of the uterus. Owing to the physiological action of cocaine and antipyrine, the dilatation of the perinæum and the delivery occur without severe pains.

**The Employment of Asbestos for Dressings.**—The *Union médicale* for July 18th contains an abstract of a review of a report made by M. Volintzoff to the Surgical Society of Moscow, which was published in the *Gazette des hôpitaux*. The results of the author's investigations are summed up as follows: The density of this product is much greater than that of cotton or of tarlatan; it is less porous than either of them and less hygroscopic. The escape of vapors takes place more slowly under a dressing of asbestos than under all others. It is not as good a conductor of heat as cotton is, but on this point, says the writer, the results of the investigation are not yet perfectly satisfactory. Asbestos absorbs the albuminoid solutions better than absorbent cotton or tarlatan does. In regard to the clinical observations, says the writer, M. Volintzoff thinks they are yet too small in number to enable him to give a definitive judgment. The product is not expensive, because it may be used several times.

## Lectures and Addresses.

### LECTURES ON ANGINA PECTORIS AND ALLIED STATES.\*

By WILLIAM OSLER, M.D.,

PROFESSOR OF MEDICINE, JOHNS HOPKINS UNIVERSITY, BALTIMORE.

#### LECTURE III.—ANGINA PECTORIS VERA.

##### PHENOMENA OF THE ATTACK.

**EXCITING CAUSES.**—There are three important elements—muscular exertion, mental emotion, and digestive disturbances. Any muscular effort which calls for increased action of the heart is liable to bring on a paroxysm. Heberden refers particularly to this: "They who are afflicted with it are seized while they are walking, more especially if it be up hill." Some patients who can not walk except on the level without bringing on a paroxysm can, however, take active horseback exercise. In extreme cases even an attempt to move in bed or assuming the sitting posture will cause an attack, or such slight exertion as stooping to lace the shoes. Hurrying to catch a train has been often the exciting cause of a fatal attack in the subjects of angina. The muscular and mental excitement of coitus is particularly dangerous, and has in many instances caused death. Two of my patients laid great stress on the terrible character of the attacks which had followed the act.

The well-known effect of mental emotion has never been better expressed than by John Hunter, who used to say that "his life was in the hands of any rascal who chose to annoy and tease him." And yet some of the victims of angina have not found mental excitement to be the most serious exciting cause. Thus, in Mr. Sumner's case, "a sudden turn in his easy-chair, while quietly reading at night, would start up the most tearing agony, while at other times an exciting speech in the Senate, accompanied with the most forcible and muscular gesticulations, would not create even the suggestion of a pain."—(Taber Johnson.)

For some of the worst attacks, however, neither muscular action nor mental emotion is responsible, since they come on when the patient is quiet and at rest, or may wake him from sleep. Cold is another exciting cause, particularly in the vasomotor form, but in the organic variety a cold wind, even the opening of a window in winter, or the cold sheets at night have been known to bring on an attack.

In almost every case in which the paroxysms recur with frequency the patient lays stress upon the condition of the stomach. Exertion immediately after a full meal, the eating of certain articles of food, and especially late suppers, are very apt to cause attacks; and, as I will mention later, there are instances in which the dyspep-

sia is so marked a feature that the character of the disease is entirely overlooked. In some patients flatulency is one of the most common exciting causes.

**SYMPTOMS.**—In the reports of the two cases which I read to you at the end of the last lecture I described the phenomena associated with the severe attacks. The physician has not often an opportunity of watching the onset and course of a paroxysm. Only once that I remember did a patient have an attack in my consulting room, Mr. S., to whose case I have already referred (XXVI). As he sat quietly in the chair, just after the completion of my examination, his eyes became fixed and he suddenly grasped both hands over the heart. For a moment the face did not change; then it flushed, and the neck became swollen, and the cervical veins full. The face became very much congested, and tears filled the eyes. The respirations, which had been 18, increased to 30 in the minute. The pulse, which had been 80, increased to 90, and became smaller and harder. Considering the increase in the respirations, and the congested state of the face and neck, I was surprised that the pulse changed so little. He remained immobile during the entire attack, which lasted just a minute and a half, passing off abruptly, and he at once began to put on his clothes.

There are two chief elements in the paroxysm: first, the pain—*dolor pectoris*; and second, the indescribable feeling of anguish and sense of imminent dissolution—*angor animi*.

The resources of the language have been taxed to describe the pain of angina pectoris. Patients speak of a hand of iron grasping the heart, or a band of metal encircling it and being gradually tightened; or as though an enormous weight was compressing the breastbone against the spine, or as though the whole chest were compressed in an iron case. In other instances the pain is associated less with pressure than with the sensation of stabbing, as though a dagger had transfixed the heart. While the maximum intensity of the pain is substernal (whence the name of *sternalgia* is derived), it may be in the upper or lower part of the breastbone, or over the body and apex of the heart. There are cases in which the chief agony is opposite the point of the xiphoid cartilage in the scrobiculus cordis. During an attack there may be marked tenderness over the region of the heart, or the left breast or the nipple may be tender to the touch. The pain may cease as abruptly as it began. One of Parry's patients said the transitions from acute pain to a state of ease were so sudden that at times he felt both extremes at the same moment.

A feature noted by Heberden and all the early writers was the radiation of the pain to other parts. Heberden says: "It likewise very frequently extends from the breast to the middle of the left arm. . . . The pain sometimes reaches to the right arm as well as to the left, and even down to the hands, but this is uncommon. In

\* Delivered to the Post-graduate Class, Johns Hopkins Hospital.

a very few instances the arm has at the same time been numbed and swelled." In an instance reported by Heberden the patient had attacks of pain in the left arm without any affection of the chest for fifteen years prior to his sudden death. The pain most commonly extends to the shoulder, to the left upper arm, and to the neck of the same side. When it extends to the arm and hand it is along the inner surface of the upper arm, and in the lower arm on the ulnar side in the distribution of the ulnar nerve. The feeling is one of numbness and tingling, or of pins and needles. There may be hyperæsthesia of the skin. Very often the chief pain is in the region of the elbow, or there may be, as in a case I have already narrated to you, a bandlike sensation around the wrist. Sometimes the radiation of the pain is more marked in the right arm and in the right side of the chest. Quain states that Dr. Morison has reported a case in which disease of the right side of the heart was accompanied by symptoms of angina affecting the corresponding side of the chest and arm. Curiously enough, as noted by Heberden, the pain in the arm may precede the angina attacks for years. Blackall, in the interesting appendix upon Angina to his work on *Dropsies*, refers to the account which Lord Clarendon gives of his father's sudden death, evidently from angina, "without one minute's warning or feare," though the pain is said to have been only in the arm. As this case is often referred to, I will give you the extract from the *Life*. Mr. Hyde was in church, and "found himself a little pressed as he used to be." Going to his home, "the pain in the arm seizing upon him, he fell down dead, without the least motion of any limb." In some cases there is sensory disturbance throughout the entire left side, a feeling of numbness or tingling in the neck, arm, and leg. There are instances on record of extension of the pain to the left testis, with swelling.

There are very interesting areas of cutaneous hyperæsthesia in the attacks, chiefly in the præcordia, about the pectoral fold, and sometimes along the side of the neck. They have been studied particularly by Mackenzie, and are rarely absent.

I do not know of any clearer view in explanation of the radiation of the pain in angina than that which was offered by the late Dr. James Ross, of Manchester. I will quote a brief summary. I do not know whether it was ever elaborated. "When a viscus was diseased there was local pain which might be regarded as of splanchnic origin (præcordial pain in the case of the heart). In addition, the irritation was conducted to the portion of the spinal cord from which the viscus derived its splanchnic nerve, and thence spread in the gray matter of the posterior horns, whence by the law of eccentric projection it was referred to the termination of the somatic nerves derived from the segment of the cord—the second and first dorsal in the case of the heart. This explained the pain shooting between the shoulders and down the inner side of the arm (second dorsal) to the

elbow and the ulnar border of the forearm and hand and ulnar fingers (first dorsal)." \*

The subsequent studies of Mackenzie and of Head have fully corroborated this view. Head † concludes that:

"1. In diseases of the heart, and more especially in aortic disease, the pain is referred along the first, second, third, and fourth dorsal areas.

"2. In angina pectoris the pain may be referred in addition along the fifth, sixth, seventh, and even the eighth and ninth dorsal areas, and is always accompanied by pain in certain cervical areas."

A very remarkable feature is the motor disability which may follow a severe attack. The left arm may not only be numb, but for a time almost powerless. Blackall says that he has seen instances in which the muscles of the arm and chest were not only painful, but were affected with a twitching noticeable by the patient, and visible to the observer. B. W. Richardson ‡ says "the voluntary muscles seem to be affected and rigid." Still more extraordinary is the fact, noted by Eichhorst, § of atrophy of the muscles of the hand supplied by the ulnar nerve.

Von Dusch, in his admirable *Lehrbuch der Herzerkrankheiten* (which remains one of the best works of its kind in the literature), refers the hiccough, the occasional difficulty in swallowing, the globus and uneasy feelings in the throat, and the gastric symptoms to sympathetic involvement of the phrenic and vagus nerves.

*Vasomotor disturbances* are almost constant in the attack. A sudden pallor of the face may be the first indication, and, as a rule, vasoconstrictor influences prevail in the severe paroxysms. A cold sweat breaks out upon the forehead and upon the arms and legs. In recurring attacks I have seen the skin of the hands like that of a washerwoman from constant soaking in perspiration. As in Case XXXV, there may be great pallor and coldness without sweating. Though rarely absent in the organic form of the disease, these vaso-constrictor disturbances are often more pronounced in the hysterical angina. The countenance is expressive of the deepest anguish, and may assume a deathlike, ashen hue. In other instances, as in Case XXVI, the face is suffused, or even deeply congested at the outset, and the veins of the neck may stand out prominently. More commonly in a fatal paroxysm there is pallor at first, which is followed by great lividity, as noted by Powell ¶ in a man who died in his consulting room.

Complaints of coldness and of swelling of the extremities are more frequent in the hysterical form.

In many cases of true angina the pain alone is experienced, but in severe paroxysms the other factor—the

¶ *Practitioner*, vol. xlvii, p. 234.

mental element, the *angor animi*—is also present. Latham was the first to distinguish clearly these two features of the attack: "The subjects of angina pectoris report that it is a suffering as sharp as any that can be conceived in the nature of pain, and that it includes, moreover, something which is beyond the nature of pain—a sense of dying." And he adds, "the dying sensation I have more frequently found to surpass the pain than the pain the dying sensation." The one is in reality a physical, the other a mental phenomenon, and was described by Heberden's unknown correspondent as the sensation of a universal pause in the operations of nature, or a sense of imminent and immediate dissolution. This feature of the attack was certainly referred to by Seneca (quoted by Gairdner) when he says, "As compared with any other disease, it is like the difference between being sick merely and giving up the ghost." Associated with this sensation there may be a feeling of air-hunger, or, as one patient expressed it to me, the same sensation that one has after holding the breath for as long as possible; yet the attack is not necessarily associated with any special respiratory disturbance.

The attitude during an attack is best described by the word immobile. If seized on the street, the patient grasps a lamp-post or leans against a wall, unable to stir until the agony has passed off. The attack usually comes on during some slight exertion, while the patient is in an erect posture. He may be quite unable to sit down. In other cases, when the attack comes on at night, the patient usually assumes the sitting posture, or other cases find slight relief by pressing a firm pillow to the chest, or by pressing firmly against the back of a chair. Immobility, however, is not a constant feature of a paroxysm of true angina. In Charles Sumner's case, Dr. Taber Johnson notes that he would at times get ease by walking the floor, quite unconscious of any increase in the agony by the exertion. In others the erect posture is assumed with the head and shoulders thrown back. One patient assured me that in moderate attacks on the street, by a strong effort of the will, he could continue to walk and the pain gradually subsided. This is like the gigantic farmer, of whom Forbes tells, who thought he could rule the disease as he did his horses.

STATE OF THE HEART AND PULSE.—Heberden states that "the pulse is at least sometimes not disturbed by this pain, consequently the heart is not affected by it." Parry is more positive as to the occurrence of change, holding that "whatever may be the state of the pulse as to regularity, I believe we shall always find it become more or less feeble according to the violence of the paroxysm." The question is one about which very diverse opinions are held, and you will find in vol. i of the *Lancet*, 1891, several interesting letters which passed between Professor Gairdner and Dr. Harrington Sainsbury. It is quite evident that there are good authorities who accept the statement that in some cases at least the paroxysm is not associated with special change in

the pulse, and consequently not in the action of the heart.

The opportunities for observing the paroxysm do not come very often, and when they do the condition of the patient is such that our efforts are directed rather toward his relief than to the study of special points in the case. In an attack of moderate severity, such as Mr. S. (Case XXVII) had in my consulting room, the pulse, which had been 80, increased to 90 in the minute, and became smaller and harder. The tension certainly became increased, but I had not time to do more than count the radial beats for half a minute and to listen hurriedly to the heart sounds before the attack was over. In Case XXXII, in the first paroxysm in which I saw him, January 3d, the state of the pulse threw me a little off my guard; it was full and regular, and did not change much, if at all. I am not certain that it was an intense attack, as he threw himself about on the bed, the face was flushed, and there was a good deal of commotion. Subsequently the pulse became feeble and irregular, 115 a minute. Then, on the day before his sudden death, the pulse was soft, regular, without special tension, and 90 a minute. In Case XXIII the pulse fell in the paroxysm to 42 in the minute and became small and soft. For days the range had been about 96. For several hours after the paroxysm the beats at wrist and at heart ranged from 40 to 50 a minute. Subsequently the heart beats became more numerous than the pulsations at the wrist, ranging from 60 to 70 a minute. In Case XXXVI I did not see the patient in his first paroxysm, but three hours later the pulse was 90, of fair volume, regular, and without increase of tension. On succeeding days, as the attacks increased in frequency, the pulse became small, feeble, and at times could not be felt. Following a series of severe attacks, the pulse may be persistently small and irregular, as in Case XXXV. In Case IV, that of a man, aged forty-five, admitted to the University Hospital, Philadelphia, February 24, 1887, I had several opportunities of feeling the pulse during the paroxysm. On the 25th the pulse was 80, regular, and small, and the respirations 34. During an intense paroxysm the pulse became more and more feeble and at last *could not be counted*. This sentence I find underlined in my notes.

Osgood has called attention \* to a remarkable difference in the radial pulse of the two sides. The case was one of hysterical angina in a young girl. Huchard (p. 524) refers to its occurrence in true angina, both in the attacks and in the intervals. The heart's action in severe spells is probably always disturbed, the force of the impulse weakened, and the rhythm altered. There are two changes which have been most common in my experience—namely, the shortening of the long pause and the occurrence of gallop rhythm. Whatever may be the mechanism of the production of these changes, they

\* *American Journal of the Medical Sciences*, October, 1875.

both, I think, mean the same thing, weakening of the ventricular systole from dilatation and debility of the muscular wall. The case which called my attention to the fetal heart rhythm following angina I saw with Dr. Underwood, at Pittston, Pa., in February, 1889. The patient, Case VI, aged sixty, had well-marked signs of myocarditis, with cardiac asthma and severe pains about the heart and down the arm, so that he had to take morphine freely. I saw him shortly after an attack: the pulse was 104, weak, and irregular. At apex and base the sounds were clear, rather ringing in quality, and all distinction between the two seemed lost. "There was a shortening of the pause between the second and the first sounds, so that they followed each other in a uniform series, as in the fetal heart beat." This, so-called, embryocardia was a most persistent feature in Case V, and was present also in Cases XIX, XXIX, XXXV, and XXXVI. The gallop rhythm is, I think, met with quite as often, and was present after attacks in Cases XI, XIII, XIX, XXXII.

It does not fall to the lot of many physicians to witness a sudden death in angina, but there are observations to show that the pulse beats (and the heart) stop abruptly. Potain mentioned a case to Huchard (p. 525), and in the case of our good friend, Mr. E., Case XXXV, Dr. Thayer, who was present, tells me that the death seemed instantaneous—the pulse ceased *at once*, and there were no further heart beats. As I before remarked, the mode of death resembles that produced by Kronecker's heart puncture.

As the subjects of angina pectoris present very frequently the signs of arterio-sclerosis and increased tension, you will often find a ringing, accentuated, aortic second sound. An aortic diastolic murmur is much more common than my figures would indicate. As I have already mentioned, mitral-valve disease is rarely present. There is a very interesting feature in certain cases of angina with recurring attacks—viz., that with the development of a mitral systolic murmur the attacks have ceased as though a relief of the intraventricular pressure had been effected by the establishment of a relative mitral insufficiency. My attention was called to this point by Musser, who has had several illustrative cases, and Broadbent has dwelt particularly upon this point.\*

**PERICARDITIS.**—During a severe attack pericarditis may develop from the involvement of the epicardium in a softening infarct (Kernig †). Dock has described the onset of pericarditis in a case of thrombosis of the coronary artery, due to the same cause. Hood ‡ records a case in which the friction developed twenty-four hours after the attack, and subsequently there were signs of effusion. In the discussion which followed, De H. Hall mentioned a similar case.

(To be concluded.)

## Original Communications.

### A CASE OF THROMBOSIS OF THE LATERAL SINUS, WITH RECOVERY AFTER OPERATION.\*

By JOHN L. ADAMS, M. D.,

ATTENDING SURGEON TO THE NEW YORK EYE AND EAR INFIRMARY;  
ST. BARTHOLOMEW'S NIGHT CLINIC FOR DISEASES OF THE EYE, EAR, AND THROAT

THREE years ago I had the honor to report a case of thrombosis of the lateral sinus in which operative interference failed to save the patient's life. I made that case the text upon which to base a plea for early exploration of the lateral sinus when its involvement was suspected, and also that this and other operations for troubles secondary to ear disease should be performed by the aural rather than by the general surgeon. To-day I feel gratified to be able to report a successful case of this nature in which I operated in my capacity as aural surgeon:

I was consulted on the 9th of last March by a lady twenty-four years of age, who, until five years ago, had always enjoyed very good health. At that time she caught a severe cold and her left ear became affected. She consulted a doctor, who prescribed the instillation of drops. In a few days otorrhœa began, which persisted for a year, and finally ceased under treatment by syringing with lukewarm water and chamomile tea. From that time on she had tinnitus in this ear and a feeling of dizziness whenever the least pressure was made on the external auditory canal. With these exceptions she had suffered from no disease of any kind until six weeks previous to her consultation with me. At this time she caught another severe cold, and during a paroxysm of coughing was seized with a sharp pain in the same ear. Four days later she consulted a well-known aural surgeon, who advised syringing the ear with a warm solution of boric acid three times a day. This seemed to give her relief and the inflammation apparently subsided.

Ten days before I saw her she went to the doctor complaining of severe pain in the same ear. He advised an operation, probably paracentesis of the drum membrane, but this was declined, and the patient was then told to put hot onions in her ear. This was done, and after two days a discharge appeared, but the pain persisted. She then consulted the doctor again, and was told to syringe the ear with a warm solution of boric acid. This failed to control the pain, so three days later a leech was applied, and afterward hot fomentations were used. Still the pain grew worse. Two days after the leech was applied a swelling appeared behind the ear. All the symptoms were worse on the following day. During the next night she fainted a number of times, and on the following day had chills at short intervals, vomited twice, and was too prostrated to be able to sit up, and the temperature rose to 104° F. The pain was at this time principally confined to the ear and the frontal portion of the head, and, as she described it, "felt as though some one was twisting a knife around in her head." There was no profuse perspiration and no involvement of the throat or of the

\* Read before the American Otological Society at its twenty-ninth annual meeting.

eyes. The next day she consulted me, and that same afternoon submitted to an operation at the New York Eye and Ear Infirmary.

On admission to the hospital the patient complained of intense pain over the left mastoid, which was swollen and very sensitive to pressure, especially at the tip. This swelling extended down the neck, but no cordlike condition of the jugular vein could be distinctly made out. Whitish purulent masses were found in the external canal and the posterior wall was swollen and boggy; the membrana tympani was nearly destroyed, only the upper segment remaining. The head of the malleus was carious. The mucous membrane of the tympanum was edematous and bathed in a suppurative discharge. The patient was greatly prostrated, pulse rapid and weak, temperature 103.4° F. She still had chilly sensations and vomiting. On examination of the eyes I found a slight retinal hyperæmia but no evidences of beginning choked disc.

The patient was admitted to the hospital at 4.30 P. M., and at six o'clock the operation was commenced under ether. The hair was shaved from about the vicinity of the mastoid, and the integument of that region and the neighboring parts thoroughly cleansed and rendered aseptic with soap and water and a solution of bichloride of mercury (1 to 1,000). I then made a vertical linear incision about a quarter of an inch behind the posterior border of the external osseous meatus, extending from the tip of the mastoid to half an inch above the posterior root of the zygoma. From the upper extremity of this I made another incision directly backward for about three quarters of an inch. These incisions penetrated the periosteum, which was immediately elevated with the soft tissues by means of a periosteal elevator. The outer bony table of the mastoid was then removed with a chisel, and I found that the posterior osseous wall of the external canal, together with the intercellular partitions in the mastoid, had been destroyed, and that the cavity was filled with pus and cholesteatomatous material. This cavity and that of the middle ear I carefully curetted and thoroughly cleansed with a solution of bichloride of mercury (1 to 5,000), being very particular to remove all sources of infection. I then uncovered the sinus by extending the opening in the bone backward and removing the inner table by means of a chisel and rongeur forceps. As this plate was removed a small amount of pus escaped from the sigmoid groove about the sinus. I then exposed the sinus for fully an inch in order to facilitate the operation and to cleanse it externally. After curetting away a few adhesions and washing it thoroughly with a solution of bichloride of mercury (1 to 5,000), the sinus seemed to pulsate, to be of normal consistence, and the walls did not appear to be thickened. I decided, however, to follow my usual custom and make an exploration so as to be perfectly sure in regard to the existing condition. I therefore introduced a sterilized hypodermic needle into the sinus and found that it contained no blood. I then laid it open with a scalpel for about three quarters of an inch and found it to contain a cordlike mass which proved to be a dry clot. I then passed a small curette upward and backward toward the torcular Herophili and removed this clot until fluid blood appeared. The contents below were removed for as great a distance as the curette could be introduced, but no fluid blood could be obtained from this side. The sinus was then irrigated with a normal salt solution and packed with iodoform gauze. The upper part of the wound was sutured and

the usual antiseptic dressing applied. The recovery from ether was good.

March 10th.—The patient slept fairly well and was quite comfortable during the night. The temperature this morning was 104° F. Patient was quite weak and coughed considerably. Complained of stiffness in the neck. Examination of the chest revealed nothing. She was given half an ounce of whisky every two hours, a twentieth of a grain of sulphate of strychnine, and half a grain of codeine every three hours. In the afternoon the dressing was changed. The wound was found to be clean, with no discharge. The temperature remained high and the pulse weak.

11th.—The patient coughed a good deal during the early part of the night, causing pain in the head, but slept most of the time. This morning the temperature had fallen to 101°, pulse was better, and the patient seemed brighter and stronger. The wound was dressed.

12th.—Patient complained of pain in her left ankle and left wrist. The pain in head and neck appeared to be subsiding. The pulse was stronger and the patient seemed better this morning. A lead-and-opium wash was applied to the ankle and wrist. In the afternoon the wound was dressed, the stitches removed from its upper portion, and a pocket of pus was found beneath the scalp. After the dressing the temperature rose to 102.4° F. As the bowels had not moved since the operation an enema was given, but was not retained.

13th.—Patient slept well after taking five grains of phenacetine and ten grains of trional. Coughed less, had less pain, and could move in bed with less discomfort. Temperature, 102.6°; respiration easy and regular; pulse, 100, and of better tension. A small amount of pus found beneath the scalp, otherwise the wound looked well.

14th.—Patient coughed very little, and moved about in bed better without assistance. During the night she was restless, and her temperature rose to 103°, but after the administration of ten grains of phenacetine fell to 99°.

15th.—Patient was bright this morning, but the temperature rose to 102.3°.

19th.—The temperature was quite irregular for the preceding three days, ranging from 99° in the morning to 103° in the afternoon. There were no chills, no profuse perspiration, and no delirium at any time. The wound was dressed daily. It was now closing from below with healthy granulations. The pocket under the scalp was now free from pus. The sinus was still uncovered and collapsed.

22d.—Temperature for past three days normal, except for slight rises to 99.3° during the afternoon. The patient was now comfortable, sitting up in bed, and in every way stronger and better. The cough had ceased, but occasionally she complained of pains in her limbs.

25th.—Sinus still uncovered, and the wound closing slowly.

April 1st.—Temperature normal for a week. Patient slept well, had a good appetite, and was allowed out of bed, but was still unable to walk around. The wound was closing rapidly.

8th.—The patient was able to walk about the ward without difficulty. She had no pain, and the wound was becoming well filled with granulations.

11th.—Patient was discharged from the hospital with the wound nearly healed.

May 1st.—Patient was seen at my office, and the wound was then entirely healed.

Thrombosis of the cerebral sinuses was, I think, first accurately described by Abercrombie in 1818, but it was reserved for Zaufal, in 1880, to suggest the practicability of opening the lateral sinus and removing the inflammatory products. The same surgeon, four years afterward, reported a case in which he washed out the sinus with a two-per-cent. solution of carbolic acid, but the patient died two weeks later of pneumonia. This inaugurated a pronounced advance in the surgical treatment of this disease. In the majority of cases noninterference results in the death of the patient, although recovery may take place, as is shown by isolated cases that have been reported in which symptoms held to indicate thrombosis have abated, and by autopsies that have occasionally revealed old obliterations of the lateral sinus and jugular vein. Some aural surgeons have taught that operative interference in these cases should be confined to the ear and mastoid alone, at least until the further progress of the case shows this to be insufficient. This was the view held by so able an aural surgeon as the late Professor Moos, who six years ago reported a case successfully treated by the evacuation of the pus in the mastoid cells. It is true that, as he says, "if we remove this pus the chances of a natural recovery are much improved," but how good these chances are may be inferred from the following passage in the same paper: "Thrombosis of the lateral sinus may be recovered from if the patient survives the consequences of the breaking down of the thrombus. Either the lumen of the vein finally becomes free through the total breaking down of the thrombus and the restoration of the normal circulation, or the thrombus becomes united with the vein into a solid cord, and a sufficiently extensive anastomotic circulation becomes established." Pickering and others have reported similar cases in which patients with marked symptoms of thrombosis have recovered after simply a thorough opening, cleansing, and drainage of the mastoid and middle ear without interference with the sinus. But I can not approve of this method. Quite a number of both successful and unsuccessful attempts to ameliorate the condition by operations upon the sinus and the jugular vein have been made, and, so far as I have been able to learn, in the unsuccessful cases the patients appear to have died in spite of rather than on account of the operation. The condition present is one of great danger, and when a delay is made to note the progress of the case after evacuating the pus from the mastoid cells, an opportunity is given for the thrombus to break down and for its portions to be carried into the circulation to cause infarctions and pyæmia, which may be, but seldom will be, survived by the patient. The few who recover demonstrate only the wonderful recuperative powers which the body will occasionally exhibit; they do not prove that it is good surgery to avoid interference with a pathological condition which of itself irrespective to a certain degree of its cause, imminently threatens death.

The first successful cases of which I have found a

record are those reported by Mr. Arbuthnot Lane in 1889, in which he ligated the jugular vein, opened the sinus, and removed the clot. Mr. Ballance followed in 1890 with four cases treated in a similar manner, two of which were successful. During the same year Sulzer opened the sinus and removed a foetid mass in two cases; one patient died, one recovered. In 1893, Mr. Lane reported ten cases of subdural abscess, periphlebitis, and thrombosis secondary to aural disease. No operation was performed on the sinus or vein in three cases. Seven patients had the jugular vein ligated, and six had, in addition, the sinus opened and its contents removed. Of these seven, only one died, and the autopsy revealed in that case an extension of the thrombus to the other cerebral sinuses. It would require too much time and space as well as impose too great a tax upon your patience for me to enumerate the gentlemen who have followed the lead of these pioneers in this branch of aural surgery, and if I name Macewen, of Glasgow, Pritchard, of London, Crockett, of Boston, Moss, of Texas, and Cleghorn, of New Zealand, it is only to indicate how extensively this operation has been accepted and is successfully practised to-day.

I can not unqualifiedly concur with Griesinger that the diagnosis of thrombosis of the lateral sinus is, at best, only a diagnosis of probability, although it is frequently obscure, and Jansen maintains that in pure sinus thrombosis without degeneration all symptoms may be completely wanting. Fortunately, the complications of aural disease from which it needs to be distinguished are intradural or extradural abscesses, which demand the same exploratory procedure as the trouble we are now considering, and are not infrequently associated with it. The diagnostic symptoms may be given as severe pain in the ear, persistent headache, chills, high and fluctuating temperature, rapid pulse, stupor, vomiting, and constipation, all usually associated with a cessation of the otorrhœa. I believe that Wreden was the first to call attention to the diagnostic importance of the high fluctuations of the temperature in this condition, which is very great, although not present in all cases. According to the statistics compiled by Forselles, the daily variations of temperature are greatest in the uncomplicated cases. Chills are usually among the early symptoms, but may appear in the second or third week, or later, or may be entirely absent. Vomiting is an initial symptom in about twenty-five per cent. of uncomplicated cases, somewhat more frequent when other cerebral lesions are present. Vertigo is an initial symptom in about thirteen per cent. of uncomplicated cases, in from thirty to thirty-five per cent. when meningitis is present, and rarely occurs later in the disease. Headache is usually diffuse, and is frontal in only a small percentage of cases.

Edema of the temporal region is stated by Moos to be a pathognomonic symptom of thrombosis of the lateral sinus; Bennett believes this is true of edema and tenderness over the post-mastoid region, particularly

over the mastoid foramen, while Griesinger maintains the importance of œdema over the mastoid. These are all, I think, unreliable. Distention of the superficial veins is dependent to a large degree on the extent of the thrombus, and is seldom very marked, but it is good corroborative evidence when present. The most valuable diagnostic sign which can be obtained is phlebitis of the deep veins which communicate with the sinus, particularly of the internal jugular. This vein may then be appreciated as a hard, tender cord in front of the edge of the sterno-cleido-mastoid in its upper part, so tender that pressure will sometimes elicit expressions of pain when the stupor is so marked as to make it difficult to rouse the patient. At times, pain obtained by pressure on the upper part of the posterior cervical triangle will indicate phlebitis of the deep cervical veins which are too small and too deeply situated to be individually felt. Choked disc may be present in thrombosis of the lateral sinus, but it is not properly symptomatic of this condition. It shows an interference with the circulation through the retinal vessels, which may be produced by an extension of the thrombus into the cavernous sinus or by the presence of a meningitis which extends beyond the immediate vicinity of the sinus and forms a complication. I do not think it is ever present in a pure, uncomplicated case of this nature.

The relation which the extent of the thrombus and the general septic infection bear to each other is uncertain. Lane believes that the latter is the more severe the less the thrombus is extending, while I understand Forsselles to maintain the contrary opinion, and Koerner holds that if the occlusion by the thrombus is complete there will be little or no infection of the general system. I do not propose to attempt any explanation of such disagreement, but mention it simply to show what a weak basis any surgeon has upon which to rest a decision to leave either a large or a small thrombus *in situ*, unless some complication is present which serves to render the operation nugatory.

In regard to the operation: The first procedure in every case should be to thoroughly evacuate all of the products of inflammation from the middle ear, antrum, and mastoid cells. After this has been done, the wound in the bone should be enlarged backward, and the inner table removed so as to expose the sinus, which then lies in the wound convenient for examination. A thoroughly sterilized hypodermic needle should then be introduced and an attempt made to withdraw fluid blood. If properly done, I believe this procedure to be without danger to the patient, and the evidence thus obtained is convincing in regard to the presence or absence of a thrombus. I have done this in quite a number of cases where thrombosis was suspected, and have never had occasion to regret it. If fluid blood is not obtained in this manner a thrombus is present, and three operative methods are open to the surgeon: first, to simply ligate the jugular vein, as suggested by Mr. Lane in 1891; second,

to open the sinus and remove the thrombus with a curette; third, to combine these two operations. Simple ligation of the jugular vein has not been done many times and does not seem to have been attended with as great success as the two others have been. The advice of most of the English writers is to ligate the vein first and afterward open the sinus, but I should reverse this—open the sinus first, observe the conditions there present, and then, if advisable, ligate the vein. In the case I report to-day I did not consider this ligation necessary, and the result has proved that it was not, but in many cases, particularly where the thrombus is septic and breaking down, it may be judicious not only to ligate the jugular vein, but to cut it across, bring the distal part out of the wound, and remove the septic clots by means of irrigation with some suitable solution, as was done by Mr. Ballance in one of his cases. At the close of the operation the lumen of the sinus must be occluded by packing and pressure and the wound dressed with the utmost antiseptic care and precaution.

Recovery is fairly prompt. When death occurs it is usually in consequence of the extension of the thrombus to the cavernous and other sinuses, or from pyæmia, but the operation is severe and the danger from shock must not be forgotten.

In conclusion, I wish once more to urge that exploration of the lateral sinus with a sterilized hypodermic needle is a safe and justifiable proceeding in doubtful cases, that the operation described affords a better chance for the patient's life than any other yet suggested, and that this operation belongs to the province of aural surgery and should be performed by the aural surgeon.

## THE TREATMENT OF ATROPHIC RHINITIS.

WITH A CASE.\*

By W. PEYRE PORCHER, M.D.,

CHARLESTON, S. C.

THE object of this paper is to elicit a consensus of opinion in regard to the best method of treatment of atrophic rhinitis. It is pitiable to find out what desperate measures are resorted to for the relief of this condition, because people believe that doctors are helpless to relieve them, and therefore willingly accept the most violent or disgusting remedies. For example, I was recently informed by a comparatively intelligent man that he had been almost cured by inhaling his own urine. This he practised continually until he was induced to discontinue it by the fear of gonorrhœal or syphilitic contagion in the nose and eyes.

It is hard to find any two authors who agree upon a specific line of treatment. The journals teem with innumerable suggestions, the majority of which are generally utterly useless, because they are not directed to

\* Read before the American Laryngological Association at its eighteenth annual congress.

the cause of the disease, and very often even aggravate a condition which is already almost if not quite incurable. In order, therefore, to get the best result possible—which is at best a palliative one—it is necessary to determine what is the exact cause of the disease and what is the *status præsens* of a case which aggravates the condition and completely obviates Nature's efforts at repair.

Many theories have been advanced of the aetiology of this disease. Dr. Mackenzie says: "That atrophic rhinitis always appears as a sequel of a pre-existing catarrhal inflammation is rendered highly probable from a number of clinical and pathological facts. If the clinical history be accurately taken, it will point to a pre-existing catarrhal process. As has been indicated above, the rapidity with which the hypertrophic passes into the atrophic form of rhinitis is proportionate in all probability to the possession of some constitutional taint, such as congenital or acquired syphilis."

Dr. Bosworth says that a purulent rhinitis in childhood is a catarrhal process in the first year and a catarrhal process always, and that it consists essentially in an increased secretion of mucus in the earlier stages, together with a rapid desquamation of epithelial cells, which, running its course as a purulent disease in from five to ten years, develops finally into what is known as atrophic rhinitis. The disease, in fact, is the first stage of so-called dry catarrh or ozæna. The theory that a purulent inflammation of the accessory cavities was the cause of atrophic rhinitis was advanced many years ago by Michel.

An hypertrophied mucous membrane was found in one nostril with atrophic degeneration in the other, but that does not prove that either condition is dependent upon the other.

Syphilis frequently results in atrophic degeneration of one or both nostrils as a natural result of the ravages of that disease.

Purulent discharges originating in any of the accessory sinuses or resulting from a simple acute inflammation may likewise result in atrophic degeneration, with more or less complete destruction of the muciparous glands and follicles.

The effect of pus on the epithelia and glandular structures, especially in the nose, need not be dilated on here, but it has been a well-observed fact that atrophic degeneration almost always begins upon the middle turbinate bones, and it has also been noted that scabs which become incrustated there and elsewhere almost always contain some particles of pus incarcerated on the under surface of them. Of course, it may be said here that atrophy may result from the simple non-use of any organ without the presence of any inflammation—simple or purulent—to produce it.

Paradoxical as it may appear, but nevertheless true, the nostrils of habitual mouth breathers or those to whom the nose is little more than an ornament on the

face, instead of becoming larger from atrophy of the mucosa, become narrower and more occluded, almost as though an hypertrophic instead of an atrophic process had been established, so that it can not be said that atrophic degeneration is in any case due to simple non-use of the organ—first, because of the reason above cited, and, second, because the worse cases of atrophic rhinitis are often found in those who live in workshops where they breathe the most foul air, sooty emanations, etc.

Atrophic rhinitis occurs quite often at a very early age. Large green scabs forming complete casts of the nose have been found in children of seven years and younger. In these cases the aetiology of hypertrophy—dust inhalation, etc.—has to be entirely excluded. This was notably the case in a child of six or seven years that was brought to the writer several years ago. There was no specific taint in this case, and hence there could be but one cause to which the disease could possibly be attributed—namely, a prolonged acute rhinitis, resulting in an acute cold, which had been left to run on until the nasal mucosa was almost entirely destroyed.

It is apparent, then, as has been stated by some writers, that atrophic rhinitis is not a disease *per se*, but is the result of any inflammation, acute or chronic, specific or non-specific, whether excited by exposure to cold or continuous inhalation of irritating dust, vapors, etc., which ends in a purulent discharge, and which may or may not involve the accessory sinuses, but is sufficiently prolonged to wash away the epithelia and destroy the nasal mucosa, turbinates, etc. If this is true, what measures should best be instituted for the relief of the patient, and what hope have we that the formation of scabs may be stopped?

It would be but a simple matter to search for and give free outlet to all pus cavities, scrape away carious bone, and wash out scabs, etc., but it has heretofore been the humiliating experience of the writer, in common with other physicians, to find that the scabs continued to reform exactly as they did before, and that the douche had to be used as persistently as ever.

It is with great hesitancy, therefore, that I venture to offer a method of treatment which in one case at least has exerted a marked influence in stimulating the nasal mucosa to an almost hypersecretion, and causing the scabs to move from their former site, so that they might more easily be blown out of the nose.

The patient was a lady, aged thirty-four years, without any specific taint that I could detect, of splendid physique, and in excellent health otherwise. The scab formations were first noticed about fifteen or more years ago, following an attack of measles. Since then she has suffered much at the hands of many doctors and from varied treatments. The inferior and middle turbinates are gone on the left side and seriously injured on the right. When she came to me I first suspected involvement of the accessory sinuses, but, on account of uncertainty, I resorted to almost every kind of local stimulating application in combination with iodide of potassium, freely administered internally. This was given not for

its antisyphilitic effect, but on account of its influence on lachrymation, etc.

Scarcely any local improvement resulted from this. Finding, then, that the left side was the most seriously affected, I opened the antral and ethmoidal sinuses on that side thoroughly, and irrigated them daily with antiseptics, but this also failed to afford relief.

Acting upon the suggestion of the Gottstein cotton tampon, I saturated a pledget with a strong solution of iodine, glycerin, and the iodide of potassium as follows:

R Iodide of potassium..... 3 ijss.;  
Iodine..... gr. xl;  
Glycerin..... ʒ j.

M.

This was packed daily between the upper turbinate and the roof of the nose, and allowed to remain for twenty-four hours. Profuse lachrymation and supersecretion were caused, and the scabs were forced from their old location and collected in the lower nostril and were blown out. The scabs still continue to form, but the patient is enabled to get them out much more readily and to partially do away with the use of the nasal douche.

As already above stated, this paper is written purely in hopes that it may elicit the best practical measures for the relief of these cases, because they are surely regarded at present by the laity and general profession as the *opprobria medicorum par excellence*.

## ANÆMIA CAUSED BY TAPEWORMS

(*BOTHRIOCEPHALUS LATUS*)

OBSERVED IN THE UNITED STATES.

By JARL HAGELSTAM, M. D.,

HANGO, FINLAND.

As far as my knowledge goes, there has not to this date been placed on record in the medical literature of the United States any case of that characteristic anæmia which is caused by the intestinal parasite *Bothriocephalus latus*, quite commonly found in some parts of Europe. Neither do I know if this parasite is frequent in America, but, as it is no doubt imported there by hundreds of immigrants every year, it would be astonishing if it did not there also create the disease which it seems to be able to cause occasionally.

In Europe the *bothriocephalus* is frequently found in the Baltic provinces and in St. Petersburg, in Poland, Finland, Sweden, in some parts of Switzerland, Germany, and Italy. Outside of Europe it is reported to be frequent in Japan.

This tapeworm has generally been considered as one of the most innocent among the intestinal parasites, until, in 1885, Hoffmann, of Dorpat, for the first time drew attention to the fact of its being able under certain circumstances to cause a severe, sometimes fatal anæmia, presenting the same clinical symptoms as the disease which, in 1868, Biermer first described under the name of pernicious anæmia.

This *bothriocephalus* anæmia was shortly after described also by Botkin in St. Petersburg, Reyher in

Dorpat, and Runeberg in Helsingfors. In an excellent monograph, Dr. O. Schauman treated the rich material found at Runeberg's clinical department of the University Hospital at Helsingfors (Finland), proving that the *bothriocephalus* anæmia with respect to the symptoms and the pathological alterations of the blood in no way differed from Biermer's "pernicious anæmia," although the former in most cases can be cured by the expulsion of the tapeworms.\* The reason why this generally innocent parasite in some cases creates such a severe disease is explained by Dr. Schauman, in accordance with Schapiro and others, by supposing some kind of intoxication or infection by some chemical matters produced by the parasite under certain circumstances (disease of the worm).

The symptoms of the *bothriocephalus* anæmia—viz., excessive wax-yellow paleness of the skin and of the mucous membranes and a slightly icteric coloration of the conjunctivæ in combination with headaches, epigastric pains, lack of appetite, and general weakness with or without rise of temperature, and contrasting with the mostly undiminished subcutaneous adipose tissue—are characteristic enough to be recognized at once by one who is familiar with the disease. Not less characteristic are the changes of the blood. By microscopical examination the red blood-corpuscles are found greatly diminished in number and show remarkable changes with respect to size and form (poikilocytosis), while the number of the white corpuscles seems to be increased. The fæces show, under the microscope, quite a number of the characteristic eggs of the parasite even in cases where the patient himself does not know that he carries a worm in his bowels.

Not very seldom it happens, a worm cure having been administered, that no worm is expelled, while by a repeated examination of the fæces eggs can not be found and the patient recovers. In those cases the parasite has been killed and putrefied without appearing in the excreta.

Relapses are not infrequent, and sometimes occur after years of perfect health. Whether in those cases a new infection has taken place or whether some living worm heads have remained in the bowels and produced new proglottides is not easy to prove. The patients often give a history of a similar disease at some previous time, from which they have recovered without any medical treatment. Probably the worm in those cases was expelled spontaneously or died and became absorbed. The relapse then, however, often proves severer and not seldom proves fatal if the worm is not expelled soon enough.

In a paper read at the *Versammlung deutscher Naturforscher und Aerzte*, in Berlin, 1886, Mr. Runeberg reported nine deaths from "pernicious anæmia" in the medical department of the hospital in Helsingfors dur-

\* Ossian Schauman. *Zur Kenntnis der sogenannten Bothriocephalus-anæmie*, Helsingfors, 1894.

ing the years 1877-'83, and in most of these cases the bothriocephalus had been found at the autopsies. Since that time the faeces in every case of anaemia have been examined, and whenever eggs of the worm have been found, anthelmintics have been administered. During the years 1883-'86 nineteen cases of "pernicious anaemia" were thus treated, and of those only one was fatal—the day after the patient entered the hospital.

Dr. Schauman's monograph includes seventy-two cases, of which twelve ended fatally. To those who wish to study the subject more profoundly this excellent work is to be highly recommended.

Judging from the communications which have appeared in medical literature to this date, it seems very strange that bothriocephalus anaemia has been reported only in the Baltic provinces, in St. Petersburg, and in Finland, with the exception of a few single cases in Bern (Switzerland) and in Berlin and Königsberg (Germany), while, until recent times, there never was published a record of this disease, for instance, in Sweden, where the bothriocephalus is one of the most frequently found intestinal parasites. The first communication of this kind was made at the meeting of the Swedish Medical Association on the 14th of April this year by Mr. Bruhn-Tuhraeus, who reported two cases of bothriocephalus anaemia (*Hygieia*, May, 1896).

Another recent communication of that same disease is made by Mr. Babes, of Bucharest, who states that the bothriocephalus anaemia is not uncommon in Roumania.

The peculiar fact that this severe and characteristic disease seems not yet to be universally recognized, and therefore, no doubt, is apt to escape due attention in countries where it probably exists, may serve as an excuse for my reporting two cases of bothriocephalus anaemia which I happened to treat in the United States, although my notes are far from complete, as I then had no idea of publishing them.

In the winter of 1889, during a few months' stay in New York, I was one day called to see a countrywoman of mine, a workman's wife from Finland, twenty-nine years old, living in Harlem, New York. The patient had always enjoyed good health until, for the last few weeks, she had begun to feel weak and tired and to suffer from headaches and lack of appetite, which symptoms steadily increased until, for about a week before my visit, she had been unable to leave her bed.

I found the woman very weak, utterly pale, with that characteristic faint yellowness of the skin, the mucous membranes, and the conjunctivæ which at first sight makes it possible to distinguish pernicious anaemia from chlorosis as well as from those secondary anæmic conditions which are essential, for instance, to an ulcer or a cancer of the stomach or to consumption. Pressure on the sternum and the epigastric region was painful. A loud murmur was heard over the jugular veins, and also a soft murmur at the apex of the heart. There were no symptoms from other organs of the chest or abdomen, and there was no fever. In answer to my questions the patient said that she sometimes had passed tapeworms—not later, anyhow, than two years before.

Although I had no opportunity of making any microscopic examination either of the faeces or of the blood, I did not hesitate to prescribe a worm cure, besides some iron and arsenic pills, and told the patient's husband to report to me further about her. I did not hear anything more of her, however, until about six weeks later, when the woman called herself to tell me that she was in perfect health, having been able for the last week to do all her household work, even to scrub the floor. She looked strong and healthy, the color had returned to her cheeks, and her appetite was good. Quite a number of tapeworms had been expelled.

Another similar case came under my observation in Calumet, Michigan, in the month of June, 1895. The patient was a boy, twelve years old, who seven years before had immigrated with his parents—working people from Finland—and his four sisters and brothers. Both the parents and all the children had at times passed tapeworms, but were not known to have had any other illness. Once, a year before, the patient had suffered from a disease with symptoms similar to those which he was presenting now, but under the care of a physician had recovered after a few weeks' illness. Now again he had for some time felt weak and suffered from severe headache and dizziness. His appetite was completely lost and he had nausea after eating. Getting steadily worse, and at last unable to be out of bed because of the increasing weakness, he was brought to town for help, driven in a carriage for about ten miles.

On his arrival the patient was quite prostrated, was hardly able to answer questions, and complained of dizziness.

*Status Præsens, June 5, 1895.*—The patient is physically well developed, the subcutaneous tissues in good condition. The skin and the mucous membranes are utterly pale, and, like the conjunctivæ, slightly yellow. Over the jugular veins there is a loud murmur (*Venen-geräusch*). There seems to be some dilatation of the heart and a distinct murmur is to be heard both at the apex and at the base. The pulse is weak and soft, beats 130 in the minute. Temperature, 102°. Pressure on the sternum and the epigastric region is painful. No albumin in the urine. Bowels constipated. No symptoms from other organs.

The patient was put to bed immediately and Dr. Lowbaugh, of Osceola, and Dr. Bob, of Calumet, were called in to see him. Microscopic examination of the blood showed the number of the white corpuscles seemingly increased; the red corpuscles were greatly changed with respect to size and form.

As there was no passage from the bowels a glass rod was introduced into the rectum of the patient, and a sample of the faeces taken in that way and put under the microscope showed a few characteristic eggs of the *Bothriocephalus latus*.

6th.—Kamala with honey was prescribed. The bowels moved in the night, but no worms were passed.

7th.—The condition of the patient is alarming; he is quite apathetic; hardly answers questions; vomits repeatedly, and only reluctantly swallows some milk. The pulse beats 140, the temperature is 104°.

I had but very little hope of his recovery, but the next day there was an apparent change for the better. He was sitting up in his bed, willingly took some food, was smiling, and said that he felt better. There was a movement of the bowels, but no more worm eggs were found by microscopic examination.

From this time the patient improved steadily, the

appetite and the strength increased every day, and within a week he was able to drive home again, feeling fairly well, although still somewhat weak and pale. There was no more fever, there was no dilatation of the heart, and no murmur to be heard.

Besides the anthelmintic, iron and arsenic pills had been prescribed together with absolute rest in bed, and the patient was ordered to continue this treatment for at least six weeks.

I was informed by letter of the 29th of January, 1896, that the recovery had been uninterrupted and that the patient was still very well.

## THE COURSE AND PROGNOSIS OF ORBITAL TUMORS,

AS INFLUENCED BY SURGICAL OPERATIONS FOR THEIR  
REMOVAL.\*

By CHARLES STEDMAN BULL, M.D.

For some years past the attention of the writer has been turned to a consideration of the prognosis of orbital tumors, whether primary or secondary, as influenced by surgical interference, with special reference to the frequency of return of the tumor and the rapidity of its growth. Such knowledge as the writer may have gained on the subject has come almost entirely from his own experience; for ophthalmic literature is well-nigh silent on the subject. None of the older authors make any reference to the matter, though all advocate early and radical operative interference. Of the more modern writers on the subject, there are but two who touch upon the question at issue at all, but they speak with no uncertain emphasis. Michel, in his *Lehrbuch der Augenheilkunde*, second edition, 1890, says: "The prognosis in these cases is always bad, even after surgical interference. There is great danger of an unfortunate quick return locally of the tumor with extremely rapid growth. When the tumor proceeds from one or more of the facial bones in the vicinity of the orbit, the bony walls of the latter are certain to be involved and the growth is correspondingly rapid."

Lawford, in the *Royal London Ophthalmic Hospital Reports*, vol. xii, in reporting a case of tumor of the orbit, in which five operations were followed by a return of the growth with increasing rapidity, and after the last operation by the rapid death of the patient, says: "An early and radical operation is too frequently followed by a return of the neoplasm and its rapid growth."

In considering briefly the increased rapidity of growth of malignant tumors of the orbit after surgical operations for their removal, it will be convenient to divide these tumors into three classes—viz.: 1. Tumors which primarily were infra-ocular and which had invaded the orbit secondarily. 2. Tumors which origi-

nated in the orbit, whether in the cellular tissue or in the periosteum of its bony walls. 3. Tumors which originated in the bones or sinuses adjacent to the orbit and involved the orbit secondarily.

1. *Primary Intra-ocular Tumors, which Involve the Orbit Secondarily.*—When an intra-ocular neoplasm has penetrated the sclera and involved the orbital tissue, or when it has extended backward along the optic nerve, the prognosis is invariably bad. This condition is sometimes recognized before enucleation of the eye, but more frequently is not discovered until after enucleation has been performed. In such a case there is no certainty that an operation, no matter how radical, will remove all the diseased tissue; and in a very large percentage of cases the growth returns in the orbit itself, or in some one of the sinuses or spaces adjacent thereto. Even complete exenteration of the orbit and removal of its periosteal lining does not prevent this, once the orbital tissue is involved. Indeed, it has seemed to the writer that the removal of the periosteum from the orbit hastened the return of the growth by depriving the underlying bone of its protective envelope.

2. *Tumors which Originate in the Orbit.*—In this second class, primary orbital tumors, malignant in character, in which the eyeball remains intact, or is involved secondarily and late in the course of the disease, the same unfavorable prognosis as to return and rapidity of growth must be made. Even when the orbital tumor appears to be encapsulated, experience proves that there is no certainty that some germs have not been left behind. Moreover, malignant growths in the orbit are very rarely encapsulated.

3. *Extra-orbital Tumors originating in the Bones or Sinuses Adjacent to the Orbit, and involving the Orbit Secondarily.*—This third class of cases embraces the most serious and desperate of all. The cavities and bones usually involved are the sphenoid and ethmoid. The nature and origin of these growths may often be diagnosticated in the beginning, as soon as orbital symptoms arise, and sometimes even before any such symptoms present themselves. The prognosis in these cases must be put down as absolutely bad from the beginning. No matter where the origin of the growth, all the deep bones of the face and their communicating sinuses eventually become involved. By emptying the sinuses and extensive exsection of the bones diseased, we do not succeed in arresting the progress of the malady, and experience has taught the writer that every operation in these cases tends to increase the certainty of return and the rapidity of its growth, and in so far shortens the life of the patient. Each operation, being of necessity the more extensive and severe, saps the strength of the patient and weakens his powers of resistance.

The tendency of these malignant tumors of the orbit, whether primary or secondary, is to grow forward or outward rather than inward or backward, and this fact probably explains why patients affected with such

\* Abstract of a paper read before the American Ophthalmological Society, July 15, 1896.

tumors live as long as they do, and why they usually die from general exhaustion, rather than from extension of the growth to the brain. It is the exception when these tumors cause death by extension to the brain, whether through the roof of the orbit, or through the optic foramen, or through the sinuses at the apex of the orbit.

The tendency to extension outward and forward of these tumors may perhaps also explain the increased rapidity of their growth after exenteration of the orbit, or after the more radical operation of exsection of the diseased bones. The empty orbit or the cavity left in the face by the removal of the diseased bones are free spaces toward which there is no resistance to the extension of the neoplasm; while backward or upward its progress is hindered by a bony wall of varying thickness, in which absorption goes on slowly, even when the periosteum has been removed.

These brief remarks and the conclusions which follow are based upon the histories of thirty-six cases, all taken from the private practice of the writer, as it has been proved that patients in private practice can be more satisfactorily followed up than those in hospital practice. All these cases have been watched from start to finish by the writer; and the course of the disease and the results of operative interference may be read in detail in the accompanying histories of the cases. In a much larger experience, extending over a period of twenty-five years of hospital service, the same conclusions have been forced upon the writer.

*Conclusions.*—1. The prognosis of all forms of malignant orbital tumors, whether primary or secondary, is unfavorable; and if the tumor is primarily in one or more of the deep facial bones or their sinuses, the prognosis is positively bad.

2. Except in the case of encapsulated tumors of the orbit, surgical interference is almost invariably followed by a return of the tumor; and the growth of the secondary tumor is more rapid than that of the primary lesion. With each succeeding operation, the period of quiescence in the return of the tumor grows shorter, and the rapidity of the growth increases.

3. The patient's family, and in certain cases the patient himself, should in the beginning be told of the serious nature of the trouble, and be warned that complete removal of all the disease germs is a well-nigh hopeless task. The burden of the decision as to surgical interference must rest upon the shoulders of the patient.

4. Repeated operations in these cases undoubtedly shorten the life of the patient. While it is therefore our duty to operate in all cases in order to relieve severe or unbearable pain, we should be slow to operate merely for the sake of relieving temporarily physical disfigurement or deformity, especially if we are convinced that by so doing we shorten the life of the patient, even if that shortened life is rendered more bearable to him.

## THE TREATMENT OF DISEASES OF THE NOSE AND EAR WITH OXYGEN GAS.\*

By GEORGE STOKER, M.R.C.P.L.

PRESIDENT OF  
THE BRITISH LARYNGOLOGICAL, RHINOLOGICAL, AND OTOLOGICAL ASSOCIATION,  
LONDON.

SOME two years ago I made a discovery with regard to the curative effects of oxygen gas on wounds, ulcers, and suppurating surfaces when they were exposed to its influence. It was but natural that I should endeavor to apply these more general surgical results to those special conditions in which we are together interested, and it is to give you some of the results of those endeavors that I venture to ask your kind permission to read this short paper:

The cases I selected to treat with oxygen gas were (a) "ozana," (1) syphilitic, (2) chlorotic, and (b) "chronic suppurative disease of the middle ear."

The method of applying the treatment is as follows; and I mention it now as the application to both nose and ears needs only one description. The oxygen is contained in a wedge-shaped bag made of mackintosh. This bag is placed between two boards (pressure boards), such as are used with the oxyhydrogen light. From this bag a tube leads, which terminates in a nose or ear piece. There are two taps—a large one on the bag, for the purpose of filling it, and a small one to regulate the stream of oxygen during treatment. This bag contains one cubic foot of gas, or of gas and purified air mixed in equal quantities, and this amount should suffice for six hours' treatment. In the great majority of cases I use equal parts of oxygen and purified air. This latter is prepared by being pumped by means of a bellows or hand ball through two wash bottles, the first containing some water and the second Condé's fluid. The bottles are attached to the bag for this purpose, and when the bag is half full it is then detached from the bottles and filled up with oxygen. The bag being filled, we are then ready to begin the treatment. The nose piece is passed into one nostril, the other nostril being plugged with cotton wool; the patient is directed to breathe through the mouth, the taps are turned on, and the treatment is begun. In ear cases the only difference is that the terminal piece is placed in the external auditory meatus, and in case of either ears or noses it is desirable to have several different-sized terminals to fit different-sized orifices. The oxygen should be allowed to pass into either the nose or ear from three to six hours daily. In nose cases it is best to use it about half an hour to an hour at a time, giving intervals of rest between the times. If used for more than an hour in nose cases it is apt to cause headache. The only additional treatment is using warm water to cleanse the parts during the day; the necessity

\* Read before the American Laryngological Association at its eighteenth annual congress.

for doing so seldom or often will, of course, depend on the amount of the discharge, but it must not be done less than twice daily.

I now give the notes of four cases—i. e., two of "ozæna" and two of "suppurative middle-ear disease." These are typically bad cases, and seem, I consider, to amply illustrate the results of the oxygen treatment:

CASE I. *Syphilitic Ozæna*.—Mrs. P., aged forty years. Had suffered from syphilitic ozæna for five years. Most of the internal parts of the nose had ulcerated away. The cartilaginous septum and turbinals had quite disappeared, and the inner wall of the right antrum was perforated and in an active state of necrosis. The nose was full of scabs or crusts, and the horrible stench characteristic of the disease was only too apparent. In the end of August, 1895, the oxygen treatment, as before described, was begun, and was continued for a month. At the end of that time her confinement was approaching and she had to leave the hospital. When she left, the ozæna was completely cured, neither smell nor crusts being apparent. In January, 1896, her condition of "wellness" was still maintained. Early in March she returned to the hospital and the condition of the nose was: the left nostril remained quite healthy, but the necrosis of the inner wall of the right antrum had progressed and extended and given rise to ozæna, but only on that side and in near proximity to the diseased bone. After a few weeks of oxygen treatment the diseased bone separated, and the patient once more was quite free from symptoms of ozæna.

CASE II. *Chlorotic Ozæna*.—A. B., aged nineteen years, had suffered for several years from ozæna. There was the usual smell, accompanied by the formation of crusts. The patient suffered also from dysmenorrhœa. She was treated with oxygen gas, as in the former case, and in three days the smell had quite disappeared, and she left in three weeks' time completely healed. In this case a remarkable feature was the change of color of the scabs produced by oxygen; from being of a deep brown color they became in a few days quite white.

In reference to these cases, it is fair to note that they had both had prolonged and varied treatment before the oxygen was tried, and in both instances had resisted all treatment: and in the first case it is evident that the good effect of the treatment was and is permanent, so far as the soft tissues are concerned, and it was only the existence of necrosis that caused a recurrence of the ozænic symptoms.

I may here state that I am now using oxygen in cases of purulent discharge from the accessory nasal cavities—i. e., the antrum and the frontal and ethmoidal cells. So far, the results have been satisfactory, and I hope to report them to your honorable association on another occasion.

CASE III. *Chronic Suppurative Middle-ear Disease*.—A. L., a girl, aged nineteen years, had suffered for twelve months from chronic discharge from the left ear; she had occasional pain, and was very deaf on that side. The membrana tympani had suppurated away, all except the anterior superior segment. On April 18, 1896, the oxygen treatment was begun, half a cubic foot of oxygen being used at intervals of half an hour during the day. On the 22d of April the discharge had practically ceased and only a little flaky mucus came from

the ear on syringing. There was no purulent discharge to be found. At the end of a week she was discharged cured, and it still remains to be seen how permanent the relief given will be.

CASE IV. *Chronic Suppurative Middle-ear Disease*.—J. G. Several years ago she had an attack of scarlet fever, and the discharge began in the second week. In the fifth week inflammation and pain set up behind the left ear. The mastoid was opened and a drainage tube put in. Afterward a dark-colored offensive discharge was most profuse from both ears, and continued more or less till the patient came under my care in November, 1895. During those seven years many and varied forms of treatment were tried and carefully carried out, but without success. The patient was under the care of a well-known London specialist.

On November 9th the oxygen treatment was begun, and was carried out about four hours daily. The improvement set in at once, and the offensive smell and discharge disappeared during the first ten days. The following are the notes of the conditions present when I first saw the patient:

November 1st. Hearing distance, watch: right ear, two inches; left ear, ten inches. Right ear, lining of meatus swollen and boggy. Profuse and most offensive discharge and constant pain. Glands below the ear swollen and painful. Large perforation of membrana tympani.

19th. Oxygen treatment has been used for about four hours daily, at intervals. Meatus healthy, swelling disappeared. Discharge and smell almost gone.

December 18th. No pain, swelling, or discharge. Hearing distance, watch: right ear, two feet; left ear, two feet. The ear was syringed with warm water twice daily, no other treatment being employed.

All these cases speak for themselves, and I am grateful for being allowed to bring the knowledge of this system, that I have been fortunate enough to originate, before the notice of the American Laryngological Association, as I feel sure that in the great home of modern progress it will have a fair and exhaustive trial, and that its being a new system will not be any bar to its acceptance if, when it is weighed in the balance, it is not found wanting.

#### REPORT OF

#### A CASE OF GONORRHOEAL ENDOCARDITIS.

By ALBERT ABRAMS, A. M., M. D.,

PROFESSOR OF PATHOLOGY, COOPER MEDICAL COLLEGE, SAN FRANCISCO.

It is now conceded beyond cavil that the *Gonococcus Neisseri* is the actual etiological factor in specific urethritis. The culture of this germ, and the production of gonorrhœa following its introduction into the healthy urethra without *lesio continui*, are facts which are no longer doctrinarian in import. Many of the visceral manifestations of specific urethritis have been demonstrated to be provoked by gonococcic metastases. This is true of the endocardium, pleura, and synovial membranes. It is more than problematical that the reported cases of multiple neuritis and dorsal myelitis sequential to gonorrhœa have been instigated by the

same cause. The question of mixed infection in the complications of gonorrhoea is in a measure solved by the accurate observations of Wertheim. The latter succeeded in obtaining pure cultures of gonococci in the pus of salpingitis and oophoritis. It can not be denied that other micro-organisms, notably those of suppuration, are concerned at times in the metastatic processes. Among the complications of gonorrhoea endocarditis is one of the most infrequent. Up to the present time but few authentic cases of gonorrhoeal endocarditis have been reported. Among the contributors of cases are Councilman, Winterberg, Schedler, Morel, Martin, Derignae, and notably Leyden. Among the cases reported, in most of them the endocarditis was preceded by gonorrhoeal rheumatism of the joints. All the cases occurred in male patients. The aortic valves were more frequently implicated than the mitral valve. Some of the cases ran a chronic course and terminated in recovery. Others presented the characteristics of malignant endocarditis and ended fatally. The endocardial complication in gonorrhoea may be a mere expression of pyaemic infection with localization of the septic material in the endocardium or dependent on unmixing infection from the gonococci alone. As a paradigm of pyaemic infection, the case reported by His may be cited. In this case septic thrombi had formed in the veins of the prostate and in the pubic plexus, leading to general infection and malignant endocarditis. Leyden, Wilms, and Councilman report cases of endocarditis where no organism other than the gonococcus was present in the endocardial lesions. The following case, which was seen in consultation with Dr. Dudley Tait, of this city, is presented as a contribution to the literature on gonorrhoeal endocarditis. It is to be regretted that no necropsy was permitted, although the tableaux of symptoms leave no doubt as to the correctness of the clinical diagnosis:

The patient, seventeen years of age, had been treated for about six weeks before coming under observation for pyuria, presumably of renal origin. The pus continuing in the urine despite remedial measures, other counsel was sought by the parents of the patient. It was elicited on inquiry that the patient had contracted gonorrhoea, which fact, prompted by fear, he did not communicate to his attending physician. This was his second infection, which remained untreated for about six weeks, up to the time that he came under observation.

An examination of the patient showed no disease of the thoracic viscera. There was an anterior and posterior urethritis with gonorrhoeal cystitis. There was no implication of the kidneys. No kidney elements were found in the sediment of the urine. The albumin present in the urine could be accounted for by the presence of the pus, as was conclusively shown by the accurate count method of Posner. Only the gonococci were demonstrated in the urethral pus. The urethra was narrowed four inches from the meatus, which fact necessitated the use of sounds to permit the passage of a moderate-sized soft-rubber catheter for washing out the bladder. Daily lavage of the bladder and urethra with a solution of permanganate of potassium was followed by a complete

disappearance of pus from the urine. The bladder symptoms likewise receded and the urethral discharge was reduced to a minimum. The latter at this time still contained gonococci, although diminished in number. On the fourteenth day, dating from the time he first came under observation, the patient had a chill, with a temperature of 103° F. Fulminating muscular pains were felt in the muscles of the shoulders and abdomen, and the patient vomited considerably. On this day an ill-defined tendosynovitis of the right tendo Achillis was present. On the following day the symptoms became aggravated. Tachycardia became distressing and a feeble systolic murmur over the aorta was heard; the area of superficial cardiac dullness was increased toward the right side. Petchial spots appeared all over the body and the exanthem was not unlike that of measles. On the subsequent day the patient felt a sudden pain in the region of the spleen. This organ was found to be enlarged and very painful on pressure (haemorrhagic infarction). The temperature persisted (104° F.), the sensorium became clouded, delirium was present, and the systolic murmur over the aorta became louder.

Symptoms on the following day: Petchia had developed into pustules and the exanthem resembled variola. Five large emboli were seen in the digital arteries at a point corresponding to the first phalanges of the third and little fingers; the terminal phalanges of the latter were gangrenous. On this day the patient died.

The character of the disease was unmistakable, although the absence of a post-mortem examination detracts materially from the scientific value of the case. The essential features of this case may be summarized as follows: Gonorrhoeal endocarditis, following an untreated specific urethritis at a time when the symptoms of the urethral lesion were retrogressing. The endocarditis was not preceded by gonorrhoeal rheumatism. The previous history of the patient was one of perfect health and absolute integrity of the heart. The absence of organisms in the urethra other than the gonococci warrant the assumption that the latter were alone concerned in the metastatic endocardial process.

431 GEARY STREET.

## THE RELATION OF ACUTE DISEASES OF THE NOSE AND THROAT TO DISORDERS OF DIGESTION.\*

By MOREAU R. BROWN, M. D.,

CHICAGO.

CLINICAL experience demonstrates that there are certain well-defined relations existing between acute inflammatory conditions of the nose and throat and other disordered organs of the body. In some cases these relations are easily explained; while in others they are shrouded in mysteries which pathology has as yet failed to unfold, and which all attempts to account for can be, at present, but matters of theory, not based on the result of completed scientific investigation. Not that

\* Read before the American Laryngological Association at its eighteenth annual congress.

the pathologist or laryngologist has been derelict in searching for the etiological relations, but rather that the limits of science have precluded their discovery. The connection between acute inflammation of the upper air-passages and disorders of digestion, although a matter of clinical observation, is no exception to this statement, and the surprising fact is that there is such a scant amount of literature bearing on the subject.

Bosworth, in his work on Diseases of the Nose and Throat, briefly refers to the changes occurring in the pharyngeal mucous membrane in stomacic disorders, and further calls attention to chronic inflammation of the upper air-passages as being an important etiological factor in acute inflammation of the same region. He considers the involvement of the pharynx in gastric disorders as due to the fact that the pharynx is a part of the digestive tract, being the point where the air-passages cross it, which may, in some cases, account for the extension of the inflammatory process.

In his Lettsomian Lectures, T. Lauder Brunton refers to stomach cough as being due to mild inflammatory changes in the upper air-passages, plus the digestive disturbances. He cites a case of stomach cough wherein the pharynx was decidedly hyperæmic, and although no laryngeal examination was made, it was concluded from the symptoms that the larynx was similarly involved. The cough and inflammation failed to respond to treatment until a blue pill had been administered. The following case, in my own practice, serves to illustrate the condition rather more forcibly:

Mr. —, aged about forty-five, restaurant keeper by occupation, a healthy, robust-looking man, fond of rich food, consulted me first about five years ago for a rather severe attack of acute inflammation in the upper air-passages (nose, pharynx, and larynx) accompanied with asthma. As a history, he stated that such attacks were generally preceded by gastro-intestinal disorders, and a few days previous to the present attack he had suffered considerable digestive disturbance, such as loss of appetite, disgust for food, nausea, headache, abdominal distress and pain, eructation of gas, constipation, and mental depression. The treatment directed to the inflammation of the upper air-passages was carefully carried out for a short time, but failed to give relief until a saline laxative, followed by such treatment as was calculated to restore the digestion, was ordered and taken. Afterward, appropriate treatment, carried on for some time, checked further asthmatic attacks, but I have seen him a few times since with acute inflammation of the upper air-passages which responds readily to remedies directed to the digestive organs.

I have searched the medical literature within my reach for other authorities bearing on this subject, and I am able to give the following reports:

Edema of the larynx in the angeioneurotic, connected with gastric disturbances generally, is mentioned by Collins, Osler, Lovett, and also by Pryor (*Med. Record*, July 28, 1894).

Nogano (*Currier méd.*, Paris, September 23, 1893)

records a case of hæmorrhage of the larynx in a forty-five-year-old man who had suffered from cirrhosis of the liver and cardiac disease.

Cackle (*Medical Times and Gazette*, August 4, 1884) records a case with symptoms resembling those of laryngeal phthisis. Later two attacks of unconsciousness followed in quick succession, the latter being fatal. At the autopsy, latent hepatic abscess was found, also a small ulcer of the left vocal cord, the nature of which was not stated. No signs of tuberculosis were discovered.

Ed. Löri (*Die durch anderweitige Erkrankungen bedingten Veränderungen des Rachens, des Kehlkopfs und der Luftröhre*, Stuttgart, 1885) thinks that "gastro-intestinal catarrh may be either the cause or the result of chronic throat and laryngeal catarrhs." He mentions also hæmorrhagic affections of the larynx in liver cirrhosis and echinococcus.

Ed. Löri (*Jahrbuch für Kinderheilkunde*, xxi, 1884; *Centralblatt für Laryngologie*, i, 360; *Orosi Hetilap*, 1884, No. 12; *Pest. med. Presse*, No. 31), speaking of gastric complications of laryngeal disease in children, says: "Laryngeal disease may affect the stomach by continuity, by swallowing secretions of ulcerated sores, cankers, etc., and gastric disturbances are often produced in a reflex way from the larynx. Especially do we frequently observe meteorism and anorexia with inflammatory disease of the posterior laryngeal walls, and also gastric dilatation and vomiting."

Turck has also recently demonstrated the bacterial origin of stomacic disorders from nasopharyngeal infection, finding similar micro-organisms in both regions, and the former relieved after relieving the latter. Further bacteriological research may be able to demonstrate the reverse of this position, and establish that stomach disorders are causal factors of laryngeal inflammations, though, as far as I can learn, no one has undertaken the task.

Steffin (von Ziemssen's *Cyclopadia*) says spasm of the glottis may be favored by elevation of the diaphragm, owing to overfilling of the stomach, or by overdistention of the intestines by fecal masses, or by serous swelling of the liver. Among the conditions found present in spasm of the glottis are swelling, and yellow or yellow-gray color of the liver, and a considerable deposit of fat within its cells.

Ariza (Madrid, Laringismo gastrico, *Centralblatt*, ii, 446; *El Distancier*, No. 44, p. 211, May 20, 1885) cites a case (Virchow's *Annalen*) of aphonia from indigestion relieved by an emetic. He distinguishes three varieties of laryngeal disturbance from gastric disorders:

1. Laryngeal hyperæsthesia, with normal aspect of the fauces and larynx, the patients complaining of burning sensations, pain, etc. All these patients suffer from dyspepsia. He reported cases at the Laryngological Congress at Milan.

2. "Laringismo gastrico plastico." The vocal cords and surroundings are hyperæmic and painful, and vary

with the gastric disorder. This form especially occurs with chronic gastric disease.

3. "Laringismo gastrico paralitico." He says that he can not explain the aphonia and dysphonia in cholera cases, except by a temporary reflex paralysis of the larynx. He finds, however, in the literature, no laryngoscopic observations, and thinks they would be difficult to make. Kispert, who abstracts his paper, says that Matterstock made some good observations of this kind in the Würzburg epidemic, and found this paralysis frequent, especially on the left side.

So much for authorities. The explanation of the conditions of the simultaneous occurrences is not easy, but the following may be suggested: In œdema of the larynx, occurring during the course of liver disorders, it is apparent that we must look to the obstruction of the portal circulation as a cause, and in the inflammation produced by the imbibition of alcohol rather to the venous stasis which follows its use. This is particularly the case in œdema of the upper air-passages ensuing upon a debauch, as shown by the rapidity with which it disappears on taking further liquor early the next day, and the subsequent increase of the œdematous condition, or by the more rapid recovery following an evacuation of the gastro-intestinal tract.

In acute catarrhal inflammation of the nose and throat, supervening on disorders of digestion, we have an entirely different element to deal with. In offering an explanation for this condition we must largely theorize. It has been, in times past, the custom to call to our aid the old theory of reflexes, and it may not be unreasonable to suppose that these views are not entirely without foundation. It is a recognized fact, as so aptly put by M. Gross (*New York Medical Journal*, May 4, 1895), that "every affection of the stomach is reflected back on the other organs; and inversely, every disorder of the organs reacts upon the stomach." Yet in the present day of bacteriological research, when the micro-organism theory of inflammation is generally recognized, we must agree with Bosworth, who, in a paper read before this association last year, states: "I think that as we become more familiar with the disorders of the upper air tract we shall in many cases be able to abandon this somewhat indefinite and obscure term 'reflex,' and adopt the theory that many of the so-called 'reflexes' are the direct result of morbid action upon either the nerve centres or the tissues involved in the inflammatory process" (*New York Medical Journal*, November, 1895, page 635).

What bacteriological research has failed to fully establish is demonstrated clinically—namely, that an acute inflammation of the upper air-passages will create disorders of digestion by direct infection through the mass of muco-purulent secretion, loaded with bacteria, which finds its way into the stomach. But, as to the reverse process, is it probable that the upper air-passages become inoculated directly by the stomach contents?

The irritation of the larynx and pharynx, or, less often, the nasopharynx, from the eructation of the contents of the stomach, is to be ascribed more to the direct irritant effect of the secretion than to inoculation. Yet the irritating effect may be so intense and prolonged that acute inflammation follows. In this case it may be that the secretion furnishes a proper soil for the bacteria which light up the inflammation.

J. E. Free (*New York Medical Journal*, December 7, 1895) states: "If there is a morbid process at work in the stomach, there will be established in it colonies of bacteria in abundance, the toxins may be absorbed, and nourishment to the tissues thus contaminated, and every tissue of the body compelled to feed on this contaminated blood."

Warren, in his *Surgical Pathology* (page 122), says: "Van Buren explains catching cold 'by arrest of the function of the skin as an emunctory, whereby certain effects, and presumably noxious materials which should be eliminated, are retained and act as blood poisons.' This view of auto-infection is used to explain any febrile and inflammatory disturbances due to ptomaine absorptions arising from gastric and intestinal disorders."

We know that the presence in the circulatory blood of certain toxic products of some micro-organisms favors the development of foci of inflammation, and the site of a chronic inflammation seems sufficient to predispose to infection. Orloff (*Materialien zur Frage über die Eintrittswege der Mikroben in den thierischen Organismus*, *Centralblatt f. Bacteriologie u. Parasitenkunde*, Bd. cxi, No. 15) fed pure culture of staphylococcus to six healthy animals. He then made a subcutaneous fracture in all six animals, and found that suppuration ensued at the point of fracture. This demonstrates that bacteria and toxins in the stomach will infect any weak point in the system. We may therefore surmise that in this manner the nose and throat may be infected through disorders of digestion. Another explanation of this condition might be that digestive disorders would lower the vitality to such a degree that the patient would become more liable than the healthy to attacks of acute inflammation, and this would be more apt to occur at points weakened by chronic inflammatory changes, such as we find in the upper air-passages of the majority of individuals.

There is one disease of the gastro-intestinal tract in which laryngeal complications have been extensively studied, and while typhoid fever may not be considered as falling within the scope of my subject, yet the inference is legitimate that if typhoid fever does produce laryngeal complications, so also may gastritis have an analogous influence on the larynx and other upper air organs.

Laryngeal complications occurring in typhoid fever have attracted no little attention, and literature abounds with reports of cases and theories advanced as to the relation they have to each other. The laryngeal changes

vary from a slight degree of hyperæmia to rather extensive loss of tissue. In some cases there is what appears to be a simple catarrhal laryngitis, or there may be œdema, infiltration of tissue, ulceration, or perichondritis. The larynx is, at times, left in a state of extensive deformity. The changes may occur at almost any stage of the typhoid period, occasionally ushering in the disease. Voltolini (*Archives of Laryngology*, vol. i) describes a case where a patient, after exposure to wet and cold, had a severe laryngitis; in the course of a few days regular typhoid fever set in, and, running its usual course, the laryngeal condition progressed rapidly to the stage of ulceration.

The laryngeal complications seem to bear no relation to the typhoid symptoms. The deeper tissues are seldom involved in the early stages of the disease; ulceration, œdema, and perichondritis occur in the latter stages or during convalescence, sometimes as late as two months after the onset of the disease (*Union méd.*, March 10, 1892). As may be surmised, the symptoms may be serious from stenosis, or from the dangers of necrosis. The condition, in some cases, may result in loss of life; tracheotomy or intubation may be required; and the resulting deformities may necessitate the indefinite retention of the tube. The lesions generally involve the epiglottis, arytenoids, and cricoid cartilages.

Lucatela (*Gazzetta degli Ospedali*, 70, 132) and others report finding Eberth's bacilli in the larynx in fatal cases. Brieger and Fränkel failed to demonstrate the presence of typhoid bacilli in these laryngeal ulcers (Kanthack and Drysdale, *Journal of Laryngology*, April, 1896), but the weight of evidence seems to favor the specific origin of laryngeal ulcers in typhoid. Taken alone, the argument from analogy is not convincing, but it seems to be plausible enough to infer that if the typhoid bacilli can infect the larynx, so may other forms of bacilli, which have their origin in the stomach, be able to invade and infect, likewise, the upper air-passages.

To sum up the subject, then, I would say that no proof has yet been presented of the direct causation of acute inflammatory processes in the upper air-passages by stomach disorders; but that clinical observation is abundant in favor of such causation, and that the hope may be entertained that the bacteriologists will soon be able to supply direct proof.

## Therapeutical Notes.

### The Treatment of Asthma Apart from the Attacks.—

In the *Revue internationale de médecine et de chirurgie* for July 25th we find an abstract of an article by M. Barié (*Thérapeutique appliquée* de Robin, 1896, fasc. viii) in which he gives the following formulæ for the treatment of asthma apart from the attacks:

1. Duclos speaks very highly of flowers of sulphur in

daily amounts of from eight to fifteen grains, to be taken before breakfast. The dose is to be continued for twenty consecutive days in every month for a period of six months, then for ten days of every month for a period of one or two years. This treatment appears to be more applicable to catarrhal asthma.

2. Arsenical preparations are appropriate in cases where the patient suffers with both herpes and asthma; the arsenic may be given in the form of Fowler's solution, in doses of from two to four drops at meals; in the form of granules, each containing 0.015 of a grain of arsenous acid, of which four a day may be taken; or in a liquid form as follows:

℞ Distilled water..... 9 ounces;  
Sodium arseniate..... 1.5 grain.

M.

A dessertspoonful of this is to be taken just before the principal meal.

3. The alkaline iodides are very efficacious. Green prescribed potassium iodide as follows:

℞ Decoction of polygala water (25 grains  
to 15 ounces of water)..... 3 ounces;  
Tincture of lobelia,  
Camphorated tincture of } of each..... 375 grains;  
opium,  
Potassium iodide..... 120 "

The dose is from two to three dessertspoonfuls a day.

The following antasthmatic elixir was formulated by Aubrée:

Take thirty grains of polygala root and four ounces of water; boil it until the quantity is reduced to two ounces. Filter this decoction and add the following:

Potassium iodide..... 225 grains;  
Syrup of opium..... 3.75 ounces;  
Brandy..... 2 "  
Tincture of cochineal..... enough to color.

Three dessertspoonfuls of this mixture are to be taken every day.

M. Huchard recommends this formula, which he has used for a long time:

℞ Distilled water..... 9 ounces;  
Potassium iodide..... 225 to 300 grains;  
Tincture of polygala, } of each.. 75 "  
Tincture of lobelia, }  
Extract of opium, } of each. 1.5 grain.  
Extract of hyoscyamus, }

M.

The dose is two dessertspoonfuls a day.

M. G. Sée thought that, in order to obtain a curative effect, the employment of an average dose of from thirty to forty-five grains of potassium iodide was necessary for months. M. Barié himself prefers the iodides in weaker doses as follows:

℞ Distilled water..... 3 ounces;  
Sodium iodide..... 30 grains.

M.

From two to three teaspoonfuls of this solution are to be taken every day.

M. Barth approves of the following formula:

℞ Distilled water..... 6 ounces;  
Potassium iodide, } of each 150 grains;  
Tincture of hyoscyamus, }  
Extract of opium..... 8 "

M.

A dessertspoonful of this mixture is to be taken on going to bed. In regard to M. Barié's formula, says the writer, it should be remarked that sodium iodide is less active than potassium iodide in asthma. In Barth's formula the quantity of the extract is larger, but it gives better results when administered in smaller quantities, such as three grains.

In order to avoid the disagreeable taste of the iodides in the liquid preparations, M. Barić has devised the following, which keeps perfectly:

- R Sodium or potassium iodide..... 2.5 grains;  
Bordeaux turpentine..... 0.75 grain;  
Crude opium..... 0.2 “

M.

This quantity makes one pill, and three such pills, coated with balsam of Peru, are to be taken every day.

It must be borne in mind, says the writer, that the iodide treatment is badly tolerated, and that, according to Trousseau and Potain, it rather aggravates the disease, especially in nervous persons. In regard to mineral waters, Pidoux recognized three elements in asthma: Nervous, catarrhal, and organic, and, according to the predominance of one or the other, arsenical, sodium-bicarbonate, or sulphur waters are indicated.

Finally, M. Huchard expresses the opinion that asthma, essential or nervous, is generally the result of an intoxication, which is nearly always alimentary. The diet of an asthmatic person, he says, is of the greatest importance, perhaps the principal point in the treatment of asthma apart from the period of the attacks. He recommends milk and vegetables, also a very small quantity of well-cooked meat.

**The Treatment of Stomatitis.**—In the *Nord médical* for August 1st the following formulae for various forms of stomatitis may be found:

*Aphthous Stomatitis.*—The ulcerations may be touched with a piece of absorbent cotton saturated with one of the following solutions:

1. Sodium salicylate..... 300 grains;  
Distilled water..... 3 ounces.
2. Sodium borate..... 45 grains;  
Sodium salicylate..... 75 “  
Tincture of myrrh..... 60 “  
Syrup of mulberries, } each..... 225 “  
Distilled water, }
3. Sodium chloride..... 90 grains;  
Cherry-laurel water..... 225 “  
Syrup of althea..... 375 “  
Decoction of poppy seeds..... 6 ounces.

The patient should take only boiled or sterilized milk.

*Erythematous Stomatitis.*—If the inflammation of the mouth is connected with the eruption of the teeth, frequent rinsing and spraying should be practised, especially after meals, with boric-acid water or the following solution:

- Sodium borate..... 30 grains;  
Sodium bicarbonate..... 60 “  
Distilled water..... 3 ounces.

If the inflammation appears during the course of the infectious disease, the following may be used:

- Boric acid, } each..... 30 grains;  
Potassium chloride, }  
Lemon juice..... 225 “  
Glycerin..... 300 “

Frequent washings with Vichy water or Vals water are also very good.

*Thrush.*—The prophylactic treatment consists in carefully cleansing the infant's mouth after each nursing with Vichy water. The curative treatment includes the same method of washing, and besides, frequent applications of the following:

- Sodium borate, } each..... 150 grains;  
Sodium bicarbonate, }  
Glycerin..... 600 “

At the same time it is well to institute gastro-intes-

tinal antiseptics, for which the following potion will be found useful:

- Bismuth salicylate, }  
Benzo-naphthol, } each..... 15 grains;  
Sodium bicarbonate, }  
Syrup of orange flowers..... 300 “  
Orange-flower water, } each..... 900 “  
Linden water, }

*Ulcerative Membranous Stomatitis.*—Potassium chloride is preferable in this form of stomatitis; it may be prescribed internally and externally. For the former, thirty grains a day may be given to a child from five to ten years of age, as follows:

- Potassium chloride..... 30 grains;  
Syrup of raspberries..... 300 “  
Julep of gum..... 2.5 ounces.

A dessertspoonful of this mixture is to be given every two hours. The following solution may be used for lavage and irrigation:

- Potassium chloride..... 75 grains;  
Honey of roses..... 450 “  
Distilled water..... 6 ounces.

To paint upon the ulcerations, the following is recommended:

- Potassium chloride..... 60 grains;  
Rose honey..... 150 “  
Glycerin..... 300 “

In rebellious cases tincture of iodine may be used in the following manner:

- Tincture of iodine..... 150 grains;  
Glycerin..... 300 “

Permanganate of potassium may be used as follows:

- Potassium permanganate..... 8 grains;  
Distilled water..... 2 ounces.

*Gangrenous Stomatitis.*—The local treatment consists in preventing the progress of the disease and in disinfecting the gangrenous region. The diseased parts should be cauterized with Paquelin's cautery, or with acid nitrate of mercury, or with pure nitric acid; in doing this the tongue and the teeth should be protected as much as possible. After cauterization, dry chloride of calcium may be applied and allowed to remain on for a few minutes and afterward thoroughly washed off. This treatment should be practised twice a day, also bathing three times a day with a strong decoction of cinchona. It is well, too, to touch the diseased parts several times a day with the following preparation:

- Naphthol..... 150 grains.  
Sodium sulphocinate..... 2.75 ounces.

During the interval the mouth should be washed out with water to which the following solution has been added in the proportion of a teaspoonful to a glass of water:

- Sodium bicarbonate, } each..... 15 grains;  
Saccharin, }  
Salicylic acid..... 60 “  
Alcohol..... 6 ounces.

It is very important to continue general treatment: the patient's strength should be kept up by the employment of nourishing food, such as milk, cream, meat soups, concentrated bouillon, and wines; extract of cinchona and cognac may also be used.

**The Vomiting of Appendicitis.**—The *Revue inter-nationale de médecine et de chirurgie* credits Pick with this formula:

- R Menthol..... 8 grains;  
Cognac..... 1½ oz.;  
Laudanum..... 5 drachms.

M. S.: Take from 10 to 20 drops several times a day, in a little sweetened water.

FRANK P. FOSTER, M. D.

NEW YORK, SATURDAY, AUGUST 29, 1896.

A GREAT PHYSICIAN OF THE SEVENTEENTH  
CENTURY.

It is good to see some attention given now and then to the memory of famous physicians who flourished two or three hundred years ago. Two examples have lately come to our notice. One of them is a series of articles on *The Therapeutics of the Old Masters*, by Dr. Fiesinger, published in the *Gazette médicale de Paris*. In the article published in that journal for August 1st he gives an account of Guillaume Baillou. The other, the only one that we have space to consider at greater length, is a short notice, in *Lyon médical* for August 9th, of a book on Baglivi, "the Sydenham of Italy," by Dr. Paul Fabre.

Although, says Dr. Fabre, Baglivi's name is not connected with any of the grand discoveries which immortalize man, his reputation has been perpetuated for nearly two centuries, not only in the medical schools, but in the profession. Baglivi, he says, had the true clinical method, which consisted in observing Nature simply without any preconceived notions or theoretical ideas, and conducting himself in accordance with this wise method of procedure.

He was born in Raguse, the capital of Dalmatia, on the 8th of September, 1668. His family, it is said, was of Armenian origin, but they moved to Italy and established themselves in Lecce, in Apulia. Perhaps, says the writer, there may be found in these conditions of atavism the explanation of the admirable readiness and ease with which he expressed his ideas which constituted the charm of his works.

After having received his classical education under the direction of a Jesuit, Michel Montaggio, Baglivi pursued his course of medical studies at Salerno, Padua, Bologna, and Naples. Afterward he returned to his native country, and visited in turn Venice, Florence, and Pavia, and finally settled in Rome, where he attained both wealth and fame. From the time of his arrival he connected himself with the two celebrated anatomists Pacchioni and Lancisi; he also met Malpighi, who was old and in bad health, and when Malpighi died Baglivi took charge of the autopsy. Afterward, according to the customs of the times, he conducted the autopsies of several cardinals and other dignitaries. Pope

Innocent XII, who esteemed him very highly, resolved to keep him indefinitely in Rome, and, in order to create a place which would be acceptable to a man of his worth, he removed Lancisi from the chair of anatomy and made him professor-in-chief of the medical clinic. The vacant place was then open for competition, and Baglivi obtained it after a very brilliant trial. Thus at the age of twenty-eight he found himself in possession of one of the finest scientific positions in the world, and in a very short time he justified the confidence that had been placed in him. In the same year he published the most important of his works, on the practice of medicine, and, says M. Fabre, it may be said that such a work on the art of healing had never been written before. Baglivi showed in these pages an extraordinary intellectual maturity, and the book excited a veritable enthusiasm. It was such a safe guide to good and sound practice as had never been known before. All the efforts of the young physician tended simply to restore the art of healing according to the precepts of Hippocrates, to profit by the experience of centuries, to free medical practice from hypotheses and theories which, each day, sprang into existence and vanished often after deluding the most capable men in the profession. This was the reason why he made closely observed facts the immutable basis of all rational medicine, and it is not surprising, says M. Fabre, that he was a believer in the theory of expectation in acute diseases and the declared enemy of revulsion by fly blisters and other violent medication.

Placed at the head of a scientific movement of his time, Baglivi enjoyed many honors. He was correspondent of the most celebrated academies, many pupils thronged to his lectures, and his patients included persons of the highest class. Unfortunately, his days were numbered. At the beginning of the autumn of 1705 he was attacked with an affection of the abdomen accompanied by ascites, to which he succumbed, after suffering a long time, on the 17th of June, 1707, at the age of thirty-eight.

THERAPEUTICAL AND PATHOGENIC PROPERTIES  
ATTRIBUTED TO THE RÖNTGEN RAYS.

PROFESSOR RÖNTGEN's great discovery was promptly followed by the conjecture that the X rays might prove to have remedial properties, but the notion was practically abandoned very speedily. Still, a French physician has recently reported a case of malignant disease in which, as he believes, the rays reduced the size of the morbid growth, although they seemed not to exert the least influence in warding off the fatal termination of the case.

On the other hand, some observers have lately put on record certain pathological phenomena that are thought to have been produced by the rays. So far as our knowledge goes at present, these morbid results seem to affect chiefly if not exclusively the skin and its appendages.

Dr. Marcuse (*Deutsche medicinische Wochenschrift*, July 23, 1896; *British Medical Journal*, August 15, 1896) relates the case of a lad, seventeen years old, on whom he experimented with the Röntgen rays once or twice a day for a period of four weeks; the sittings lasting from five to ten minutes, and longer when the chest was being illuminated. Hittorf's tube was sometimes placed close to the body and never more than eight or ten inches away from it. The heat from the tube is said to have been very slight. The lad was completely clothed when his head was undergoing examination, and wore his shirt when his chest was subjected to the apparatus.

At first a slight diffuse redness was observed in one half of the face, especially above the ear, with some desquamation. Subsequently there was a sharply defined area above the ear where the hair was very thin. The hairs could be plucked out without pain, and showed signs of degeneration—in short, there was incipient alopecia. There was pronounced injection of the conjunctiva of the eye that was situated on that side of the face that was affected. On the back there was a space "as large as a plate" over which the epidermis was completely separated, and the exposed corium showed hemorrhages and exudation. The patch was quite tender, but there had been no pain until shortly before the lesions were noticed. There were similar changes, but not so advanced, over a space of about the same size on the front of the chest. The dermatitis resembled that caused by a burn.

From other sources we hear of loss of the nails as a result of exposure to the X rays, and in the *Lancet* for August 15th Mr. William Rushton has a letter full of ingenious suggestion in which he cites Dr. Robert L. Bowles as having found that reflected luminous, or photochemical, rays, as well as the Röntgen rays, penetrate into the deep tissues and produce great and important changes. Mr. Rushton conjectures that ordinary sunburn, freckles, and the like are due to penetration by rays of light rather than those of heat. Evidently we have yet much to learn about the Röntgen rays.

### MINOR PARAGRAPHS.

#### THE STIGMATA OF DEGENERATION.

An article with this title, by Dr. Frederick Peterson, appeared in the July number of the *State Hospitals Bul-*

*letin* and has now been reprinted in pamphlet form. It deals chiefly with anomalies of the face, the teeth, the palate, the tongue, the eye, the ear, the limbs, the genitals, the skin, the motor function, the sensory function, speech, and the instincts or appetites. It is illustrated with a number of good cuts and shows a great amount of careful study on the part of the author.

#### COMPULSORY VACCINATION IN GREAT BRITAIN.

A ROYAL commission on vaccination which has been at work for seven years is on the point of making its report, which is said by the *Lancet* to contain a unanimous recommendation that amounts to an abolition of the compulsory clauses of the vaccination law. In our opinion, this action might have been taken long ago with advantage. The Anglo-Saxon spirit rebels against compulsion in such a matter, and doubtless the enforcement of the clauses alluded to has favored the antivaccination agitation.

#### THE ROYAL VICTORIA HOSPITAL, MONTREAL.

We learn by the *Montreal Gazette* that Lord Mount-Stephen and Sir Donald A. Smith, the founders of the hospital, have lately endowed it with securities of the par value of \$800,000, which it is expected will yield an annual income of \$40,000. To this fund is to be added the sum of \$250,000 remaining from the original gift of \$1,000,000 for construction and equipment.

#### ITEMS.

**Infectious Diseases in New York.**—We are indebted to the Sanitary Bureau of the Health Department for the following statement of cases and deaths reported during the two weeks ending August 25, 1896:

DISEASES.	Week ending Aug. 18.		Week ending Aug. 25.	
	Cases.	Deaths.	Cases.	Deaths.
Typhoid fever.....	56	11	25	6
Scarlet fever.....	11	2	18	2
Cerebro-spinal meningitis.....	0	0	1	1
Measles.....	47	6	53	5
Diphtheria.....	97	15	89	15
Tuberculosis.....	103	122	190	93

**The Neurological Section of the Pan-American Medical Congress.**—Dr. C. H. Hughes, honorary president of this section, is sending out the following invitation to the neurologists of the United States: "Can I rely upon you for a paper or subject of discussion for the Pan-American Medical Congress, to be held in the City of Mexico, November 16th, 17th, 18th, and 19th proximo? I have just been informed, rather tardily I think, of my selection as honorary president of the Section of Neurology and Psychiatry. The meeting promises to be an exceedingly profitable and agreeable one, socially and scientifically. We should make the best showing we can for American psychiatry and neurology. You can materially help in this laudable direction. Will you give me the promise of a paper and of your presence on the interesting occasion? If so, please indicate on the inclosed your intention to be present."

**A New Edition of Gray's Anatomy.**—It is announced by the publishers, Messrs. Lea Brothers & Co., that a revised edition of Gray's *Anatomy*, with several sections entirely rewritten and with many new engravings, will be published on the 1st of September.

**The Coney Island Hospital.**—An effort is being made in Brooklyn to equip the old Oceanic Hotel as an emergency hospital.

**Change of Address.**—Dr. S. Dana Hubbard, to No. 143 West One-hundred-and-third Street, New York.

**Army Intelligence.**—*Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from August 16 to August 22, 1896:*

MCELDERRY, HENRY, Major and Surgeon. The leave of absence granted him is extended two months.

A board of medical officers, to consist of BACHE, DALLAS, Colonel and Assistant Surgeon General, FORWOOD, WILLIAM H., Lieutenant Colonel and Deputy Surgeon General, HUNTINGTON, DAVID L., Lieutenant Colonel and Deputy Surgeon General, GANDY, CHARLES M., Captain and Assistant Surgeon, and REED, WALTER, Major and Surgeon, is constituted to meet at the Army Medical Museum Building, on Wednesday, September 23, 1896, at 10 o'clock A. M., for examination of candidates for admission to the Medical Corps of the Army.

**Naval Intelligence.**—*Official List of Changes in the Medical Corps of the United States Navy for the Week ending August 22, 1896:*

MCCORMICK, A. M. D., Passed Assistant Surgeon. Detached from the U. S. Steamer Bancroft and ordered to the Naval Academy.

SHIPP, E. M., Passed Assistant Surgeon. Detached from the U. S. Steamer Monongahela and ordered to the U. S. Steamer Bancroft.

**Marine-Hospital Service.**—*Official List of the Changes of Stations and Duties of Medical Officers of the United States Marine-Hospital Service for the Fifteen Days ending August 15, 1896:*

HUTTON, W. H. H., Surgeon. Granted leave of absence for twenty days from August 23, 1896. August 13, 1896.

SAWTELLE, H. W., Surgeon. Granted leave of absence for thirty days from August 23, 1896. August 13, 1896.

BANKS, C. E., Surgeon. To assume temporary command of the service at Vineyard Haven, Mass., for thirty days August 13, 1896.

BROOKS, S. D., Passed Assistant Surgeon. To assume temporary command of the service at Cleveland, Ohio. August 8, 1896.

WOODWARD, R. M., Passed Assistant Surgeon. Granted leave of absence for thirty days from August 13, 1896. August 11, 1896.

GREENE, JOSEPH B., Assistant Surgeon. Granted leave of absence for twenty-three days from September 14, 1896. August 13, 1896.

#### **Society Meetings for the Coming Week:**

**TUESDAY, September 1st:** New York Neurological Society; Buffalo Academy of Medicine (Section in Surgery); Elmira, N. Y., Academy of Medicine; Ogdensburg, N. Y., Medical Association; Syracuse, N. Y., Academy of Medicine; Medical Societies of the Counties of Franklin (quarterly), Herkimer (semi-annual), and Niagara (Lockport—quarterly), N. Y.; Hudson, N. J., County Medical Society (Jersey City); Androscoggin, Me., County Medical Association (Lewiston); Baltimore Academy of Medicine; Medical Society of the University of Maryland (Baltimore).

**WEDNESDAY, September 2d:** New York Academy of Medicine (Section in Public Health); Medical Microscopical Society of Brooklyn; Medical Society of the County of Richmond (Stapleton), N. Y.; Bridgeport, Conn., Medical Association.

**THURSDAY, September 3d:** New York Academy of Medicine; Brooklyn Surgical Society; Society of Physicians of the Village of Canandaigua, N. Y.; Obstetrical Society of Philadelphia; Cuyahoga, Ohio, County Medical Society.

**FRIDAY, September 4th:** Practitioners' Society of New York (private); Baltimore Clinical Society; St. Louis Academy of Medical and Surgical Sciences.

**SATURDAY, September 5th:** Clinical Society of the New York Post-graduate Medical School and Hospital; Manhattan Medical and Surgical Society, New York (pri-

vate); St. Louis Medical Society; Miller's River, Massachusetts, Medical Society.

## **Births, Marriages, and Deaths.**

### *Born.*

BAYNES.—In Troy, N. Y., on Tuesday, August 18th, to Dr. and Mrs. Joseph E. Baynes, a son.

### *Married.*

HENCKELL—ORPHY.—In Rochester, N. Y., on Wednesday, August 19th, Dr. Alfred William Henckell and Miss Ida Mary Orphy.

POOLE—SMITH.—In Providence, Rhode Island, on Saturday, August 23d, Dr. Louis Eben Poole and Miss Edith Louise Smith.

### *Died.*

COCHRANE.—In Montgomery, Alabama, on Tuesday, August 18th, Dr. Jerome Cochrane, aged sixty-four years.

GULEKE.—In Sheephead Bay, Long Island, N. Y., on Tuesday, August 18th, Dr. Hermann F. Guleke, aged seventy years.

HEWES.—In Stamford, Connecticut, on Sunday, August 16th, Dr. William J. Hewes.

KITTREDGE.—In Mount Vernon, N. Y., on Wednesday, August 19th, Dr. C. M. Kittredge, of Fishkill-on-the-Hudson.

McKNIGHT.—In Milwaukee, on Friday, August 21st, Dr. Lewis McKnight.

REYNOLDS.—In Suisun City, California, on Friday, August 7th, Dr. J. W. B. Reynolds, in the seventy-eighth year of his age.

## **Letters to the Editor.**

### **MEDICAL EDUCATION IN ILLINOIS AGAIN.**

CHICAGO, August 18, 1896.

*To the Editor of the New York Medical Journal:*

SIR: In your issue of August 15th Dr. J. W. Scott's communication in referring to my letter published in your *Journal* uses such expressions as "insincere motives," "perversion of facts," "venomous attack," and a multitude of other personalities, but not a single one of my statements has the secretary of the Illinois State board attempted to refute.

The doctor starts out with ". . . the fact that Dr. Grinker connected himself with and remained for a year upon the faculty of this school must, in the minds of fair-minded members of the profession, raise some question as to the sincerity of the motives which prompt his sudden solicitude for the cause of medical education," and he attempts by this to arouse prejudice against my statements instead of trying to disprove them.

The history of my connection with Harvey is as follows: After having read in the papers that the Illinois State board of health had decided to recognize the Harvey School of Medicine, I allowed my name to be used in connection with a professorship. I was invited to the college, and the secretary offered me the chair of pathology, which I accepted. Previous to my acceptance I had several conversations with the secretary in regard to the scope of the institution, its work, and its ultimate future, from all of which I gathered the remarkable admission that this school was only intended to be a preparatory school, a so-called "feeder" for the

day schools of medicine, and that it was expected that some day one of the regular day schools would buy up the night school and amalgamate with it. She assured me on a later occasion that her *senior class* was virtually useless, that none of the members of the class had a right to graduate, and it was not intended that they should. I then reasoned: Are there not reputable physicians teaching popular physiology and chemistry in the New York evening high schools, and why should I not connect myself with a preparatory school of medicine?

And here comes the most interesting part: As long as I was only teaching pathology to juniors I had no idea of the mental calibre of the seniors, who never were juniors in this institution and some not in any; but when my colleague, the regular professor of practice of medicine, temporarily discontinued his course of lectures, I had ample opportunities in my quizzes and lectures before seniors to form a correct estimate of the composition of the class.

Imagine my surprise when at the end of the term I received a note to come down to the office and sign diplomas! About the same time I was informed that students would graduate as full-fledged doctors, and eight diplomas were presented to me for my signature as the professor of pathology. I asked for credentials which would show that those eight seniors had passed in my branch with some reputable teacher, but was told that the directory was well satisfied that the students had passed in pathology somewhere. I then stated that I should not attach my signature to any of those diplomas until I had satisfied myself that the holders of them had passed in my branch. The secretary then told me that students might produce credentials if they saw fit to do so, but that they would graduate anyhow; furthermore, that such a request on my part was unheard of, and I was the only one of the faculty asking for credentials.

It was at this time that I discovered a *diploma-mill*, and I hastened to resign my professorship immediately, and who would not?

Now, if anybody raises a question as to the sincerity of the motives which prompted my sudden solicitude for the cause of medical education, he must be either blind or else indifferent to the best interests of our profession. What I did then was what every honest man would do. I tried to see the secretary of the State board of health, but failed to meet him. I informed the secretary's assistant of the object of my visit.

On the evening of the same day I met Dr. Scott, and asked for an investigation of Harvey Medical College.

Never was I more surprised than when Dr. Scott, whom I saw for the first time, answered all my objections in almost the same words that the secretary of the college had made use of the previous day. He knew by heart the name of every graduate of Harvey College, and was armed with an array of arguments that were simply astounding.

Does any one of my readers attribute this intimate acquaintance with the inside workings of Harvey College to sight-seeing or, perhaps, to supernatural powers?

In another interview between Dr. Scott and my colleague, the former professor of the practice of medicine at Harvey, who had also resigned because students were graduated who failed to pass the examinations in his branch, the secretary's partiality to Harvey was made still more manifest.

When the State board of health met, my colleague and I appeared against Harvey Medical School. A sys-

tematic effort was made at that meeting to prevent the reading of my charges, and only after I had made a strong plea for the privilege of the floor, in which I was assisted by the best men on the board, was I allowed to read my charges. Dr. Scott was exceedingly anxious to give the directors of Harvey—who appeared at the meeting by special invitation from the secretary—a hearing to defend their side of the question, although his motion to refer the charge to a committee had been carried.

My charges went to the committee, where they were buried, but not without my attending the funeral, which took place some time after my letter was published in this *Journal*.

That Dr. Scott is indulging in glittering generalities whenever he defends the board—or rather himself—and that he uses the bitterest personalities whenever he refers to me, can be learned from the following statements: "... No one acquainted with any of these members (and they are not unknown to the profession) believes that they would stretch the law in the interest of any institution, or that they are less jealous of the good name and high standing of the Illinois State board of health than the gentlemen who from whatever motives and without any knowledge of the workings of the board made such an unwarranted attack. That the policy of such a board could be molded by its clerical officer is unworthy of any consideration whatever."

Those members of the board who are known outside of their city have always been in a hopeless minority; the proportion is as 2 is to 7.

That the policy of such a board is molded by its clerical officer is a fact well known to everybody. I only need to mention Dr. John H. Rauch's name. That the secretary of the board is the most powerful person on the board is a result of its peculiar organization. The secretary is the only salaried officer of the board. The members of the board meet quarterly or semi-annually, have a friendly chat, and pass upon questions that the secretary has worked out very minutely—for this is his principal business—and then depart for their respective homes to meet again in three months.

As for not knowing the workings of the board and its committees, let the reader carefully peruse the following true report of a committee meeting called to investigate my charges against Harvey Medical School, and he will soon know how the board works.

One day I received a telegram from the secretary to appear before the committee on the medical practice act, before whom my charges against the Harvey night school were to be investigated. Another telegram reached me on the day of the meeting, in which I was requested to have with me the former professor of the practice of medicine at Harvey.

Armed with an amount of incontrovertible evidence and witnesses to prove beyond a shadow of doubt that the Harvey night school had violated almost every clause of the medical practice act, my colleague and I proceeded to the meeting-place.

This is what took place at the meeting, and the veracity of the following account can be attested by the witnesses who were with me:

After a preliminary sort of cross-examination carried on by Dr. Scott, in order to make my colleague, a very much respected physician, and myself appear in a bad light, the chairman of the committee declared the meeting in order. There was only one member of the committee present. Two constituted the majority. The first thing in order was the reading of my charges. Then,

without discussing them, or giving any of my witnesses an opportunity to speak, the chairman asked the secretary to read my letter published in your *Journal* of July 25th. I objected to the reading of the letter as being foreign to the object for which this meeting was called, and said that my charges were specific enough in themselves not to require any outside help to a proper understanding of the case.

The chairman, a good-natured looking German gentleman, shouted out: "*Nein*, you have *noddings* to say!" and the reading was continued. The secretary also volunteered the reading of an editorial item regarding the State board of health, published in your *Journal*, and this is how the investigation was concluded:

The chairman held up the copy of your *Journal* containing my letter and asked: "Are you the father of this article?" I answered in the affirmative. "Then," he continued, "I declare the charges against Harvey Medical School dismissed, because you have insulted the State, and it is now between you and the State." I attempted to reply that I had not even had a hearing, and that I had more than the necessary proofs to substantiate my charges, but was cut off. This is the manner in which serious charges were investigated, and I leave it to the judgment of thinking men to decide by whom such a policy could possibly have been molded.

Again, Dr. Scott sounds his own trumpet when he remarks that midwives are now required to pass a rigid written examination, instead of the oral examination previously conducted. It must be admitted that a wholesale plucking of midwives has taken place lately; it is possible that these plucked midwives will soon seek the portals of Harvey's side-show, the Playfair School of Midwifery, which I presume the secretary refers to in the following statement: "On the contrary, the secretary has been and is in favor of requiring all applicants for midwifery certificates to pass a rigid written examination" (before the faculty of the Playfair School?) "and . . . does advocate the fixing of the minimum requirements for schools of midwifery as high as those for medical colleges" (the Harvey, for instance?).

Dr. Scott's specialty seems to be *suggestion*, not only to the Harvey school, but also to the State boards of Iowa, Missouri, etc. But suggestive treatment has not been established on a firm basis as yet, and charity always begins at home.

The secretary states that the board does its work courageously, and here is where he struck the keynote. It certainly does have the unparalleled courage to recognize mushroom schools of medicine and then defend them. All praise be due them for this courageousness; as for myself, I should prefer to possess a little less courage in defending such institutions. The most amusing part of Dr. Scott's statements is to be found in his postscript, where he tries to enlist our sympathies for his vigilance in giving the Illinois Health University over to the attorney-general.

The *Chicago Record* of July 8th contains the following: "Dr. Scott, secretary of the State board of health, during the last month has received *hundreds* of letters from persons in different parts of the country complaining that they had paid J. A. Armstrong, of the Illinois Health University, of Chicago, money for diplomas to practise medicine. They found that the diplomas were valueless, as they would not be recognized by any State board of health. Dr. Scott said: 'The school is a chartered concern, and under the law any person can start a school of the kind. We have no power to suppress it

We answer all the letters by saying that the institution is a fraud.'"

It seems that something could be done after all, and I give the secretary his due for having been so vigilant as to have the charter of a diploma-selling concern revoked after it had sold diplomas to hundreds of farmers.

The foregoing reply would under no circumstances have been forwarded had not the board allowed their secretary to act and speak for them.

JULIUS GRINKER, M. D.

#### MENSTRUATION AFTER OOPHORECTOMY.

DURHAM, N. CAROLINA, July 10, 1896.

To the Editor of the *New York Medical Journal*:

SIR: On reading an article entitled A Case of Double Ovariectomy followed by Pregnancy and Delivery at Term, published in the *New York Medical Journal* of the 13th of June, 1896, a very peculiar case I have on record came to my mind. A year and a half ago I performed a laparotomy on a widow for fibroid tumors of an ovary. On finding the uterus also with fibroid degeneration, I amputated it, leaving only the cervix. Two months after the operation she began to menstruate, and has continued, though irregularly, till the present time. Both ovaries were removed, I am positive.

J. Y. GONZALEZ, M. D.

#### A SPLINT FOR THE ELBOW.

NEWMARKET, ONTARIO, August 17, 1896.

To the Editor of the *New York Medical Journal*:

SIR: In the August 15, 1896, issue of the *New York Medical Journal* there was a description of a new splint for use in the treatment of injuries of the elbow joint. In connection with injuries of the same region, I wish to give a description of a splint that might be more serviceable in a certain class of cases than the one previously mentioned, for example, where there is great injury or destruction to the joint, or to the parts entering into its formation, where perfect fixation of the joint is required for some time.

Its advantages are: (a) simplicity in its general make-up and application, (b) perfect immobility to the parts while placed at any required angle of flexion, (c) and at the same time perfect freedom in dressing the wound or observing untoward signs without disturbing the position of the injured parts. This form of splint is particularly applicable to the kind of injury previously mentioned to the joint where early passive motion is not advisable.

The description of the splint and its application is contained in the history of the following case:

W. P., a farmer's son, fifteen years old, family and personal history good. On February 8th, he was cutting feed with a straw cutter, and, as the material was not going through properly, he gave the wheel several quick turns, then ran round to raise up with his right hand the pin that compressed the straw, and in so doing stuck his elbow in the way of the large wheel.

*State on Examination.*—A clean cut four inches in length, fairly over the posterior and lower surface of the right elbow joint, directed from above and behind obliquely downward and forward, chipping the lower extremity of the humerus, and opening the joint cavity by separating the epiphysis of the ulna from its shaft. The olecranon process was drawn up two inches by the contraction of the triceps muscle. The nerve trunks were intact, and only a few anastomotic arteries were cut.

*Treatment.*—The patient was placed under the influence of an anæsthetic by Dr. Bentley, of Sutton. The olecranon was drawn down to position and united to the shaft by a silver-wire suture, a common old-fashioned table fork being used in the absence of a bone drill, and proving a worthy substitute in this emergency in the country. The drainage-tube had to pass between the coapted surfaces of bone into the joint cavity, and for this reason they could not be brought close together by the silver wire. The external wound was closed with silk sutures and dressed with moist bichloride dressing.

The joint was placed at rest in a position a little more than a right angle, the forearm supinated, and fastened to a splint contrived to suit the demands of the case.

The splint consisted of (a) a triangular web of thin board with the obtuse angle fitting into the angle of the elbow. The sides of the web running away from the obtuse angle were placed one on the supinated forearm, the other on the anterior and inner aspect of the arm. (b) Taking the obtuse angle as a centre, an arc of a circle was cut out, thus allowing room for dressing the elbow while the splint was in position. (c) Two padded strips 1½ inch wide were nailed on the sides of the web that came in contact with the arm and forearm. (d) On these two padded surfaces were fastened strips of rubber adhesive plaster by which the splint was fastened to the arm.

For the first ten days following, the temperature was between 100° and 102.6° F.; but, on my probing and syringing out the joint cavity every day with an antiseptic solution, the temperature soon became normal, and the wound, which had failed to unite by first intention on account of tension, began to assume a healthy appearance. Twenty-one days after the operation the silver suture was found loose and taken out. There had been complete union, ossific in its nature, between the epiphysis and the shaft. The wound was completely healed by March 1st.

*Result.*—The patient has perfect use of his arm for all kinds of heavy and light work. There is power of extension of only about twenty degrees, but flexion, supination, and pronation are excellent.

J. H. WESLEY, M. D.

#### BALSAM OF PERU IN THE TREATMENT OF SCABIES

BARNESVILLE, GEORGIA, August 18, 1896.

To the Editor of the New York Medical Journal:

SIR: Permit me to say in reply to Dr. S. E. Campbell's letter of June 9th, concerning balsam of Peru in the treatment of scabies, which appeared in your issue of July 18th, that there is evidently a discrepancy between the respective editions of Waring's *Therapeutics* consulted by us. My edition is the fourth American, published in 1886 by P. Blakiston & Ives, Philadelphia. In this edition he nowhere mentions balsam of Peru in scabies, but does state, on page 225, paragraph 859, the following:

"As a remedy for *Scabies in Children*, Dr. Monti, of Vienna, employed the balsam of copaiba in twenty-seven instances, and in each effected a complete cure. Each child was first washed with soap and water and then rubbed all over twice daily with the balsam. No other application was used. He found that the itch insect could not live in the balsam beyond two or three hours."

The question remains, Which edition is correct and which of the two balsams is the remedy for the itch?

Were it not for these peculiar political times I would venture to say to Dr. Campbell that our controversy reminds me of the story of the shield set up at the meeting of two paths, one side of which was gold the other silver, but, as I do not know how he stands on the burning issue of the day, I hesitate to intimate which side he has been gazing at in this question.

G. A. COGGESHALL, M. D.

### Proceedings of Societies.

#### AMERICAN LARYNGOLOGICAL ASSOCIATION.

*Eighteenth Annual Congress, held in Pittsburgh, Pa., Thursday, Friday, and Saturday, May 14, 15, and 16, 1896.*

The President, Dr. WILLIAM H. DALY, of Pittsburgh, in the Chair.

**The President's Address.**—(See page 33.)

**Spindle-celled Sarcoma of the Nasal Passage.**—Dr. J. E. BOYLAN, of Cincinnati, read a paper on this subject. (See page 43.)

**Tracheal Stenosis.**—Dr. SAMUEL JOHNSTON, of Baltimore, read a paper on this subject. (See page 45.)

**Intermittent Dysphonia Spastica.**—Dr. F. I. KNIGHT, of Boston, read a paper on this subject. (See page 47.)

**Some Remarks on the Principles of Treatment of Simple Acute Laryngitis and Bronchitis.**—Dr. THOMAS HUBBARD, of Toledo, Ohio, read a paper with this title. (See page 81.)

**The Prophylaxis of Nasal Catarrh.**—Dr. CARL SEILER, of Philadelphia, read a paper on this subject. (See page 83.)

**Some Observations in Laryngeal Tuberculosis.**—Dr. S. OAKLEY VANDER POEL, of New York, read a paper on this subject. (See page 84.)

**Some Remarks on Acute Disease of the Lingual Tonsil.**—Dr. H. L. SWAIN, of New Haven, Conn., read a paper with this title. (See page 111.)

**The Treatment of Atrophic Rhinitis.**—Dr. W. P. PORCHER, of Charleston, S. C., read a paper on this subject. (See page 287.)

Dr. CARL SEILER, of Philadelphia, said: My experience has been that the Gottstein cotton tampon is the only reliable method of alleviating the suffering of atrophic rhinitis. I do not think it has been borne out that there is any earthly use in saturating the cotton with anything. The mechanical irritation of the cotton is sufficient to produce supersecretion as well as lachrymation. The accumulation of moisture which takes place supplements the lost power of the nasal organs in moistening the air. I have tried a slight modification of the cotton tampon by substituting aseptic wool for the cotton. These experiments have satisfied me that the wool is not absorbent and does not produce the same satisfactory results that the cotton does. The cotton will absorb the moisture and filter the air as it is inhaled. As a rule I order my patients to wash out with an antiseptic solution (alkaline) and introduce the cotton tampon themselves. They wrap the cotton around a knitting needle, then pull it off and put it into the nose. I think this not only avoids the irritation produced by a foreign body but moistens the air as well.

stops up the large spaces, and is thus good in absorbing scabs.

Dr. THOMAS HUBBARD, of Toledo, Ohio, said: The ultimate purpose of all treatment is to render the glands aseptic, and check fermentation within the membrane. To this end I have found that cotton, saturated in an alcoholic solution of acetanilide and dried, inserted with the Gottstein tampon, is very useful. The atrophic turbinates can be wrapped in this cotton and all depressions carefully packed. I have seen two cases apparently cured, the atrophic areas being confined to the turbinates, and I am positive of beneficial results in other cases.

Dr. GEORGE A. LELAND, of Boston, said: In the treatment of atrophic rhinitis there are two principles which must be absolutely insisted upon—viz., antiseptis and stimulation. The first is obviously necessary and requires no elucidation. As to stimulation, we use the Gottstein or other packing, with the application of iodine on swabs, etc., to bring about hyperæmia, that is, more blood for nutrition in the part which has lost its nutrition from the extreme opposite state.

Now, there is a drug which in my hands has been eminently satisfactory, and has produced far better effects than any I have previously used or seen described. It is a drug the use of which we all condemn in the nose and upon mucous membranes in general; first, because of its systemic effect; and secondly, because of the secondary congestion brought about by it; but it is the use of it in hyperæmic or hypotrophic states, and especially in the hands of the patient, which we condemn. It is just this secondary hyperæmia which is most useful in these cases of atrophic rhinitis. It is my custom to place a thin pledget of cotton saturated with a 10- to 20-per-cent. solution of cocaine upon the remains, or upon the previous location of the lower turbinated bodies; for these are not always absent, that is, as to their third or cavernous layer, even when they appear so. These pledgets are allowed to remain for twenty or thirty minutes, when the full constrictive effect of the drug has been produced. They are then removed, and the nostrils are packed with large pledgets of some antiseptic solution—such as corrosive sublimate, 1 to 5,000 or even 2,000, or some of the other antiseptic solutions which are now being introduced. These are allowed to remain for about the same length of time. On their removal there will be, I am often astonished to find, a degree of hyperæmia in the regions of the turbinates which makes them seem to have been partially restored.

The patient is not allowed to make these applications, but comes to my office two or three times a week to have it done. The patient, however, uses an antiseptic spray or douche, together with the internal exhibition of some iodide (syrup of hydriodic acid usually), these agents seeming to produce hyperæmia in the upper air-passages.

My attention was called to the use of resorcin in cocaine solutions some years ago in my reading: I am sorry I have forgotten the author's name. I have used three or four grains to the ounce of the cocaine solution, and for two or three years I have very rarely had any systemic effect. The resorcin preserves the solution from deterioration also.

By the above-named method of treatment, I have been astonished to see cases which were apparently hopeless, after treatment lasting over many years in other hands—by the use of cauterization, strong solutions of nitrate of silver, and all the other methods which we

have used for this *bête noire* in our specialty—restored to such a condition that the patients considered themselves cured after a season of two or three years' treatment (summers excepted), which is a comparatively short time for the cure of such a condition.

Dr. M. J. ASCH, of New York, said: After using many different methods I have come to the conclusion that we can not do more for these patients than to thoroughly cleanse the parts and use a mild application—a mildly stimulating solution, bringing on reaction, is all that is necessary. Putting cotton in the nose accomplishes very little more than, if as much as, the cleansing and applications. It gives the patient trouble and the prognosis is no better. Individual cases require individual treatment. Perhaps the diminishing of the size of the middle turbinated bone may be required, but in ordinary cases thorough washing and stimulation will accomplish all that can be done.

Dr. JOHN O. ROE, of Rochester, N. Y., said: In the treatment of atrophic rhinitis I have had excellent results from the use of a mild solution of nitrate of silver applied thoroughly to the diseased parts, after thorough cleansing, followed by the use of a mild galvanic current, the negative pole applied to the interior of the nostril by means of a copper wire wound with cotton, moistened with a saline solution. The combined stimulating properties of the silver and the galvanic current have in many cases given me the most excellent results. I believe, however, that many cases regarded as ozena are simply the fetid secretions from some of the accessory sinuses drying into crusts in the nose. This readily accounts for the reappearance of fetid crusts on an apparently unabraded surface very shortly after the nose has been thoroughly cleansed and all crusts and secretions have been removed. In these cases the treatment is of no avail unless we reach the seat of the disease, which is frequently to be found hidden away in the recesses or cells and sinuses that communicate with the nasal passages.

Dr. JOHN N. MACKENZIE, of Baltimore, said: I do not think this discussion should close without a mild protest against the incautious and constant use of cocaine in the nasal passages and throat. As I pointed out years ago, aside from the possible dangers from the toxic effects of the drug, and the acquisition of the cocaine habit, the constant use of cocaine begets a permanent congestion of the parts which neutralizes all attempts to recover the normal condition of affairs. To treat, therefore, any chronic affections of the mucous membrane with cocaine is, to say the least, an injudicious and hazardous experiment.

Dr. J. E. H. NICHOLS, of New York, said: I should like to suggest the use of orthochlorophenol in these cases. It is a disinfectant and stimulates secretions very markedly. I have had better results with this than with anything else. A strength of ten per cent. is about right.

Dr. E. FLETCHER INGALS, of Chicago, said: I agree with Dr. Mackenzie that cocaine should not be used in any case unless the doctor knows just how much the patient is using and is in position to stop it at once if necessary. In these particular cases there is undoubted benefit to be derived from this drug, and if the patient does not use more than one or two grains in a week it may do good and no harm. I have seen the turbinated bodies restored under continuous use of small quantities of cocaine. Much benefit may be derived from the use of mercurials in these cases. A quarter of one per cent. of yellow oxide of mercury in powder is a good remedy.

A person approaching thirty-five is apt to get over the affection any way, but in younger people it is not so. The treatment should be cleanliness first, then oily sprays and small quantities of cocaine, and finally yellow oxide of mercury, in powder, once or twice a day.

(To be continued.)

## Miscellany.

**The American Public Health Association.**—The twenty-fourth annual meeting will be held in Buffalo, on September 15th, 16th, 17th, and 18th, under the presidency of Dr. Eduardo Licéaga, of Mexico. The following subjects will be discussed: The Pollution of Water Supplies; The Disposal of Garbage and Refuse; Animal Diseases and Animal Food; The Nomenclature of Diseases and Forms of Statistics; Protective Inoculations in Infectious Diseases; National Health Legislation; The Cause and Prevention of Diphtheria; The Causes and Prevention of Infant Mortality; Car Sanitation; The Prevention of the Spread of Yellow Fever; Steamship and Steamboat Sanitation; The Transportation and Disposal of the Dead; The Use of Alcoholic Drinks from a Sanitary Standpoint; The Centennial of Vaccination; The Relation of Forestry to Public Health; The Transportation of Diseased Tissues by Mail, and The River Conservancy Boards of Supervision.

The special committees are: *Publication Committee.*—Dr. Irving A. Watson and Dr. Granville P. Conn, of Concord, New Hampshire; Dr. Samuel W. Abbott, of Wakefield, Massachusetts.

*On the Pollution of Water Supplies.*—Major Charles Smart, U. S. Army, of Washington, with authority to select associates.

*On the Disposal of Garbage and Refuse.*—Mr. Rudolph Hering, C. E., of New York; Professor Delos Fall, of Albion, Michigan; Dr. Louis Laberge, of Montreal; Dr. Henry F. Hoyt, of St. Paul; and Mr. Roberto Gayol, C. E., of Mexico.

*On Animal Diseases and Animal Food.*—Dr. D. E. Salmon, of Washington; Professor James Law, of Ithaca, N. Y.; Professor José Gomez, of Mexico; Dr. Henry N. Avery, of Minneapolis; and Dr. Carl Weidner, of Louisville, Kentucky.

*On Nomenclature of Diseases and Forms of Statistics.*—Dr. Samuel W. Abbott, of Wakefield, Massachusetts; Dr. Jesus E. Monjaras, of San Luis Potosi, Mexico; Dr. Elzéar Pelletier, of Montreal; Professor Cressy Wilbur, of Lansing, Michigan; and Dr. Charles N. Hewitt, of Red Wing, Minnesota.

*On Protective Inoculations in Infectious Diseases.*—Dr. C. N. Hewitt, of Red Wing, Minnesota; Dr. George M. Sternberg, U. S. Army, Washington; Dr. George H. F. Nuttall, of Baltimore; Dr. M. Carmona y Valle, of Mexico; and Dr. William C. Bailey, of Knoxville, Tennessee.

*On National Health Legislation.*—Dr. Henry P. Walcott, of Cambridge, Massachusetts; Dr. J. N. McCormack, of Bowling Green, Kentucky; Dr. Irving A. Watson, of Concord, New Hampshire; Dr. James D. Plunkett, of Nashville, Tennessee; Dr. Henry B. Baker, of Lansing, Michigan; Dr. Samuel R. Oliphant, of New Orleans; Dr. Richard M. Swearingen, of Austin, Texas; Dr. Henry B. Horlbeck, of Charleston, South Carolina; Dr. Benja-

min Lee, of Philadelphia; Dr. Samuel H. Durgin, of Boston; Dr. U. O. B. Wingate, of Milwaukee; Dr. Stephen Smith, of New York; and Dr. C. O. Probst, of Columbus, Ohio.

*On the Cause and Prevention of Diphtheria.*—Dr. J. J. Kinyoun, U. S. Marine-Hospital Service, Washington; Dr. Peter H. Bryce, of Toronto, Canada; Dr. Juan Ramirez de Arellano, of Mexico; Dr. Wyatt Johnston, of Montreal; and Dr. A. W. Suiter, of Herkimer, N. Y.

*On the Causes and Prevention of Infant Mortality.*—Dr. C. N. Hewitt, of Red Wing, Minnesota, with authority to select associates.

*On Car Sanitation.*—Dr. Granville P. Conn, of Concord, New Hampshire; Mr. E. C. Jordan, C. E., of Portland, Maine; Dr. Domingo Orvananos, of Mexico; Professor S. H. Woodbridge, of Boston; and Dr. E. R. Lewis, of Kansas City.

*The International Committee on the Prevention and the Spread of Yellow Fever.*—Dr. Felix Formento, of New Orleans; Dr. George M. Sternberg, U. S. Army, Washington; Dr. Gregorio Mendizabal, of Orizaba, Mexico; Dr. Manuel Carmona y Valle, of Mexico; Dr. Jerome Cochran, of Mobile; Dr. Samuel R. Oliphant, of New Orleans; and Mr. Alfred V. Wood, of Brunswick, Georgia.

*On Steamship and Steamboat Sanitation.*—Dr. Frederick Montizambert, of Quebec; Dr. Samuel R. Oliphant, of New Orleans; Dr. H. B. Horlbeck, of Charleston, South Carolina; Dr. Albert L. Gihon, U. S. Navy, New York; and Dr. S. H. Durgin, of Boston.

*On the Transportation and the Disposal of the Dead.*—Dr. C. O. Probst, of Columbus, Ohio; Dr. Elzéar Pelletier, of Montreal; Dr. C. N. Hewitt; Dr. J. D. Griffith, of Kansas City; and Dr. P. H. Bryce, of Toronto, Ontario.

*On the Use of Alcoholic Drinks from a Sanitary Standpoint.*—Dr. Felix Formento, of New Orleans; Dr. C. O. Probst, of Columbus, Ohio; and Dr. E. P. Lachapelle, of Montreal.

*On the Centennial of Vaccination.*—Dr. T. Grange Simons, of Charleston, South Carolina; Dr. Joseph M. Toner, of Washington; Professor Charles A. Lindsley, of New Haven; Dr. Angel Contreras, of Puebla, Mexico; and Dr. N. S. Davis, of Chicago.

*On the Relation of Forestry to Public Health.*—Professor R. C. Kezie, of Lansing, Michigan; Dr. J. F. A. Adams, of Pittsfield, Massachusetts; Dr. Elzéar Pelletier, of Montreal; Dr. Salvador Garciadiego, of Guadalajara, Mexico; and Dr. Charles R. Walker, of Concord, New Hampshire.

*On the Transportation of Diseased Tissue by Mail.*—Dr. Henry Mitchell, of Trenton, New Jersey; Dr. E. P. Lachapelle, of Montreal; and Dr. Domingo Orvananos, of Mexico.

*On River Conservancy Boards of Supervision.*—Dr. H. P. Bryce, of Toronto, Ontario; Dr. C. O. Probst, of Columbus, Ohio; and Mr. Rudolph Hering, C. E., of New York.

*Chairman of the Local Committee of Arrangements.*—Dr. Ernest Wende, of Buffalo.

**Chemical Demorphinization.**—In the *Progrès médical* for August 1st, Dr. Albrecht Erlenmeyer calls attention to a new method of demorphinization which he calls the chemical method, and says that for nearly three years he has used it with the best results.

The clinical appreciation of certain symptoms of suppression, he says, should bring about a certain resemblance between these symptoms and those of dyspepsia which is due to hyperacidity. There may be found in

the two cases not only direct gastric symptoms, such as distention, intestinal pain, vomiting, diarrhoea, etc., but also indirect symptoms, such as heat in the spine, restlessness of the limbs and the body, and pain in the legs. This condition should lead to an investigation in order to ascertain if, at the time of suppression of the morphine, this same chemical alteration which is found in dyspepsia due to hyperacidity exists in the stomach, that is, if there is an excess of hydrochloric acid. In reality, says the author, these suppositions are true. At the time of demorphinization, when the patient receives no morphine or hardly any at all, and when the symptoms of suppression are the most violent, a considerable excess of hydrochloric acid has been found in the stomach.

Marmé, Stolnikow, and Rosenthal, says Dr. Erlenmeyer, have shown that a part of the morphine which is injected subcutaneously is transmitted to the stomach, and Alt ascertained that the portion which reached the stomach was about half of the dose injected, and that this elimination began a few minutes after the subcutaneous injection.

A consideration of this chemical process, continues the author, leads to the following reflections: In a person accustomed to take subcutaneous injections the morphine penetrates the walls of the stomach and produces morphinization of the secretory glands. This narcotic condition of the glands becomes almost permanent in persons addicted to morphine, and consequently the glands cease their functions; that is to say, they do not produce any hydrochloric acid, and the result is a non-acid condition of the stomach during the period of morphinization. The absence of the acid is not without influence on the gastric nerves; furthermore, these nerves are exposed to local narcotism, and it is easily seen that they will cease their functions under the influence of these two agents.

After the suppression of the morphine the condition is entirely different; the narcotic state of the secretory glands diminishes in proportion to the suppression of the morphine; they recover from the effects of the drug, resume their functions, and produce a veritable inundation of hydrochloric acid. This flow of acid influences the nerves and irritates them greatly, the result of which is a local and general trouble, namely, the so-called symptoms of suppression, such as vomiting, pain in the stomach, colic, diarrhoea, insomnia, acceleration of the pulse, heat and pain in the back, and restlessness of the limbs. It is useless to say that the nervous symptoms, aside from the gastric symptoms, are reflex results primarily produced by the irritation of the gastric nerves, then by the propagation of this irritation to the other tracts of the nervous system. If, says Dr. Erlenmeyer, these facts are admitted, it will not be difficult to find a rational treatment. Hitzig, he says, under the influence of these considerations, made the first attempt. At the time of suppression he emptied the stomach of a patient by means of a tube and in this way caused the disappearance of the hydrochloric acid; he then introduced into the stomach some alkaline water in order to neutralize what might have remained of the acid. The very interesting result of this procedure was that the patient was free, if not completely, at least partly, from the symptoms of abstinence. There were no local gastric symptoms or general or reflex symptoms; the heat and the pain in the back and the restlessness were also absent. The patient, who had undergone various methods of treatment for suppression of morphine, stated that the latter, that is the chemical method, was without

doubt the best, as it was more easily tolerated and gave rise to no grave symptoms.

The evacuation of the stomach by means of a tube is not an agreeable procedure, and often the patients are not able to tolerate it. In this case Dr. Erlenmeyer practises local neutralization by administering at least a pint a day of Fachingen water, which contains a large quantity of sodium bicarbonate. The effect of this medication, he says, is most unexpected; there is no vomiting or colic, and in place of the diarrhoea which, in other cases, caused so much uneasiness there is constipation. With regard to the reflex nervous symptoms, there are none at all, or they are so slight that the patients do not suffer from them. In three years Dr. Erlenmeyer has treated more than thirty patients in this way, and he states that recovery was incomparably easier to obtain than in those cases in which he employed other treatment, and he does not doubt that this method will become the treatment of the future. If it is successful, he says, it will be the true method of demorphinization.

**The Pig of the Bicêtre.**—A writer in the *Gazette hebdomadaire de médecine et de chirurgie* for August 9th says that, according to *l'Éclair*, the following is an authentic account of the mysterious abduction which had been referred to in another issue of that journal: In conformity with an ancient tradition, the internes of the Bicêtre fatten a pig every year in their garden for the Christmas festivals. The internes of a hospital in Paris, having cast envious eyes upon the animal, resolved to appropriate it for themselves. Accordingly, seven of them hired two carriages and drove out to the garden of the Bicêtre toward midnight. On their arriving at the garden, three of them were detailed to keep watch of the road while the others climbed the garden wall, which was rather low at this spot, and sprang upon the animal, that was sleeping peacefully. They tied its feet together, whereupon the animal began to grunt, and, in order to prevent any trouble, they chloroformed the pig, wrapped him in a sheet, and carefully carried him over the wall.

In the mean while, however, the two coachmen, who suspected that they were assisting in the commission of a crime, tried to get away, but the internes overtook them, told them who they were, and finally persuaded them that it was a joke, but the coachmen insisted on seeing the pig before they would believe it. On the return they were obliged to pass a toll-gate, which was altogether a different matter, and, after mature deliberation, they decided that the best way to deceive the officials was to pass without revealing anything, and to sing as loud as they could while passing the gates, in order to drown the grunting of the animal which had been heard from time to time. Everything took place as they had expected, and the young physicians passed the gate safely without giving rise to the least suspicion on the part of the officers. The rest of the journey was accomplished without any trouble until the rue Gay-Lussac was reached, when St. Anthony's companion awoke fully and gave vent to piercing cries. One of the physicians immediately sat upon its head to quiet it, which he did very effectually, for the animal relapsed into a state of syncope. The internes became alarmed at this and at once practised artificial respiration and rhythmical traction of the tongue of the poor animal, which was almost asphyxiated; but all their efforts were fruitless, for the pig died.

The joke did not end here; the internes decided to send to all their colleagues in the hospitals of Paris, in

the name of the internes of the Bicêtre, telegrams announcing the death of the animal and inviting them to attend a dinner—a funeral feast—which was to take place at the Bicêtre. The internes of the Bicêtre, who were furious at having received telegrams of condolence from all parts, resolved to respond by another joke. They erected in their garden a magnificent catafalque, and all those who were invited to dine were asked to march, one after the other, around the lighted catafalque, which contained an empty coffin! But no banquet followed. Thus terminated the joke of the pig of the Bicêtre.

**Mercurial Albuminuria.**—At a recent meeting of the Berlin Medical Society, a report of which appears in the *Annales de dermatologie et de syphiligraphie* for July, Dr. Fürbringer stated that Dr. Lewin had not observed a single case in which he could positively affirm that mercury had caused albuminuria, while the speaker himself had met with but eight per cent. of such cases in a period of ten years. With regard to the production of this albuminuria, he laid stress not only on the large doses of mercury, but on individual tendencies. It was to the latter especially that we should attribute the differences in the statistics. Lewin, he said, had often found albumin in the urine, but especially in that which contained a blennorrhagic secretion. When the kidneys were diseased, the mercury was excreted in large quantities by the intestine and gave rise to diarrhœa; consequently the renal function should be carefully watched, and great prudence should be exercised with patients who had previously had nephritis, scarlatina, etc. There were few organs in which relapses occurred so frequently as in the kidneys. Not only cold provoked relapses, but they also supervened during the elimination of mercury.

The diminution of the renal function, said Fürbringer, might also provoke albuminuria, and this diminution had been observed in cases of abundant sweating.

Dr. Grimm thought that the many investigations which had been made in regard to the employment of mercury in syphilis, relative to albuminuria, were not altogether free from objections, especially that which related to injections. Many accidents, he said, might be caused by subcutaneous injections, principally those that were intramuscular. The results of his experiments showed that the objections raised against this method were justified.

Dr. Blaschko said that, in regard to nephritis, it was less important to consider the nature of the preparation and its form of administration than the quantity of the mercury. The soluble preparations became insoluble at the moment of injection, because they formed mercury albuminates with the albumin of the tissues. This was particularly so in intramuscular injections, and important points to bear in mind were that too large doses must not be injected, and that as much precaution was necessary in employing the insoluble preparations as in using the soluble ones. Whatever the mode of administration, individual idiosyncrasies must be ascertained. When patients succumbed after a single application of mercurial ointment, after nephritis or after acute enteritis, we must bear in mind that similar results might ensue when mercury was given by subcutaneous or intramuscular injections, and caution must be exercised in regulating the dose, especially in the beginning. If there were no idiosyncrasies, the doses might be increased gradually without any unfavorable symptoms resulting except in rare cases.

Dr. Heller did not doubt the important rôle idiosyncrasy played in the origin of mercurial diseases, but it was curious, he said, in how few cases idiosyncrasies had been found in connection with the subcutaneous as compared with other methods of mercurial treatment. Consequently, he thought that the most essential condition for the development of mercurial albuminuria was the quantity of mercury employed.

**Are Copper Salts Dangerous?**—The *Nouveaux remèdes* for July 8th contains an article on this subject in which the writer refers to some remarkable experiments made by M. Galippe, of Paris, which, he says, have demonstrated conclusively the harmlessness of copper salts. It is only in acute conditions that, according to this author, poisoning by these substances can occur; and then it is not a question of true poisoning, but of a gastro-intestinal irritation analogous to that which is produced by a common caustic. Very exceptionally are serious symptoms of poisoning observed, as the organism has the greatest tendency to free itself from substances which are endowed with emetic properties.

M. Galippe, the writer continues, has been able to ingest for a number of consecutive days fifteen grains of a soluble copper salt without feeling any real inconvenience. In one instance he gave a dog an average daily dose of eight grains of copper acetate, and he noticed but very little vomiting or diarrhœa. However, Durand's, Orfila's, and Smith's experiments have shown the danger of copper salts; that they do not cause death by a veritable poisoning, but by troubles of the organism of slow evolution and by gastro-intestinal lesions to which they give rise.

M. Galippe wishes that the hygienists would insist on the harm that may be caused by the use of these salts, in order to prevent the public from eating vegetables to which a green color has been imparted by copper salts.

When the public has been warned against a danger that it ignores, says M. Duclaux, of Paris, the only thing to do is to put a stop to it by issuing a pamphlet containing words to this effect:

That, although copper salts are not sufficiently dangerous to lead to the suppression of their employment, yet manufacturers who use them must do so on their own responsibility, and all accidents which may be imputed to their products will be charged to them, even if it is proved that the contents of the box which caused the accident do not contain any more copper than those which have remained harmless.

Such terms, continues the writer, comport with the rights of every one, and it permits the judges before whom cases may come up to receive favorably the demand for damages from those who have suffered from the addition of foreign substances to their food.

**Slow Pulse with Pupillary Inequality following Scarlatina.**—M. Grancher contributes an article on this subject to the *Revue mensuelle des maladies de l'enfance* for August, in which he relates the history of a case which came under his observation. The patient, a child eleven years of age, made a rapid recovery; the daily examination of the urine revealed no albumin. A month after the beginning of the disease the patient left the hospital; the pupils were unequal and the pulse was slow; but he did not appear to suffer from these two symptoms.

M. Grancher, commenting on the case, says that the morbid syndrome presented by this patient is very distinct from that to which is given the name of perma-

nent slow pulse with attacks of syncope and epilepsy, or Stokes-Adams disease. While the true Stokes-Adams disease, he says, is rarely observed in persons under forty years of age, the slow pulse of nervous origin may be observed at all periods of life; its frequency at any given age is in proportion to that of the nervous lesions which may produce it, and it is not astonishing to see a permanent slow pulse in a child eleven years of age. Since this slow pulse is of nervous origin, the exception which it constitutes only confirms the rule.

The nervous lesions which produce permanent slow pulse, says M. Grancher, may be connected with any of the organs of innervation of the heart. The lesion may be situated in the heart itself, injuring the intracardiac ganglia. It may be connected with one or the other of the pneumogastric nerves which are compressed by a tumor. It may attack the bulb and the upper part of the medulla oblongata. It is only when the lesion affects this region that the coexistence of pupillary dilatation may be explained. Chauveau, says the author, has shown that at the upper part of the medulla a centre exists which is called the cilio-spinal, and extends from the sixth cervical vertebra to the second dorsal and governs the dilatation of the iris.

M. Grancher thinks that in his case there existed some trouble in this region of the spinal cord which attacked the cardio-spinal and the cilio-spinal centres. There had been no traumatism of the cervical vertebrae, and no trace of cervical Pott's disease, as pressure in this region did not give rise to any pain. As the trouble supervened during the course of an infectious disease, he is inclined to think that it was the result of infectious localization in the cilio-spinal and the cardio-spinal centres, analogous to those infectious localizations in the motor centres of the limbs which cause infantile paralysis. This hypothesis, he thinks, seems the most probable in the absence of anatomical verification.

**The Curative Treatment of Exanthematous Typhus by Artificial Serum.**—The *Revue internationale de médecine et de chirurgie* for August 10th contains an article by M. Sapelier, who gives a detailed account of twelve cases in which he employed this treatment, and the conclusions drawn therefrom: 1. Exanthematous typhus is generally infectious and eminently contagious, and it is often carried by infected persons to places where the disease has not existed. 2. Poor and half-starved persons are more liable to the disease than others. 3. Contagion occurs by direct contact with a sick person. 4. The average period of incubation is from ten to twenty-two days. 5. The microbian nature of the disease can not be doubted, but the germ remains unknown. The bacteriological examinations which were conducted in these cases did not reveal the presence of any micro-organism to which could be attributed any specific value. 6. In the last epidemic, dysphagia, unvarying meiosis, and myalgia were the three important symptoms which predominated. The mortality was terrible, the average percentage of deaths being eighty. Old men particularly were attacked with the disease; the women and children nearly always escaped; not a single case of true exanthematous typhus was observed among them. 7. Old men are more likely to succumb than adults, not to the typhus, but to the complications of the disease, as their organism may be weakened or diseased, or there may be functional troubles which are the result of various affections which have attacked them during the earlier periods of life.

In regard to the treatment, says M. Sapelier, cold baths should be regarded as dangerous in old persons and in those who have any heart trouble or who are affected with arterial sclerosis. The fall of temperature which the cold baths produce is not of sufficient duration to bring relief to the patients, but it is a good treatment in young persons. On the other hand, injections of artificial serum may be employed for patients of all ages and conditions at any stage of the disease. High fever is the best indication for the employment of the serum in typhus, and the liquid should be at a temperature of 86° F. at least. The advantage of this treatment over the cold baths, says the author, is that the lowering of the temperature lasts for twelve or fourteen hours.

In M. Sapelier's cases this treatment favored diuresis very greatly, and the albumin diminished rapidly and soon disappeared. Under the influence of the reduction of fever and the diuresis the toxins were easily and rapidly eliminated; the urotoxic coefficient was increased three and even fourfold. The eliminated toxins in proportion to their production diminished the organic infection and increased the resisting powers of the patients.

In M. Sapelier's experience this treatment, systematically applied in grave cases, lowered the mortality to fifty per cent. where formerly it had been eighty and eighty-five.

**The American Dermatological Association.**—The twentieth annual meeting will be held in Hot Springs, Va., on September 8th, 9th, and 10th, under the presidency of Dr. A. R. Robinson, of New York. The programme includes the following titles: Notes on Dermatitis Venenata, by Dr. J. G. White, of Philadelphia; Paget's Disease of the Nipple, by Dr. G. T. Jackson, of New York; Ulcerative Scleroderma, by Dr. P. A. Morrow, of New York; Two Cases of Arsenical Pigmentation, by Dr. W. A. Hardaway, of St. Louis; A Pathological and Clinical Classification of the Diseases of the Skin, by Dr. L. A. Duhring, of Philadelphia; Erythema Multiforme, with a Report of Two Cases, by Dr. W. T. Corlett, of Cleveland; A Peculiar Affection of the Mucous Membrane of the Lips and Mouth, by Dr. J. A. Fordyce, of New York; A Favuslike Eruption of the Oral Mucous Membrane caused by the *Aspergillus Niger*, by Dr. James M. Winfield, of Brooklyn; What Effect do Diet and Alcohol have upon the Causation and Course of the Eczematous Affections and Psoriasis? by Dr. J. C. White, of Boston; Cases of Mycosis Fungoides and Sarcomatosis, by Dr. J. T. Bowen, of Boston; Xanthoma Diabeticorum, by Dr. A. R. Robinson, of New York; Some Glycosuric Dermatoses, by Dr. C. W. Allen, of New York; The Relation of Dermatitis Herpetiformis to Certain Other Diseases, by Dr. L. A. Duhring, of Philadelphia; Bath Pruritus, by Dr. H. W. Stelwagon, of Philadelphia; An Eruption from the Local Use of Iodoform, by Dr. J. A. Fordyce, of New York; and Impetigo Contagiosa Universalis, by Dr. C. W. Allen, of New York. There will be an exhibition of drawings, water colors, colored photographs, photographs, and portraits of rare cases. Instruments and specimens will be presented, and microscopic preparations and photomicrographs demonstrated.

**Thyroids in the Treatment of Catalepsy.**—In the July number of the *American Journal of Insanity* Dr. Joseph G. Rogers, of the Northern Indiana Hospital for the Insane, gives an account of two cases which are of special interest because of the long duration of catalep-

tic conditions, and, still more so, because of the promptly beneficial effects of thyroid medication after the complete failure of other methods of treatment. The principal points in the more remarkable case, he says, are as follows:

In the fall of 1890, during or after an attack of malarial fever, the patient evinced mental aberration for about two weeks, with hallucinations and delusions of impending personal harm and legal involvement. Subsequently he was apparently well until the middle of January, 1892, when he was attacked by *la grippe*, speedily complicated by maniacal symptoms; he was noisy, restless, and sleepless; he had delusions of dread which were occasionally violent (he once fired a pistol at an imaginary enemy); he was very hilarious at times, laughing and singing without provocation, and then melancholy and dreamy.

He was admitted to the hospital two weeks later, on February 2, 1892, in a fair physical condition, and showed no salient symptoms of mental alienation in conversation or conduct, but his letters to relatives, shortly after, indicated delusions of conspiracy and revenge. He soon became accustomed to his surroundings, took part in the ward work and amusements, attended chapel and the dances, and was agreeable, cheerful, contented, well-behaved, and gentlemanly.

On June 9, 1892, he was sent home, apparently in a fair mental condition, but not discharged.

On October 14, 1892, he was returned to the hospital in a state of great mental depression, which had existed for some time previously. For some weeks following, at times, he would lie for hours in a trance, neither speaking, moving, nor giving attention to ordinary external impressions, and, if forcibly aroused, would at once become violent and strike those about him. Intermediately he was melancholy and silent, but would take some exercise and a sufficiency of food. The trance state, however, recurred more and more frequently, and on Christmas day, 1892, it became continuous, and nasal feeding was begun, because food placed in the mouth would remain unswallowed. (Meantime, however, he had been fairly well nourished.)

For three years continuously but little change in the case was manifested. He lay during all this period like a log, to all appearances wholly oblivious to external impressions or internal sensations, uttering no sound and making no sign indicative of mental action, unless it was an occasional secretion of tears which was often noticed. For many months the limbs could be readily placed in any position without positive resistance and would remain so placed for some time, however grotesque the attitude; later they became less flexible and assumed a fixed position, which could not be changed without the use of great force, which was avoided.

Sensibility to touch and pain seemed to be almost annulled; the faradaic current produced muscular contraction, but was not notably noticed by the patient. This condition continued without material change until November 1, 1895. During the first months of observation, tonics of various sorts, together with faradaic electricity, massage, and baths, were diligently used, but they were of no avail, and all treatment other than good feeding, frequent bathing, and careful attention to warmth of body was finally stopped. He suffered no intercurrent ailment; assimilation and excretion were sufficient and regular; there seemed to be no hopeful indication for any particular method of treatment, and none was attempted for many months, until the author

determined to test the efficacy of thyroids, and on November 1, 1895, the treatment was begun. On the 6th active movements of the fingers were noted, on the 24th the lips moved slightly, and on the 29th the patient extended his left arm almost straight. The average temperature increased a degree or more and became normal, while the pulse rose to 90. The treatment was suspended until December 16th, when it was resumed and continued until January 23d, at which time it was stopped on account of the rapid action of the heart. During this period of forty-one days of medication the temperature and respiration became normal and for a few days rose somewhat above it; the pulse remained at about 80 for two weeks, and gradually increased until it reached 140; it was soft, small, and regular. On the 17th of January the patient was placed in a sitting posture and was able to take a cup of cognog and drink it. On the 27th the temperature was 101° F. and the pulse 150; he laughed audibly and was quite restless. An attendant offered him a piece of paper and a pencil, and much to his surprise the patient took it and wrote that he would like to have his mouth washed out with a soft cloth, and that he would like a little cold water to drink. In the course of the evening he wrote several sentences. This condition lasted until February, when a complete relapse took place. On the 7th his condition was unchanged; on the 11th he was able to take soft food, and on the 23d he was able to speak. On the 29th he sat up during the day and ate well.

During the month of March no thyroids were given; the pulse went down gradually and it required two weeks to reach its normal state; respiration and temperature became slightly subnormal. The relapse toward inactivity, says Dr. Rogers, when the remedy was stopped was not so complete as before, but still very notable. For a time mastication was difficult. On March 9th the patient got up and walked with some assistance to another room. On the 12th massage was begun and on the 28th the use of the thyroids was again resumed. On April 7th there was a slight improvement, which gradually increased until May 27th. On that date the patient wrote a letter to his mother and was able to walk from one building to another. Since that time he has been mentally almost normal, and, although physically weak from long inactivity, he takes short drives and walks, and shows general evidence of having reached permanently a plane from which he may be reasonably expected to pass on to a condition of health.

The important deductions to be made from the histories of these cases, says Dr. Rogers, are the following:

1. That in conditions marked by inhibition of sensory, motor, and mental activity, without gross organic lesion, such as are met with in catatonica and in certain types of stuporous insanity and melancholia, we may expect benefit from thyroid medication, judiciously used.

2. That the effects of thyroids in full dose bear a striking resemblance to many of the symptoms of Graves's disease—namely, orbicular weakness, consecutive conjunctivitis, skin eruptions, and temporary bronzing, without icterus of the eyes, profuse local fetid sweats, subjective sense of heat and thirst, excessive metabolism, decided tachycardia, and the absence of any fixed relation between pulse rate, respiration, and temperature.

3. That the theory of Möbius, that Graves's disease is due to overactivity of the thyroid gland, is strongly supported.

**Diphtheria Antitoxine sometimes found in the Blood of Horses that have not been Injected with Toxine.**—In the July number of the *Journal of Experimental Medicine* Dr. B. Meade Bolton, of Philadelphia, remarks that every one who has undertaken the production of diphtheria antitoxine has encountered a marked difference in the behavior of the horses inoculated. With some horses, he says, it is a matter of very little difficulty to obtain antitoxine of high potency in a comparatively short time. With others it seems impossible to obtain strong antitoxine, and with others again there is such a violent reaction that it is impossible to continue the inoculations. Dr. Bolton thinks that the explanation of this may be found in the normal variation of the blood in the different animals. In order to test this, all the horses that were afterward used for the production of antitoxine for the laboratory of the board of health of Philadelphia were first tested as to the presence of antitoxine normally. In all, the blood serum of twelve healthy horses was tested previous to injection with diphtheria toxine. Out of this number three were found to possess antitoxine of such strength that three cubic centimetres of the serum were capable of neutralizing ten times the minimum fatal dose for guinea-pigs—i. e., one thirtieth of a normal antitoxine unit. In all three horses the strength of the antitoxine seemed to be the same. The guinea-pigs injected with three cubic centimetres all remained alive and well; those injected with a lesser amount all succumbed promptly to the accompanying dose of toxine. Injections of blood serum from horses not possessing normal antitoxine exerted no influence even in larger doses, up to five cubic centimetres. The difference, says Dr. Bolton, seems to be clearly one of quality and not of quantity, an essential difference in some constituent of the blood.

The behavior of the horses possessing antitoxine normally in their blood, the author remarks, presents certain points of interest on injections of toxine. These horses show much less reaction at the beginning than other horses, and it is possible to increase the doses to a certain point much more rapidly without causing alarming symptoms. After the dose has been increased till it reaches about a hundred cubic centimetres or more the reaction seems to be as marked as in horses that have had to be brought up to this dose more gradually. Experiments on two horses with antitoxine in their blood normally and two without antitoxine were begun together. One of the latter reacted so strongly that it was impossible to continue even with very small doses. The experiments on the three other horses have been continued. Up to the present time one of the horses with antitoxine normally present has received nearly three litres of toxine, the other over four litres, and the horse without the antitoxine normally present has received less than two litres, and yet they all show about the same amount of reaction at present from injections of a hundred cubic centimetres of toxine. At first, when the doses were small, there was practically no reaction in the horses in which the antitoxine was present normally, whereas in the other horse there was always decided reaction.

One of the horses with antitoxine normally present (the horse that has received about three litres of toxine) is beginning to furnish strong antitoxine, almost a thousand units to ten cubic centimetres. The other horse with antitoxine normally present (the horse that has received over four litres) furnishes very weak antitoxine, less than six hundred units to ten cubic centimetres.

The horse that had no antitoxine normally, that had received nearly two litres of toxine, furnishes quite strong antitoxine, almost a thousand units to ten cubic centimetres. It would seem from this, says Dr. Bolton, that the presence or absence of more or less antitoxine normally has no effect upon the ultimate production of artificial antitoxine by inoculation, but its presence enables the inoculations to be made with less risk to the animal.

It is difficult to explain the presence of antitoxine normally in the blood of horses. Wassermann, he says, found antitoxine in the blood of healthy persons, who stated that they had never had diphtheria, but he inclined to the belief that these persons at some period must have suffered from unrecognized diphtheria. Orłowski also found diphtheria antitoxine in the blood of children who had presumably never suffered from diphtheria, and he found it also in the blood of convalescents, as others had done. Orłowski, says Dr. Bolton, does not accept Wassermann's explanation, because he does not find that the age of the children has anything to do with the presence of normal antitoxine, and, moreover, he finds that the antitoxine present after convalescence disappears.

**A very Grave Case of Puerperal Streptococcic Infection in which Injections of Marmorek's Serum resulted in Recovery.**—In the July number of the *Revue de médecine* M. Ausset and M. Rouzé gave a detailed account of this case, in which, they said, the streptococcic infection could not have been more serious; it was a veritable septicæmia and it seemed as if the patient must succumb to the disease, but the very gravity of the infection had seemed to them an indication for the employment of Marmorek's serum.

The patient's blood seemed to have been poisoned by the microbe and by the toxines; and it appeared that curetting of the uterus would only lead to disastrous results. After four injections containing in all fifty cubic centimetres of serum, the disease was arrested. The authors add that they did not observe any symptoms in consequence of these injections, not even urticaria.

**Cancer of the Stomach treated with the Roentgen Rays.**—In the *Lyon médical* for August 9th M. Despeignes refers to a case, a full report of which appeared in the same journal for July 26th, in which the Roentgen rays were employed in the treatment of this disease. At that time, he says, a notable amelioration was observed, but unfortunately it did not continue. From the 12th of July, in fact, cachexia was re-established, and from the 22d to the 24th, on which date the patient died, there was an abundant diarrhoea with involuntary stools. Repeated injections of artificial serum and nutritive enemata were given, but they were of no avail. The Roentgen rays, however, continued to diminish the size of the tumor, and at the time of the patient's death it was considerably smaller.

From this experiment, says the author, three facts may be concluded: The treatment considerably ameliorated the general condition and prolonged the patient's life for fully two weeks, it absolutely suppressed the pain near the tumor, and, finally, it notably diminished the volume of the growth.

M. Despeignes thinks that the amelioration of the general condition may be mainly attributed to the injections of artificial serum, for when they were suspended at the patient's request, because they were painful, the general condition became worse. With regard to the

cessation of the pain, when the morphine injections ceased to have any further action, it did not seem possible to attribute the relief from pain to any other cause but the employment of the Röntgen rays, for from the beginning of the first sitting the pain ceased entirely. Before the employment of the rays the patient took daily doses of four ounces and a half of chloroform water, and very often two pills containing three quarters of a grain of extract of opium, and he frequently had one or two injections of morphine hydrochloride. After the employment of the rays the use of the opium pills was discontinued and only very small quantities of chloroform were given for two or three days. In regard to the diminution of the size of the tumor, says M. Despeignes, the action of the rays was still more distinct. As there was no autopsy, it was impossible to say what part of the tumor was influenced by the rays, but it is certain, he thinks, that the regression did not take place on the surface alone, but that the action of the rays was felt in the cancer; the epigastric region, which had been very much swollen on the 4th of July, was almost flat at the time of the patient's death. This diminution extended also to the right extremity, on the part which encircled the left lobe of the liver; when death occurred it was found on palpation and percussion that this lobe of the liver was completely free; and it seemed as if the cancer had completely disappeared, on that side at least, for, says the author, if the regression had taken place in the stomach only, it is probable that the contrary would have been the case. In the presence of these results, and although the termination was fatal, he asks, may there not be hope, if not of recovery, at least of a considerable prolongation of life by employing this treatment if the cancerous affection is not advanced, or is one in which the progress is not rapid?

M. Despeignes says he would not hesitate to use the rays in other cases of cancer of the stomach; furthermore, he strongly advises the employment of injections of artificial serum from the very beginning, and says that they should not be suspended under any pretext, for they contribute not a little to the amelioration of the general condition.

**The Marion Sims College of Medicine and the Medical Mirror, of St. Louis.**—We have received a proof slip of an editorial article in which Dr. I. N. Love, the editor of the *Medical Mirror*, announces that, after having served as a member of the faculty of the Marion Sims College of Medicine from the beginning, having been one of the charter members, and having seen the college develop until it is now recognized as one of the leading medical colleges of the West and South, he has tendered his resignation.

He says he has felt for two or three years past that his duty to himself and his own best interests lay in this direction, but a hesitancy in withdrawing from pleasant association with his colleagues until the success of the institution was secure has postponed the action. He says that in his letter of resignation he expressed his regrets and a warm personal regard for the faculty individually and collectively, and announced that his private practice, together with his conduct of the *Medical Mirror*, was such as to demand a more complete concentration than was possible with a continuance of college work. The resignation was accepted, with expressions of appreciation and good wishes. And now, being relieved to a degree of the inconvenience of having too many irons in the fire, Dr. Love feels that the *Medical Mirror* will be the gainer.

When he established the *Medical Mirror*, six years ago, he says, he announced that he had started upon a life work, and this determination has been strengthened as time has passed. He is ambitious not only to make the *Medical Mirror* one of the best medical magazines in the world, but to have it read by more doctors than any other. Plans that are under way now, he adds, will soon be consummated in the direction of the accomplishment of this end.

In saying good-bye to the Marion Sims College of Medicine and its faculty expresses in the most emphatic manner the hope that as the years come and go, the reputation of the college may go on increasing.

**The Treatment of Myopathy with the Thyroid Gland.**—In the *Revue internationale de médecine et de chirurgie* for August 10th, M. H. Meige states that M. Lépine has employed this treatment in two cases of myopathy and obtained successful results. To one patient, forty-four years old, who had suffered for eight years with the disease, two ounces daily, on an average, had been administered every week for a period of two months. The fresh gland was mixed with powdered marsh mallow. Amelioration had taken place in about two weeks after the beginning of the treatment. The patient felt stronger and had been able to walk alone, which he had not been able to do for some time.

In the second case M. Lépine ascertained that if the thyroid treatment did not improve the atrophy, it, on the other hand, considerably ameliorated the condition of the muscles, which had been affected for some time.

**Common Salt as a Cause of Bright's Disease.**—Dr. Giuseppe Levi, of Florence (*Sperimentale*, 1895, No. 3; *Deutsche Medizinisch-Zeitung*, August 6, 1896), has attempted to throw some light experimentally on a question raised by Bunge in his *Lehrbuch der physiologischen Chemie*, that of whether the work of excreting large amounts of sodium chloride did not irritate the kidneys, so that salt as well as alcohol might be classed as an excitant of nephritis. From experiments on dogs and rabbits, Levi comes to the conclusion that large amounts of common salt, from one to four grammes daily for each kilogramme of the animal's weight, given for a length of time, do give rise to renal lesions, but he does not speak of them as constituting nephritis, although mild inflammatory appearances were not wanting. Both the epithelia and the connective tissue were affected, alone or together. The lesions were similar to those attributed by other authors to various toxic substances.

**Citric Acid in the Treatment of Diphtheria.**—Dr. Bloch (*Ugeskrift for Læger; Deutsche Medizinisch-Zeitung*, August 10, 1896) reports that he has treated a hundred and fourteen cases of diphtheria with a ten-per-cent. solution of citric acid given by the mouth. Eleven deaths occurred, a mortality of 9.6 per cent. Fifty-six of the cases were mild, twenty-seven were of very doubtful prognosis, and thirty-one were decidedly grave. Four of the deaths were due to sepsis, one patient died after tracheotomy, and one died of paralysis of the heart during convalescence. Of the eleven who died, as many as five were not brought to the hospital until the disease had been running from four to seven days. According to the patient's age, Dr. Bloch gives from a teaspoonful to a tablespoonful of the solution every two hours. In the beginning and in severe cases, smaller doses are given, but more frequently, as often as every half hour day and night. In these cases warm applications are employed externally, and wine is given.

## Lectures and Addresses.

### LECTURES ON ANGINA PECTORIS AND ALLIED STATES.

By WILLIAM OSLER, M.D.,

PROFESSOR OF MEDICINE, JOHN HOPKINS UNIVERSITY, BALTIMORE.

#### LECTURE III.—ANGINA PECTORIS VERA.

##### PHENOMENA OF THE ATTACK.

(Concluded from page 284.)

**RESPIRATORY FEATURES.**—We have here to consider several important points—the symptoms in the attack, the relation of cardiac asthma to angina, and the interesting group of cases of chronic pleuro-pulmonic affections in which anginalike attacks of great intensity occur.

(a) In the attack, except slight acceleration in the movements, there may be no special changes. You will remember, in reading John Hunter's case, that, as he expressed it, he felt as though he had forgotten to breathe; and a patient may feel some sort of relief from the pain by voluntarily fixing the chest at the full inspiration, or by making a very forced expiration and holding the breath. In a lethal attack the respiration may become slowed and sighing, and a few gasps follow the abrupt cessation of the heart's action. One of the most remarkable features of the attack to which the attention was early called is the development of a bronchial asthma. Erasmus Darwin\* called the disease painful asthma—*asthma dolorificum*—without, so far as I can see from his account, any justification. On auscultation one hears over the chest numerous sibilant râles, and the breathing may become labored and expiration much prolonged. Huchard likens it to a condition of acute emphysema. In Case XXXII, which I gave you in full at the last lecture, the attacks of shortness of breath with piping râles formed a very distressing feature in the case. The expectoration was muco-purulent; Curschmann's spirals were never found. Throughout the illness, which persisted for several weeks, this condition continued, and was the cause of much annoyance. Though Heberden does not refer specially to the asthma, he speaks of two patients who had spat up blood and matter. Many patients have referred particularly to the "wheezing" which has accompanied the attacks. Goodhart,† who describes the condition as an acute bronchitis, thinks it of very grave prognosis. The same bronchial wheezing is present in some cases of cardiac asthma and doubtless gave the name to this symptom.

(b) Cardiac asthma may develop during an attack or alternate with the paroxysms of pain. In another lecture I shall speak more at length on the relations of this feature to angina, particularly to the angina pectoris *sine dolore*. Here I wish only to call your attention to

the distressing spells of dyspnoea, chiefly nocturnal, which may come on in the subject of angina, either independently of or following an attack. In the cases with advanced arterio-sclerosis the cardiac asthma may be the most pronounced and distressing feature, disturbing the patient nights, making him dread to fall asleep, owing to the horrible sensations which accompany the awakening in a paroxysm of dyspnoea. The subject may die in an attack of angina after a long series of asthmatic seizures. Case XXIII, Dr. —, aged forty-seven years, from Santa Fé, N. M., had advanced arterio-sclerosis. Fifteen months before his death he had an attack of angina; then for a year he had many attacks of cardiac dyspnoea, chiefly nocturnal, and once had transient hemiplegia with aphasia. He died after several paroxysms of terrible angina, recurring in the course of twelve hours.

Cardiac asthma is an everyday symptom in the course of chronic valve disease and cardio-sclerosis. In hospital practice it is as common as angina pectoris is rare. It may recur in paroxysms very like angina pectoris, in one of which the patient may die. Dreschfeld reports\* the case of a woman, aged forty-nine years, who, when younger, had been hysterical, and later very neurasthenic. Suddenly, one night she was seized with severe dyspnoea, without any cardiac pain. A week later she had a second attack, again without pain, and in a third attack, the following night, she died. There was a fibrous myocarditis at apex of left ventricle, and the left coronary artery was greatly narrowed by an atheromatous plate.

Cheyne-Stokes breathing is met with in the intervals between very severe attacks, as in Cases XXIII and XXXII, or is one of the manifestations of an advanced arteriosclerosis, as in Cases V, XI, and XIII.

(c) The term *respiratory form* of angina pectoris has been applied to cases of cardiac asthma, such as the one reported by Dreschfeld. I think the term more appropriate to that interesting group of cases in which the subjects of chronic pulmonary or pleural disease have agonizing paroxysms of pain about the heart, evidently of the nature of angina, and which may prove fatal.

Let me mention several illustrative cases:

**CASE IX.**—On February 12, 1891, I was consulted by a healthy, vigorous-looking man, aged thirty-three years, who complained of shortness of breath and attacks of agonizing pain in the chest.

In 1876 he had pleurisy on the right side, for which he was tapped repeatedly. The effusion becoming purulent, opened spontaneously, and the fistula took a long time to heal. He gradually got strong and well, and remained so for nearly ten years. In 1887 he began to have attacks of shortness of breath at night, with pain in the chest. At first there was no shortness of breath during the day except on active exertion. In the year 1888 the attacks recurred at intervals. In 1889 and

\* *Zoonomia*, third ed., 1801, p. 41.

† *Guy's Hospital Reports*, vol. xlv.

\* *Practitioner*, vol. xlv.

1890 he was very much incapacitated by them, as there was great pain and shortness of breath on attempting any extra exertion. The attacks came on with a feeling of great oppression in the chest, and a sense of overpowering constriction and uneasiness in the region of the heart. The pains never extended down the arms, but they passed up the neck to the head. Of late they have recurred at night with great regularity, so that he dreads to go to bed. He goes to sleep quietly, dreams a good deal, but always, prior to waking in pain, there is great excitement in the dreams, and he feels pressure on the eyeballs and forehead, which gradually increases until it awakes him. Then he arouses in terrible agony in both the chest and head, and the sweat pours from him. The paroxysm lasts from five to ten minutes, and he has often had to take chloroform. During these nocturnal attacks there is no shortness of breath, only the agonizing pain in the region of the heart and passing up the neck to the head.

On examination the patient showed an extreme grade of contraction of the right side, with lateral curvature of the spine, flattening in the mammary and axillary regions, with scarring in the seventh, eighth, and ninth spaces, where the empyema had perforated. On percussion there was flatness everywhere over this side; the left side was hyperresonant. The apex beat was not visible; the heart impulse could be felt with moderate force at the lower sternum. The heart sounds were perfectly clear and quite natural. The pulse was regular; the vessels were not sclerosed. There was no tracheal tugging, and the manubrium was clear on percussion. On rapid exertion the face became a little flushed, but no murmur developed over the heart. The urine was clear. The abdomen was distended, the right costal border was curiously everted from contraction of the chest, and the liver was drawn up very far. A short time after his visit to me the patient died suddenly in a paroxysm.

The following is a much less severe form of the same trouble:

A clergyman, aged forty-four years, came under my care April 20, 1892, with signs of local disease at the apex of the right lung. He was a vigorous, wiry looking man, who had had tuberculosis for several years; but the feature which incapacitated him for work was the occurrence during excitement, and especially when preaching, of attacks of indescribable distress about the heart, which on several occasions almost caused him to faint. It was not a sharp pain, and there was no radiation, but he described it as a feeling as though the heart would burst or break, and an entire impossibility to proceed with his sermon, or with his address. It was not accompanied with any shortness of breath, and though the signs of tuberculosis and of some compensatory emphysema were quite marked, yet it was this special symptom for which he sought relief, as by it he was incapacitated. The apex beat was not visible. The heart sounds were clear; there was no sign of hypertrophy, and the aortic second sound was not accentuated. The arteries were sclerotic, and the pulse tension was considerably increased.

The condition which this patient described, though probably not true angina, is of interest in connection with this subject. Public speakers and others who have to address audiences not infrequently complain of a peculiar sensation in the region of the heart, sometimes only an exaggeration of the ordinary embarrassment

which so many of us feel, but in other instances there may be, with an increased peripheral vasomotor contraction, quite evident in the pallor of the face, a summation of cardiac distress which becomes almost unbearable. I know of one professional friend who rarely can get up to speak in a meeting without considerable cardiac pain.

Cases of chronic pleurisy, tuberculous or otherwise, are very apt to have severe anginalike attacks. I have called your attention in the wards to Mary C., aged twenty-four years, with chronic bilateral pleurisy, who came under our care first in December, 1890, with an effusion on the right side. She has had lately severe attacks of pain in and about the heart which have come paroxysmally, but had never had the intensity of true angina. I saw this winter a woman, aged thirty-six years, who had had a pleurisy on the right side of thirteen years' duration, with chronic disease of both apices, and considerable enlargement of the heart. She had had shortness of breath, and occasional pain about the heart on exertion. She died in an attack of acute dilatation of the heart, associated with a great deal of substernal pain, much pallor, and sweating.

GASTRO-INTESTINAL SYMPTOMS.—Nausea not infrequently accompanies the attack, and the patient may vomit. Heberden notes that "persons who have persevered in walking till the pain has returned four or five times have then sometimes vomited." As an attack ends the patient may belch quantities of gas, or pass flatus from the bowel, both with apparently great relief.

Flatulency was regarded by Butter as "the most obvious and the most regular exciting cause." Parry, too, laid great stress on the influence of eructations in mitigating the pains produced by "mal-organization of the large vessels," and quotes Morgagni to the effect that the vulgar, and even the physicians, thought the disease originated in the flatulency. There is another important relation of the gastro-intestinal features of angina pectoris. When the pain is situated in the scrobiculus cordis, and associated with eructations and dyspepsia, the diagnosis of gastralgia may be made. There are several very interesting papers on this question in the literature. Leared\* described a series of cases of "disguised disease of the heart" in which the "heart affection was so strangely masked by that of the stomach that nothing in the statements of the patients had any bearing on the primary disease." In several of his cases sudden death followed. Barié† has written an elaborate paper on the cardio-pulmonary features of gastro-hepatic disorders. The attacks of pain in some of his cases simulated closely angina. Huchard has a special section on what he called the *pseudo-gastralgic* form of angina.

In only two cases in my series were the gastric symptoms of such intensity that the affection was at first thought to be in the stomach.

In Case XIX the pains were at first altogether in the

\* *Medical Times and Gazette*, 1867, i.

† *Revue de médecine*, 1882.

upper part of the abdomen, and as they were of sufficient intensity to cause vomiting she was thought to have gastralgia. It was not until dyspnoea came on, and the pains became centred about the heart and extended to the neck and arm, that the diagnosis of angina was made.

In the following case the patient, a most intelligent man, insisted that the entire trouble was in his stomach.

CASE XXVII.—Mr. W., a merchant from North Carolina, was referred to me by Dr. Whitehead, October 26, 1893, complaining of severe attacks of pain in the abdomen and lower part of the chest. He was sixty-seven years of age, and of excellent family history. All his life he had had occasional attacks of indigestion.

On the 17th of June, 1893, after helping a servant to carry a heavy trunk upstairs, he felt a sensation at the pit of the stomach as if he had wrenched himself badly. A few days later, while walking up a hill, the sensation of pain in the stomach returned, and a week later, while walking fast to catch a train, he had very severe pain and shortness of breath. The taking of food apparently made no difference to the pain, but he had a good deal of belching of wind, and he insisted upon regarding the condition as altogether due to his stomach. Dr. Whitehead, in describing the case, stated that the pain began in the epigastrium and passed directly to the backbone; if very severe, it spread over the thorax; "asthma comes on; there is tingling sensation in the left hand, and violent pains are felt in the arms. The agony is simply terrific." He never had any nausea or vomiting in the attacks. The patient was a very well preserved man; the radials were firm, tension was increased, and the radial pulse was anastomotic. There was no excessive cardiac impulse, the area of dullness was not increased, but the subcutaneous fat was very excessive. With the exception of a soft apex systolic murmur, auscultation gave no indications. The second sound over the aortic region was of medium intensity. The examination of the abdominal organs was negative. There was no dilatation of the stomach and the gastric juice was normal. The note which I made with reference to the nature of the case at the time was as follows: "Though the possibility has been entertained that Mr. W. has gastralgia, due either to ulcer or cancer, it seems to me much more likely that he has angina pectoris." He was ordered iodide of potassium; and throughout the winter of 1893-'94 he did very well, and he could walk a distance of two or three blocks without suffering pain.

On July 2, 1894, after eating a much heartier dinner than usual, he went out to pay a visit, and on leaving the door of the house fell forward on the verandah and died in a few moments.

Another by no means uncommon and often very distressing symptom is persistent hiccough.

A symptom described by some writers has been the constant desire to urinate—urina spastica—and there may be a very large amount of urine passed. Griffiths and Massey\* profess to have separated a special leucomaine from the urine passed during the attack.

NERVOUS AND PSYCHICAL SYMPTOMS.—The mental anguish has been described. A sense of faintness almost invariably accompanies severe attacks, and actual loss of consciousness, syncope, may follow, upon which feature

I have already dwelt. There are interesting psychical manifestations in angina pectoris upon which you will not find much in the literature. They are features of the myocarditis, rather than of the angina, and develop with the progressive weakness of the heart. In Case V the patient had delusions of a most painful nature for nearly six weeks, during which time he had an exceedingly feeble heart, with gallop rhythm. He recovered and lived for three years. In Case VIII the patient thought that he was in a strange house and begged constantly to be taken to his home. You remember that in Case XXXII there were occasional delusions.

Trousseau believed that there was a close relationship between angina pectoris and epilepsy: "In some cases, and perhaps in a pretty good number of instances according to my experience, angina pectoris is an expression of this cruel and fearful complaint, and is a variety of the vertiginous form of the disease—in other words, it is an epileptiform neuralgia. Its invasion is as sudden, its progress as rapid, and its disappearance as sudden, and, as I have already told you, it is not of very uncommon occurrence to find persons who have in former years suffered from angina pectoris become subject afterward to epileptic fits, just as in other instances angina pectoris has been preceded by well-marked epileptiform seizures."\* Quite recently Richardson† has urged that angina pectoris is a special disease, of a paroxysmal nature, as distinct as epilepsy and partaking in many ways of its features—a sort of epileptic counterpart in the sympathetic system. The two diseases may co-exist. We have to distinguish between the attacks of nervous palpitation with cardialgia in epileptics, not infrequent symptoms, and attacks of true angina. The only instance of combination of the two disorders which I have met is the following:

CASE III.—An engraver, aged forty-eight years, was admitted under my care to the University Hospital, Philadelphia. He had served in the army during the war of secession, and entered the navy as a marine in 1871. After a blow on the side of the head, in the latter part of 1873, he was insane for several months and required constant watching. He recovered, but has had ever since, at intervals, epileptic attacks, and he has frequently been picked up unconscious on the street. For the past four years he has had also violent pains in the chest with choking sensation, difficulty in swallowing, and shooting pains down the left arm. He does not lose consciousness during these attacks, but they are evidently of terrible severity, and he feels in each one as if he were about to die. He has a well-marked aura preceding the epileptic fit, which starts in the lower part of the chest, but he is not aware of any close association between the epilepsy and the attacks of angina. The patient was in a very bad condition on admission, almost pulseless at the wrist, but after the administration of whisky and digitalis he revived, and in a few days seemed quite himself again. He had hypertrophy of the heart, with aortic insufficiency.

\* *Clinical Medicine*. New Sydenham Society edition, vol. i. p. 662.

† *Asclepiad*, vol. xi.

\* *Comptes rendus, Acad. des sciences*, 1895, 1128.

There was in the wards last June (1895) a colored man, aged thirty-four years, who had remarkable attacks of pain about the heart with unconsciousness. He was a healthy-looking fellow, the pulse was not slow, the tension was increased, but the radials felt a little hard. The heart was not enlarged; the aortic second sound was a little accentuated. The urine was normal. He had probably had syphilis. Eight years ago he began to have pains about the heart, and from July to September the attacks were so severe that he was unable to work. In December they returned, and ever since, at intervals, he has been subject to them. Any extra exertion, such as walking fast up hill, or mental excitement will cause severe pain, exactly under the left nipple, often of great severity. In March of this year, while working in a stable, he felt a sudden agonizing pain in the heart, became giddy, and fell to the floor unconscious. He did not bite his tongue, and, so far as we know, he did not "work" the muscles or foam at the mouth. On June 17th he had a second attack, with very much more pain about the heart, which lasted for five or ten minutes before he became unconscious. On the 24th he was walking on the street, felt a severe pain and great oppression about the heart, and then fell unconscious and was brought to the hospital by the police patrol. The loss of consciousness lasted several hours. He had no attacks while in the ward, and it seemed impossible to determine precisely the nature of the case—whether the so-called cardiac epilepsy, or an anomalous type of angina pectoris. Newton\* has reported an interesting case in which very probably both the epilepsy and the angina were associated with syphilis.

### THE PRODUCTION OF IMMUNITY TO HOG CHOLERA

BY MEANS OF

#### THE BLOOD SERUM OF IMMUNE ANIMALS.

ANTITOXIC SERUMS FOR HOG CHOLERA AND  
SWINE PLAGUE.

By E. A. DE SCHWEINITZ, Ph. D., M. D.

In the *Medical News* of September 24, 1892, I published the results of some experiments made upon guinea-pigs with the blood-serum of immune guinea-pigs, which proved that an injection of such serum would protect other guinea-pigs from hog cholera. Subsequently Dr. Theobald Smith and Dr. Moore conducted some similar experiments with rabbits, and, while these were not made entirely immune by the quantity of serum used, they showed great resistance to the disease. They did not carry this work upon rabbits further, though the indica-

tions were that immunity would have been produced had the doses of serum been larger.

As an accidental result of an experiment to show if the products of the *Bacillus coli communis* would serve to immunize against hog cholera, our experiments have been continued to see if the blood of the immunized hog would also induce immunity in other animals, as guinea-pigs, against hog cholera. The results proved that such immunity could be secured.

June 13, 1895, guinea-pigs were given blood serum from an immune hog (No. 151, killed June 11, 1895).

No. 425, weight 11 oz., received	3.0 c. c.
" 426, " 9 " "	4.5 " "
" 423, " 11 " "	1.5 " "
" 422, " 9 " "	0.5 " "
" 424, " 8 " "	2.0 " "

On June 15th pig No. 424 was found dead from blood-poisoning.

On June 20th pig No. 425 was found dead from blood-poisoning and pleurisy. On June 19th, 1895, two pigs were inoculated with the nucleinlike substance obtained from the same serum that was used to inject the other guinea-pigs. Each pig received 0.06 gramme of the supposed active principle of the blood.

No. 416, weight	3½ oz.
" 417, " "	14 " "

June 28, 1895, two checks, Nos. 442 and 443, and treated pigs Nos. 416, 417, 422, 423, and 426 were inoculated with a one tenth cubic centimetre hog-cholera culture on peptonized beef broth one day old.

July 5, No. 416 was found dead,	
" 8, " 417 " " "	
" 5, " 442 " " "	
" 3, " 443 " " "	

all upon autopsy showing characteristic hog-cholera lesions.

The other inoculated animals appeared to recover and were well. On December 21st, six months after exposure to the disease, guinea-pig No. 426 was found dead. Autopsy, however, showed that the animal had died from pneumonia.

Again, December 26, 1895, serum from hog No. 150 killed, and serum collected December 24th was used to inject two pigs:

No. 73, weight 16 oz., received	3.0 c. c. serum.
" 51, " 17 " "	4.5 " "

On January 25th these pigs, checks, and Nos. 379, 377, and 376, the latter inoculated last in May, received one tenth cubic centimetre hog-cholera culture.

On January 31st Nos. 73 and 51 and checks were found dead from hog cholera, while the others, although apparently a little ill for a few days, had recovered.

These experiments show that an immunizing substance is produced in the blood of the protected hog; that, while the animal itself may remain immune to disease, as is shown by the guinea-pigs, its blood will have lost the power of conferring immunity to other animals. This confirms the conclusion in other diseases in the

\* *Medical Record*, 1893, 1.

use of blood serum, that the immunizing principle of the blood serum can be kept constant only by having the animals reinoculated from time to time. Apparently the antitoxic substance can be the product of cell activity only. So long as the animal is kept inoculated with the toxine or the germ, not only does the immunity of that particular animal continue, but the antitoxic substance is found in the blood. After some intermission the antitoxic substance is contained in the blood, only in small amount, but the immunity of the individual still continues. In the use of antitoxic serum, therefore, its efficacy lies in the fact probably that, counteracting the poison first produced by the germs, it gives the cells the opportunity to recover their temporarily weakened activity and supply more antitoxic substances. The experiments prove that the serum of immune hogs can produce immunity in guinea-pigs, and that a distinctive antitoxic substance must be formed.

This conclusion as to a distinctive antitoxic substance was confirmed in the following experiments, in which antitoxic serums were used in an attempt to cure both hog cholera and swine plague in guinea-pigs.

The antitoxic serum for the hog cholera was obtained from a cow which had been treated by Dr. Schroeder, for some time, at the experiment station of the bureau.

#### March 9th:

Guinea-pigs.	
No. 223, weight	12 oz.
" 222, "	17 "
" 221, "	11 "
" 220, "	12 "
" 219, "	17 "

Each received a cubic centimetre and a half of serum from cow No. 24.

16th: No. 221 died from pneumonia.

#### 18th:

No. 223, weight	14 oz.
" 222, "	19 "
" 220, "	11 "
" 219, "	18 "

Each received three cubic centimetres of serum.

#### 23d:

No. 219, weight	17 oz.
" 222, "	17 "
" 246, "	9½ "
" 242, "	10½ "
" 243, "	10½ "

Nos. 219 and 222 each received a cubic centimetre and a half of serum and the remainder three cubic centimetres of serum each.

#### 28th:

No. 242, weight 12 oz., received	3·0 c. c.
" 243, " 12 " "	3·0 " "
" 246, " 11 " "	3·0 " "
" 223, " 13 " "	4·0 " "
" 219, " 18 " "	4·5 " "
" 222, " 18 " "	6·0 " "

of the same serum.

On March 20th No. 220 had been found dead from pneumonia.

On April 9th the following pigs were inoculated with a one tenth cubic centimetre of hog-cholera culture each.

No. 230, weight	23 oz.
" 222, "	10 "
" 223, "	12 "
" 242, "	13 "
" 243, "	13 "
" 246, "	12 "
" 260, "	12 " check.
" 261, "	12 "
" 262, "	15 "
" 263, "	20 "
" 264, "	14 "
" 241, "	15 " check.

#### April 11th:

No. 261 received	3·0 c. c. serum.
" 262 "	3·0 " "
" 263 "	5·0 " "
" 264 "	4·5 " "

#### 14th:

No. 261, weight 11 oz., received	3·0 c. c. serum.
" 262, " 13 " "	3·0 " "
" 263, " 17 " "	4·5 " "

17th: No. 260 check was found dead from hog cholera.

19th: No. 222 was found dead from hog cholera.

20th: No. 264 was found dead from hog cholera, autopsy showing characteristic post-mortem appearance except a slight complication with pneumonia.

25th: No. 241 check was found dead from hog cholera. Nos. 219 and 223 were also found dead, showing evidence of pneumonia in addition to hog cholera, and No. 261, found dead on April 25, 1896, showed upper lobe of right lung consolidated from pneumonia, in addition to coagulation necrosis of the liver. There had been quite an outbreak of pneumonia among the guinea-pigs, which accounted for these lesions. Of the entire number of pigs, therefore, of those that had been previously inoculated with serum, three animals (Nos. 243, 242, 246) that had been vaccinated with six cubic centimetres each of serum and two (Nos. 262 and 263) that had received six and eight cubic centimetres of serum each after inoculation, recovered from the disease. Had the pigs not been exposed to infection with pneumonia it is likely all would have recovered.

This experiment, repeated later, showed that while the blood contained an antitoxic principle, the amount was not sufficient to cure the disease by the injection of sufficiently small doses, and we are now endeavoring to increase the amount of antitoxine in the blood of the cow.

As my experiment in 1891 with the products of the swine-plague germ had shown that these could be used for the production of immunity, and subsequently Dr. Smith and Dr. Moore had satisfactorily produced immunity by the inoculation with serum from immune

animals, it was very reasonable to suppose, when the nature of this disease is remembered, that an antitoxic serum for swine plague could be easily obtained. A cow was again used for the source of the serum after she had been repeatedly inoculated. The preliminary tests were made upon rabbits. A twentieth cubic centimetre of a peptonized beef-broth culture of swine-plague germ was sufficient to kill a rabbit in fifteen to eighteen hours. Several sets of experiments showed that while the checks died within the required time other rabbits, inoculated at the same time and with the same quantity of culture, could be kept alive from six to ten days longer than the checks by the injection of nine cubic centimetres of serum per pound weight. As an antitoxic substance was present in the serum, therefore, I tried its effects upon guinea-pigs. One tenth cubic centimetre of the culture used was sufficient to kill a guinea-pig in forty-eight hours. The experiment was as follows:

July 10th:

Guinea-pigs.

No. 348,	weight 12 oz.,	check, received.	$\frac{1}{10}$ c. c. swine plague culture.	
" 349,	" 8 "	" .. 3 "	" "	serum.
" 350,	" 11 "	" .. 5 "	" "	"
" 351,	" 9 "	" .. 6 "	" "	"
" 352,	" 8 "	" .. 6 "	" "	"
" 353,	" 8 "	" .. 12 "	" "	"

On July 20th the check was found dead. On July 29th the pig that had received the serum alone was found dead, autopsy showing peritonitis, pleurisy, and pericarditis, which were apparently produced by the large dose of serum. The pigs receiving the antitoxic serum recovered, according to the doses given, six cubic centimetres per pound weight being required to check the disease.

I next tried, with the assistance of Dr. Dorset, to isolate the antitoxic principle from the serum, according to a method given by Bieger and Boer for the isolation of diphtheria antitoxine (*Zeit. für Hyg.*, Bd. xxi, Pt. 2) by the use of zinc sulphate, repeated solution in NaOH, and precipitation with CO<sub>2</sub>. In this way from ninety cubic centimetres of serum we obtained 1500 grammes of a white, practically ash-free powder.

The antitoxic properties of this substance are now being tested.

In one set of experiments guinea-pigs inoculated with hog cholera were given swine-plague serum, and other pigs inoculated with swine plague were given hog-cholera serum. These serums were without effect, except in case of their corresponding disease, showing again their independent character—the swine-plague serum from swine plague only, and the hog-cholera serum from hog cholera only. These preliminary experiments serve to show us that specific antitoxic serums for hog cholera and swine plague may be obtained. A more detailed account of these and other results will be published as a department bulletin.

DEPARTMENT OF AGRICULTURE, BIOCHEMICAL LABORATORY,  
BUREAU OF ANIMAL INDUSTRY, WASHINGTON, D. C., July 30, 1896.

## RECENT ADVANCES IN THE SURGICAL TREATMENT OF MALIGNANT DISEASE OF THE LARYNX.\*

By D. BRYSON DELAVAN, M.D.

WHILE operations for the relief of the less malignant forms of laryngeal growths have often proved successful, the radical treatment of epithelioma of the larynx heretofore has practically resulted in failure. True, in a few brilliant exceptions, life has been lengthened and the comfort of the patient materially increased by the removal of the whole or a part of the diseased organ. A careful survey of the subject, however, will compel the admission that, in general, the lives of patients suffering from epithelioma of the larynx have been shortened rather than lengthened by the efforts of the surgeon. This statement is based upon the fact that the average duration of life in such cases, without attempted removal of the larynx, is about a year and a half. The number of cases in which the subjects of laryngectomy have survived for double that length of time is very small. In view of the total failure of other methods of relief, we are obliged at present to regard surgery as the only possible resource, and, in spite of the above-mentioned facts, rely upon its aid until something better has been proposed. It is of the highest importance, therefore, that the possibilities attending operative measures be appreciated and improved.

Fortunately, indications are not wanting that there exists for this class of operations a not altogether unpromising future. Here and there a case is reported which among many failures proves the exception to the rule in that the result of operations has been actually to prolong the patient's life. Within the past year three papers have been published in which the proportion of successful operations has been unusually large, and while the actual number of patients operated upon has been too small to establish any positive conclusions, and the dates of most of the operations have been too recent to admit of a complete study of the cases themselves, there can be no question that the work recorded in them is, on the whole, worthy of careful consideration. The varieties of operation which have lately challenged attention by reason of the improvements which they have offered may be divided into three groups: (1) Thyrectomy, with or without partial laryngectomy, (2) complete laryngectomy by the method adopted in Solis-Cohen's case, and (3) complete laryngectomy in cases of extensive laryngeal disease with glandular involvement. Examples of all three are beginning to multiply to such an extent that it will not be long before we shall have a collection of details sufficient to afford a fairly positive knowledge of their real value, together with a fund

\* Read before the American Laryngological Association at its eighteenth annual congress.

of technical knowledge relating to the subject which can not fail to be of material aid for future guidance.

A short consideration of these methods may not be without interest. The first variety, while advocated by many surgeons here and abroad, has been studied and practised in this country chiefly by Professor Clinton Wagner, of New York, and by Mr. H. T. Butlin and Dr. Semon, of London. It consists in performing thyrotomy and removing as much of the diseased tissues as may be necessary. Mr. Butlin, in the main agreeing with many of the best surgeons of the day, has advanced the following propositions:

1. Every malignant growth of the larynx of intrinsic origin which can be dealt with should be treated by an operation in the absence of a decided indication to the contrary, and the operation should be performed with the least possible delay.

2. Every tumor of the larynx suspected to be malignant, of intrinsic origin, of limited extent, and apparently within reach of free removal, justifies an exploratory thyrotomy in a suitable patient, in the absence of infiltration of the surrounding structures and of affection of the lymphatic glands.

The method of operating pursued by Butlin and Semon has been described in their published writings. It applies distinctly to cases in which the disease is absolutely confined to the interior of the larynx. Preliminary tracheotomy is done, with the insertion of the tampon cannula and its careful adjustment. The anterior part of the thyroid cartilage is laid bare with scalpel and raspatory, it is opened exactly in the median line, and the two sides of the larynx are held apart, preferably with two strands of strong silk inserted through the anterior parts of the lateral wings of the thyroid. After the latter has been split open, undue violence in holding the halves apart must be strictly avoided. At this stage it will generally be necessary to protect the parts from mucus and saliva by packing the lower part of the pharynx with a large aseptic sponge secured by a string and passed through the laryngeal wound upward. There are two recommendations upon which Semon lays special stress: First, the surgeon should be provided with a forehead reflector and a good light, and, as has already been suggested by the writer for deep operations in the pharynx, he should, if possible, have at hand a small two- to four-candle-power electric lamp, to be used for the purpose of securing the best possible illumination of the interior of the larynx for the detection of every possible bit of diseased tissue. Secondly, before he begins the removal of the growth the whole side of the larynx to be operated upon should have applied to it a five-per-cent. solution of cocaine, for the purpose of contracting the capillaries on that side and preventing parenchymatous bleeding, which otherwise is sure to interfere with and greatly prolong the removal of the growth proper, while at the same time it may allow suspicious portions to remain behind.

The importance of the two above-mentioned measures is strongly insisted upon. The field of operation having been thus prepared, the diseased soft tissues are thoroughly removed to at least half an inch from the periphery of the growth, and, if necessary, the underlying cartilage is scraped or even removed, the base being firmly scraped with a sharp spoon. The use of the galvanocautery will seldom be required. Every source of bleeding having been stopped, the whole interior of the wound is dusted with pulverized iodoform, or with iodoform and boric acid in equal parts, and the tampon cannula is immediately removed. The whole of the wound is then covered with cyanide or iodoform gauze.

In cases where the more extensive resection of the thyroid or even extirpation of one half of the larynx is contemplated, the parts of cartilage to be removed should be freed from their perichondrium and from the surrounding soft parts, by means of an elevator. In other respects the operation is the same, only more extensive than mere thyrotomy with removal of soft parts. It is generally not necessary to prophylactically ligate the laryngeal arteries. Where the epiglottis or the aryteno-epiglottidean fold are diseased, the best means of access to them is subhyoidan pharyngotomy.

For after-treatment, both Wagner and Butlin immediately remove the tampon cannula, and from that time use no tracheal cannula whatever, and, the wound having been dressed as above described, the patient is not propped up in bed, but is placed horizontally on the side corresponding to the half of the larynx operated upon, with one small pillow under the head. Instead of plugging the wound with gauze, as formerly, Mr. Butlin dusts it at least twice daily for the first few days with the antiseptic powder by means of a powder insufflator. The application can be made to the best advantage when the patient is swallowing, as during the act of deglutition the wound in the neck is separated sufficiently to admit the end of the powder blower, so that the powder may be thrown from it directly against the raw surfaces, which should be thoroughly covered by it. The external covering of cyanide or iodoform gauze should be removed as often as wet by secretion. Although nutrient enemata may be required for the first few days, the experiment may be tried on the day of the operation, or soon thereafter, of allowing the patient to attempt to drink a little water while leaning with the upper part of the body well over the edge of the bed. In case of any impediment to the closure of the larynx during this act, the water will run directly out of the wound and no harm result; should the experiment succeed, milk may at once be taken in the same way, and the necessity for rectal feeding avoided. The external wound gradually closes by granulations, which may have to be stimulated by applications of nitrate of silver.

Clinton Wagner \* reports fifteen thyrotomies per-

\* *Medical Record*, January 4, 1896.

formed upon patients varying in age from sixty-four years to eighteen months. Five of the patients are now living, at periods of one year, one year plus, twelve years, twelve years, and seventeen years respectively. Of those not now living, one survived four years, two one year, one three months, and one ten weeks. In none of the latter cases was death due to the operation of thyrectomy. Classified as to diagnosis, four of them were cases of epithelioma; these patients lived, respectively, four years, one year, three months, and ten weeks; one case was one of echondroma, and the patient was alive when last heard from; three were papillomata and two cicatricial stenosis.

Of the cases of epithelioma reported by Dr. Semon, five patients died from the operation within periods varying from one to six days. One showed probable recurrence within four months. Of the remaining four, one operated upon by Hahn—by complete laryngectomy—lived six years and a half without recurrence, and died of heart disease. There are living and well one operated upon by Dr. Butlin at five years and a half, one at three years, and one at two years, the latter operated upon by Semon.

Comparing recent results with the general statistics lately reported by Powers—namely, eleven per cent. of recoveries in complete laryngectomy and thirteen per cent. of recoveries in partial laryngectomy—it will be seen that as to thyrectomy such a distinct advance has been made that its value, as at present performed, can not be questioned.

Turning now to the method of operation classified as number two, let me call attention to the patient named Daniel Hickey, who was operated upon five years ago by Dr. Solis-Cohen, of Philadelphia. In this operation, as in several similar to it by Poppert, Schmidt, Swain, and Carmalt, and possibly at this date others, the larynx was completely removed and the severed end of the trachea brought to the external edges of the cervical incision and there retained, communication between the lungs and the pharynx being thus totally and absolutely cut off. The great advantages of this plan over the usual methods have already been demonstrated to you.

1. The danger to life from inspiration-pneumonia is greatly lessened, owing to the shutting off of the mouth from the trachea.

2. Swallowing is accomplished with great ease and as freely as under ordinary circumstances.

3. In at least three cases thus operated upon the power of phonation has been acquired with a voice fully as satisfactory as that produced by any artificial appliance, and without either the inconvenience and discomfort of an artificial larynx or the danger to the adjacent parts from the irritation of its presence. The mechanism by which phonation is accomplished in these extraordinary cases has not been explained. Cohen's patient is able to make his voice distinctly heard from one

end to the other of the great hall of the New York Academy of Medicine.

4. The comfort of the patient is greatly increased, and the disfigurement of the other operation and of the wearing of the artificial larynx largely done away with. It is entirely probable that, under certain conditions, this method will prove to be the most satisfactory for complete laryngectomy of any yet proposed, and it is to be hoped that it may be given a sufficient trial to prove whether or not the cases already reported have been but the result of a happy accident rather than the first illustrations of a definite rule.

As to the third variety of operation, it has often been insisted that, in order to insure success, malignant disease of the larynx must be treated as early in its history as possible, and at least before involvement of the neighboring glands has taken place. Unfortunately, in the history of the past, early operation has not always saved life, and, on the other hand, several eminently successful cases have been in patients who suffered from a tolerably extensive condition of disease. The management of cases of extensive laryngeal disease, therefore, becomes a matter not only of great importance, but of lively interest, especially when it is remembered that perhaps a majority of patients are not seen by the specialist or surgeon until the disease has made considerable progress and the time most favorable for operation has passed.

Several years ago operations were attempted upon such patients with only here and there an exception to the inevitably and immediately bad result. Subsequently they were pretty generally left to their fate. Of late, under the influence of improved methods and increasing knowledge, a hope, small indeed, but worthy of all encouragement, has been aroused by the excellent work of several men. Prominent among these may be mentioned the name of Mr. Watson Cheyne, of King's College Hospital, London, whose efforts in this direction are now attracting much attention, and who, in his admirable Lettsomian Lectures\* upon The Objects and Limits of Operations for Cancer, delivered before the Medical Society of London last February, says: "As compared with cancer in the breast, the disease in the throat is in some ways more favorable for cure; in other ways, less so. Primary disease of the breast is by far the more favorable of the two, for there it is fully exposed to view, and there is plenty of room for its free removal without endangering important structures. In the mouth and throat, on the other hand, the disease is close to if not involving many important parts, the space in which one has to work is very limited, any considerable margin of healthy tissue can not be obtained, and the early spread of the cancer to muscle, especially in the case of the tongue, tends to distribute it over a considerable area. In the throat, moreover, the disease is much less favorable for operation, because the septic element comes

\* *Lancet*, February 15 and 22 and March 14, 1896.

into play, and thus, instead of having to do with an operation as in the breast, where the mortality is practically *nil*, we have to face a very considerable risk of death from septic disease. On the other hand, cancer of the mouth and throat is more favorable as regards the glandular deposits, for in the neck we have an extensive glandular area exposed to view which can be much more thoroughly dealt with than in the case of the breast. It is true that many surgeons look on the glandular trouble as a most serious part of the disease. With this I do not agree. In another respect cancer in the throat is more favorable than in the breast—namely, that in it metastatic deposits are infrequent.”

With regard to the neighboring lymphatics, Cheyne believes that they should be removed, as in cancer of the breast. It is seldom that no enlarged lymphatic glands can be felt in these cases, and usually they are of considerable size. Whether they can be felt or not, the lymphatic area should be cleaned out. Unless the lymphatic enlargement is very extensive, or adherent to a variety of structures in the neck, and not merely to the sheaths of the vessels, the operation will be more thoroughly done, and the patient will have a better chance of recovery and cure if enlarged glands are already present.

With regard to preliminary tracheotomy, Cheyne, agreeing with many other excellent authorities, does not believe in the insertion of the tube several days prior to the performance of the main operation. Personally, I do not think his ground upon this question well taken, the objection being that in three or four days after the insertion of the tube there will be a collection of septic matter around it which may get into the trachea after the performance of the main operation. Such an accident could probably be avoided by extending the time between the two operations to ten days or more. It is desirable, however, that this question—namely, when preliminary tracheotomy should be performed—should receive more careful attention than has hitherto been accorded it, as it is without doubt an important factor in the patient's welfare.

These three varieties of operation just described—namely, early thyrectomy with or without partial removal of the larynx, complete removal of the larynx, together with the extirpation if necessary of diseased glands, and, finally, the peculiar management of the trachea illustrated in the case of Dr. Solis-Cohen—may be said to finally represent the most recent additions to our present resources for the surgical relief of malignant disease of the larynx.

There is one question, however, which must challenge attention—namely, the second proposition offered by Mr. Butlin, that every tumor of the larynx suspected to be malignant, of intrinsic origin, of limited extent, and apparently within the reach of free removal, justifies an exploratory thyrectomy in suitable cases, in the absence of infiltration of the surrounding structures and of affection of the lymphatics. Even in the case of so

experienced an operator as Mr. Butlin, this theory has not always proved a safe one, while in the hands of one less well qualified its dangers need only to be referred to. Indeed, probably nothing was further from the intention of its proposer than to advocate the performance of thyrectomy in every case of papilloma or of suspicious intralaryngeal disease. It is safe to say that were such a radical view generally adopted the amount of damage done would far exceed any possible advantage to be derived from the attempted treatment of laryngeal cancer. Mr. Butlin speaks from the standpoint of highest authority in diagnosis, aided by the best advisers that the world affords. After every possible means of diagnosis has been exhausted in such hands, he would then, and not until then, proceed to divide the larynx. It is just here that one of the most vital questions arises—namely, that of positive early diagnosis. Until the means now at our disposal shall have been improved not even thyrectomy will always satisfactorily and at once solve the problem.

Careful attention to some of the minor details relating to these operations, which are more or less new, have contributed not a little to recent success. Without question much good may be accomplished by the selection of patients and by careful attention to the indications for or against operation in a given case. Thus, as to the growth, it should be of undoubted malignancy, located within the larynx, and favorably situated for complete removal with the minimum of injury to the surrounding parts.

Concerning the patient the indications are:

That he should not be too old, that he should be possessed of good vitality, that he should suffer from no physical defect likely to complicate recovery or seriously annoy him afterward, and that his temperament, his intelligence, and his surroundings be such as to make it possible for him to exist with moderate comfort after operation. That these suggestions are not unreasonable is proved by general experience.

Apparently it has not always been the best general surgeons who have obtained the most favorable results in this department. On the other hand, some of the most brilliant work on record has been done by men known principally as laryngologists rather than as general operators; several of whom, let it be said, have operated in connection with general surgeons of well-known ability. No more favorable combination could possibly be made. Doubtless the best preparation for the work would be a thorough knowledge of operations upon the tongue, neck, and lower jaw in general.

It can not be insisted upon too urgently that carcinomatous cases requiring laryngectomy are desperate at the best, both as to immediate and as to ultimate results, and that, with our present limited knowledge of the subject, no amount of caution, however great, will avail in preventing a high percentage of failures. With the sources of danger so numerous, constant, and subtle, it is impossible

that too great foresight or experience be brought to bear against them, or that the urgency of this demand be overstated. In the after-care of the patient, it is not by any means enough that the watchers should be ordinarily qualified in the care of severe surgical cases. Nothing short of special fitness in the department of this particular class of cases will yield the best results.

Next, such accidents as the entrance of septic or foreign matters into the air-passages must be carefully guarded against. The use of the œsophageal tube when intrusted to inexperienced hands has often been the cause of disaster. This part of the management, as proved by the records of failure, requires most careful handling. Another dangerous and preventable accident is the poisoning of the patient by the antiseptic dressings, among which iodoform has been the principal offender. The substitution for it of a mixture of equal parts of powdered iodoform and boric acid, or of the compound tincture of benzoin, has been attended with success.

In reviewing the recent progress in the treatment of malignant disease of the larynx, and in studying the manner in which these advances have been made, it must be apparent that nearly all have been the result of long and close study of the subject by accomplished surgeons, whose opportunities for clinical study have been unusually great. The time has long passed which an unsuccessful attempt at laryngectomy by one not fitted for the work can bring anything but reproach to the operator and discredit to the operation.

I am strongly of the opinion that, for a time at least, both the welfare of patients operated upon and the interests of science demand that the indiscriminate performance of capital operations upon the larynx should cease. In most great centres there are individual surgeons or groups of operators who are especially well fitted, as to both personal qualifications and hospital facilities, for the successful performance of this work, as has been proved in many cases by the records which they have already made. Let such men surround themselves with the proper assistants, let them systematize their efforts, and use all diligence in the perfection of appliances and methods and in the study of the cases under them, and keep careful and accurate record of everything pertaining to the history of their work. Then resign to them temporarily the care of as many cases of laryngeal cancer as possible. When a sufficient amount of material has thus been collected, we shall learn whether the radical extirpation of laryngeal epithelioma is unjustifiable, or whether, as we have the best reasons for hoping, it is likely to establish for us a reliable means of cure.

Finally, with the best results obtainable, it should not be forgotten that in this disease surgery is and probably always will be a forlorn hope, and that until we have discovered some better method of dealing with it, the results of operation, even under the best conditions, will fall far short of a perfect means of cure.

## INTUBATION IN THE ADULT.

WITH SPECIAL REFERENCE TO  
ACUTE STENOSIS OF THE LARYNX.\*

By W. E. CASSELBERRY, M. D.,

CHICAGO,  
PROFESSOR OF THERAPEUTICS AND OF LARYNGOLOGY AND RHINOLOGY  
IN NORTH-WESTERN UNIVERSITY MEDICAL SCHOOL;  
LARYNGOLOGIST AND RHINOLOGIST TO ST. LUKE'S HOSPITAL;  
LARYNGOLOGIST TO WESLEY HOSPITAL, ETC.

THE treatment of chronic stenosis of the larynx, especially of the syphilitic type by means of intubation, has been discussed by Dr. Joseph O'Dwyer,† who early adapted his method to adult cases, and reported, in 1886, a case of chronic syphilitic stenosis of the larynx treated by means of intubation. Later, before the Ninth International Medical Congress ‡ at Washington, he related additional and similar experiences and dwelt upon the technique of the operation.

Dr. George M. Lefferts,§ also with special reference to syphilitic stenosis, opened a discussion on the subject before the Tenth International Medical Congress at Berlin, and again, in 1893, he presented a comprehensive paper to the American Laryngological Association || entitled *Intubation in the Adult*, but in that paper the management of acute conditions received but cursory consideration.

At the Eleventh International Medical Congress at Rome, Dr. Schmiegelow,^ of Copenhagen, opened the discussion by a paper on Laryngeal Intubation in Adults. He introduced his remarks by the statement, "Intubation can not replace tracheotomy and be adopted as the principal method of treating acute stenosis in adult patients, but may claim many successes in the treatment of chronic stenosis."

Dr. W. K. Simpson,¶ Dr. Max Thorner, and others have reported isolated instances of a chronic nature similarly treated.

Intubation with reference to laryngeal stenosis of tuberculous origin, which customarily assumes a chronic form, has received attention from Dr. F. E. Hopkins,‡ Dr. Charles H. Knight,† and others. But beyond mere reference to an isolated case here and there, very few in all, I have failed to find recorded any extended notice of the management of acute stenosis of the larynx in the adult by means of intubation.

My own experience embraces four cases—three of

laryngeal diphtheria and one of acute oedema of the larynx, which, having been detailed in a preliminary report, will here with be presented only in abstract. To these I append, through the kindness of friends, two other cases previously unpublished—one of laryngeal diphtheria and one of obscure origin, making six in all.
